

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

LECTURES ON MEDICAL JURISPRUDENCE,

DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,

At the University of London; Session 1834-35.

LECTURE XV.

GENTLEMEN—When the lungs and the heart, still attached, have been wiped clean, they are to be placed in a gentle manner in the water, which should be of a temperature of 60 deg. Faht. If they float, the manner of their floating, whether near the surface, or in the middle, or near the bottom of the fluid must be noted; and whether the lungs turn uppermost; if they sink, whether they fall quickly or slowly to the bottom of the jar. The heart is next to be separated from the lungs, having tied the pulmonary vessels; and the lungs alone being placed in the water, great attention must be paid to the position which they assume, and whether they sink rapidly or slowly, or float near the surface; and what effect, in these respects, the reversing their vertical position produces: and it must also be noticed whether one part sinks more than another, for a reason which I will afterwards mention. On separating the lobes, you must also carefully note whether one lobe float and the other sink; for in the early death of a newborn child, both the lobes are not equally dilated; and we should note whether it is the right or the left lobe that sinks. On cutting the lungs in pieces, if some portions sink, it is of importance to note down not only to which lung these portions belong, but from which part of the lobe they are taken.

Such is the mode of conducting what is called the *hydrostatic test*; and from its simplicity, and the accuracy of the principles on which it is founded, one would, *a priori* imagine that no objections could be raised to the conclusions drawn from it; but this is not the case; and as this is one of those tests to which the attention of counsel is chiefly directed, it is essential that the medical witness should be perfectly aware of the

nature of these, and ready to reply to every interrogation respecting them.

The first objection is raised upon the possibility of the lungs swimming in water, although the child be not born alive, as for instance, if the mouth should present at the dilated orifice of the uterus. It has been supposed that, air being admitted per vaginam, the infant may breathe in this situation; and obstetricians, as for instance, Idena, Croezer, Schmitt, Osslander, Siebold, and Thilenius, have even maintained the possibility of a child crying in this position of things; but no British obstetrician has verified these assertions, and I do not hesitate to say that I do not believe that it ever occurred. I have even some doubts, although not so strong, respecting vaginal respiration, a circumstance in which Capuron believed. The assertion of Dr. William Hunter is of a very different stamp, that a child may breathe when the head only is protruded, and yet lose its life before the body is borne; and, in this case, if the infant "make," says Dr. Hunter, "only one gasp, and instantly dies, the lungs will swim in water, as readily as if it had breathed longer, and had then been strangled." That a child will breathe whilst the head only is protruded, is well known to almost every accoucheur: but I know of few reasons which would act so forcibly, unless violence were employed, as to destroy a child under these circumstances: still, however, it is an objection which may be brought forward to the hydrostatic test. Indeed, a well authenticated case of this kind is recorded by Dr. Hosack, and quoted in Dr. Beck's Medical Jurisprudence. We must admit the possibility of the fact, and although a portion of the lungs may be inflated, and swim in water, yet, if the examination be carefully made, and on separate portions, we will probably find that the buoyant portion is very limited. This was the cause of the swimming of the foetal lungs in the case of an infant born of a woman of the name of Margaret Dickson, who was hanged at Edinburgh, in 1728, for the supposed murder. It is a singular fact (and it almost appears like the interposition of a merciful Providence), that the poor woman, who was put into a cart after she was hanged,

to be taken to her friends at Mussleburgh, a fishing village six miles from Edinburgh, was actually resuscitated by the jolting of the cart over a rough road, and survived many years.

Another objection which has been brought forward is putrefaction. There can be no doubt that putrid lungs will float, when, from the extrication of much gas, lungs even of the foetus at six months will float; but it must be recollected that the entire body requires to be in a high state of putrefaction before the lungs can be affected, and, therefore, no error can arise from this cause: and that the lungs resist the putrefactive process much longer than any other organ of the body. It is also easy to perceive when they are in this state, by making incisions into them; for if putrefaction has taken place, it is obvious by the air-bubbles, which form, as it were, strata between the ramifications of the bronchiæ visible to the eye; which is not the case in lungs dilated by respiration. It is easy also to determine whether the gas contained in the lungs be the consequence of putrefaction or respiration, by pressing strongly a portion of the lungs, and then placing them in water: if respiration has been exercised in such lungs, the portion thus treated will float; but, if the gas be the consequence of putrefactive decomposition, it will sink. There is no crepitation in a lung under putrefaction, when it is compressed by the fingers, or cut into; and this, consequently, is another circumstance that is likely to prevent an erroneous judgment being formed.

It has been stated by one distinguished obstetrician, M. Lecieux, that when the child is extracted by the feet, and the pelvis very narrow, the lungs are apt to float in water, although the foetus had not respired, and had died during the birth. This he attributed to the lungs suffering contusion, and extravasation of blood taking place, from which bubbles of gas are disengaged, and the portion of lung consequently becomes specifically lighter.

A third objection to the hydrostatic test has been suggested by Dr. William Hunter, whose great humanity led him anxiously to find out circumstances which might operate to the advantage of women accused of infanticide. Dr. Hunter imagined that the lungs might be artificially inflated, either by the mother herself, or by others who may have "a diabolical intention of bringing about the condemnation of the mother." If the lungs of an infant be thus inflated, there is no doubt that they will float in water; but the arteries are not dilated by this artificial inflation, nor the actual weight of these organs actually augmented, which are the consequences of respiration. It must also be admitted that the lungs have occasionally sunk in water, although the infant has lived and respired for several hours after its birth. Many of the most

distinguished obstetricians have confirmed this fact from their own experience; and Schenk, relates the case of a child who lived four days, and cried several times, and yet, after death the lungs sunk in water: a circumstance which has been referred to disease of the lungs, of a tuberculous kind, or a congestion of blood preventing the whole lung from being inflated.

Upon the whole, it appears that the only valid objection to the hydrostatic test, is the possibility that the lungs may have been artificially inflated with air blown into them; and this, as I have already stated, can be detected by the absence of that sanguineous dilatation of the lungs, which is the consequence of real respiration. The pulmonary arteries, before respiration has taken place, are in a collapsed state, and dilate after it is established, their branches becoming full of blood, and adding an additional weight to the organ; but no such circumstance follows artificial insufflation.

Having given you a description of the hydrostatic test, its advantages, as affording the means of ascertaining whether a child have been born alive, which has been found dead, and is suspected to have been murdered, and having pointed out to you the objections which have been raised to this test I have now to bring before you the other tests connected with the state of the lungs, that have been suggested as well calculated to throw light upon cases of infanticide.

Ploucquet having remarked the difference in the state of the pulmonary artery, in children who are still-born and those who have respired, justly conceived that a considerable diversity must exist between the relative weight of the lungs to that of the body of the infant in these cases; and therefore, in 1782, he proposed this as a test of a child having respired, or been born dead. His experiments were made on three children only; but from these, he concluded that the relative weight of the lungs in a still-born child, is as one to 67 or 70; in a child that has breathed, as 1 to 35, or exactly double the weight. The simplicity and apparent accuracy of Ploucquet's test attracted great notice; and many were so sanguine as to suppose that the precise weight of the lungs in the foetus before and after respiration had taken place, might be determined, so that it would be necessary merely to weigh the lungs, in order to pronounce that respiration had or had not taken place. The general principle upon which this test is founded is undoubtedly correct; before respiration has taken place, very little blood passes through the lungs; but after this function has commenced, and the whole mass of blood passes through the lungs, it must be perfectly obvious that their weight must be augmented. Correct as the general principle appears to be, it is nevertheless true that it admits of many exceptions; and subsequent investigations

by Schmitt at Vienna, M. Chaussier in France, and Hartman in Germany, threw some obstacles in the way of Ploucquet's test being adopted, except as a proof to verify conclusions already drawn from the hydrostatic test. Schmitt found that the mean relative weight of the lungs in still-born children is as 1 to 52; Chaussier as 1 to 49; and Hartman as 1 to 59; Schmitt that the mean relative weight in children who had breathed was 1 to 42; Chaussier as 1 to 39; and Hartman as 1 to 48. Still it was apparent that the relative weight of the lungs in a child that had respired was considerably greater than in a still-born foetus; and although this had been overstated by Ploucquet, yet the test was a certain one. Other objections, however, were raised, of which it is necessary that you should be aware. Thus, a barrister instructed upon this subject might inquire whether there is a constant relation between the weight of the body and that of the lungs; or, whether the smallness of the cavity of the thorax may not occasionally repress the natural growth of the lungs. There is, undoubtedly, much point in these objections; but it may be justly stated that exceptions of this kind do not militate against a general rule; and that, in every instance, some difference must exist, although not to the extent pointed out in well formed children.

Another objection had been raised, on the supposition that a congestion of blood might occur in the foetal lungs, which would increase their weight; and, if they were also artificially inflated, they would swim; and thence, there would be no means of distinguishing between them and the lungs of a foetus which had respired. Ploucquet himself replied to this objection; and justly remarked that no congestion of this kind can possibly occur whilst the foramen ovale and ductus arteriosus remain pervious: thence that it could not exist in the foetus. It is indeed difficult to conceive how such a congestion could occur, whilst the foramen ovale and ductus arteriosus remain pervious. The most probable opinion is, that the blood flowing from the mother to the foetus is divided into two equal parts, in order to pass through these inlets to the cavities of the heart; and, if this be correct, how can congestion ever occur in the foetal lungs? With regard to the artificial inflation of the lungs of a still-born child, it is true that lungs so inflated will swim: but it is equally true, that no inflation, after the death of a child, can fill the ramifications of the pulmonary vessels with blood; and thence, although the lungs may swim, yet they will be found to weigh less than the lungs of a child of the same weight who has respired.

In a case, which is mentioned by Roederer, a foetus remained eight hours in the vagina, owing to the constriction of the os uteri: it moved slightly after birth and then died.

The aorta and heart were found distended with blood; the pleura was red and highly congested, whilst the vessels of the brain and those of the abdomen were nearly empty, owing to the great determination to the chest; yet, in this case, the pulmonary artery is presumed to have remained in its usual state, as no mention is made of it; which would not have been the case had it been otherwise, under the examination of so accurate an observer. Other cases confirming this observation might be adduced; it is therefore probable that the pulmonary arteries, although they may suffer a slight dilatation, when the other thoracic vessels are gorged with blood, yet, they are never so much dilated as to increase the weight of the lungs in a ratio equal to that produced by the act of respiration.

To ascertain the effect of putrefaction in falsifying the test of Ploucquet's, Dr. Beck made several trials in cases both in which no putrefaction had taken place, and in some in which it had occurred. In two cases, in which respiration had evidently taken place, he found the relative weight of the lungs as 1 to 35½, and 1 to 37½, approximating very closely to Ploucquet's observations: in three cases, in which the putrefaction of the body was advanced, although the lungs were sound, Dr. Beck found the proportions as 1 to 46½; 1 to 29; and 1 to 39 5-7ths, demonstrating that the putrefaction of the body has a considerable influence in modifying the relative weight of the lungs, and consequently in rendering Ploucquet's test fallacious: and in employing it to verify conclusions drawn from the hydrostatic test, it is necessary to inquire accurately into the state of the body. If putrefaction have taken place before the body be examined, no confidence can be placed on Ploucquet's test, the *docimasia pulmonaris*, as it is termed. In ordinary cases it may be resorted to as one of the various tests, on the general accordance of which our decision is to be founded; it is of little value as an isolated test, but of considerable value when confirmative of the results of other tests.

The descent of the diaphragm has also been regarded as demonstrating the previous existence of respiration. This is true, and to one accustomed to the examination of the bodies of children it must be very obvious and may aid greatly in confirming the results of the other tests; but as it is not so obvious as to be easily recognized by one unaccustomed to dissection, it can only be regarded as a secondary test. One more likely to prove useful is grounded upon the relative size of the liver before and after respiration has taken place. In the foetus before birth, the liver fills the whole of the left hypochondrium, and the greatest part of the umbilical region; but when respiration occurs, the size of the liver is greatly diminished. Now, it is easy to account for this change, since it is evident that if the lungs enlarge by respiration, and the diaphragm descend, the pressure upon the liver must be sufficient to diminish

its capacity and press out much of the mild, viscid bile which fills its ducts before birth. Before birth, also, the liver receives a large supply of blood, but as soon as the respiratory circulation is established, the change necessarily diminishes the size of the liver, a smaller quantity of blood being sent through it; and this, added to the pressure from the permanent dilatation of the lungs, and the descent of the diaphragm, certainly affords a test on which some reliance may be placed, in conjunction with other tests; but if taken alone it is at best an uncertain diagnostic sign. Dr. Beck has proposed to weigh the liver, and, by a comparison of its weight with that of a child who had respired, some support might be afforded by this means to the *docimasic test*. Thus, if the lungs were found of the proper weight, and the liver diminished in weight, there could be no doubt that the child had respired: but if the liver was still as heavy as in the still-born fœtus, although the lungs were inflated, and floated on water, there would be then, according to Dr. Beck, reason for suspecting the inflation had been artificially produced. But Orfila, from subsequent experiments, has ascertained that no confidence can be reposed on the relative weight of the liver, as he found it, in some still-born children, to weigh considerably less than in children who had fully respired.

It has been stated, that the empty or full state of the urinary bladder, and the dis-

charge of meconium, are, also circumstances which indicate the vitality of the fœtus, at birth, or its having been still-born: but both these conditions are of a doubtful character. In many instances, the bladder of urine has been found empty, in a child who has never respired: and with respect to the discharge of meconium, we have not only the authority of Dr. Denman, that it occasionally happens before birth, but, in a fœtus of only six and a half months, gestation, which I exhibited to the class last session, the meconium was already discharged, although the fœtus was extracted from the uterus of the dead mother.

Upon the whole, in taking a retrospect of the various proofs by which it may be known whether a child has breathed, and consequently lived after birth, it is clear that a judicious practitioner will not rely upon any single test, but form his opinion on the combination of the most important tests, as these are supported by one another. Those of the descent of the diaphragm, and the size of the liver are first to be observed and carefully noticed; and afterwards, if the state of the lungs, the floating or sinking in water, and the dilatation or the collapse of the pulmonary artery correspond with these appearances, we can have little hesitation in pronouncing a decided opinion, either that the child has respired, or that it has been still-born.

LECTURES ON THE INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF
MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE VIII.

Continuation of the Tissues.

THE *Mucous Membranes* again constitute, as it were, the internal skin of the body, lining every canal which opens directly or indirectly upon the surface. One department of these Membranes, called the *Gastro-pulmonary*, enters, in man, by the nostrils and mouth, extends from the former to the various sinuses and cells communicating with them, and, by the nasal ducts, over the anterior part of the eye-balls, and thence into the substance of the Lacrymal Glands; and from the latter, first into the substance of the three pairs of Salivary Glands, and into the tympana of the ears, and afterwards, on the one hand, by the air-passages into the substance of the lungs, and on the other, by the gullet through the stomach and small intestines—whence it passes, partly into the gall-bladder, and partly into the substance of the liver and pancreas—and lastly, through the large intestines, to terminate at the anus. Another division of these Membranes, called the *Genito-urinary*, enters, in both sexes, by the urethra, whence it passes to line the urinary bladder and ureters, terminating at length in the substance of the kidneys; and as, in the female, a portion of this membrane is continued from the pudendum, up the vagina, to line the uterus and Fallopian tubes; so, in the male, a portion of it proceeds from the urethra, through the prostate gland, partly into the vesiculæ seminales, and partly along the vasa deferentia, into the substance of the testicle. There is likewise, in both sexes, a third comparatively inconsiderable department of this membrane, called the *Mammary*, which, entering by the

ducts of each nipple, extends into the substance of the *mammæ* or *mammillæ* (a). Of course, in all tribes of animals, except mammals, the gastro-pulmonary is commonly the only mucous membrane; since the genito-urinary is either wanting, or falls in general into the former by means of a cloaca, and the mammary does not exist. The collective area of the mucous tissue is probably greater than that of any other partially distributed tissue, or perhaps of all the other partially distributed tissues, in the body; as will be readily admitted when it is considered that—to say nothing of the numerous plaits into which it is in most places puckered—the extent of the internal surface of the lungs alone, which constitutes a fraction only of but one department of these membranes, has been estimated to exceed that of the external surface of the body, from thirty to one hundred times (b), and that the ducts of each of the several proper conglomerate glands, lacrymal and salivary glands, liver, pancreas, kidneys, testicles, *mammæ*—all which consist essentially of mucous tubes—may be drawn out, it is said, many thousand feet (c). To this tissue the teeth, which are, in fact, when they first show themselves in the animal creation, little more than ossified or cornified papillæ, and only very gradually approach the jaws, into which they at length insinuate themselves—appear to bear nearly the same relation, as to the Dermoid Tissue, the *Corpus Mucosum*, with the hairs and nails, and indeed in some animals, as the turtle, (*testudo*, 33), they constitute merely two rough horny plates; in others, as the whale (*balæna*, 42), a series of horny bristles, called whale-bone; while in others, lastly, as the crocodile, (*crocodilus*, 35), they are almost undistinguishable, as well as the tusks of many mammals, either in structure or form, from true horns. The Epithelium, in the meantime, with which the mucous membranes are in many places invested, seems to be strictly analagous, in like manner, to the cuticle or epidermis (d). With respect to the *Serous Membranes*, they occur each in the form of an isolated shut sac; one only, and that in the female alone—namely, the peritoneum, at the two points where the Fallopian tubes terminate upon it—being indirectly open in man, and are interposed between containing and contained parts, whenever a sliding motion is to be carried on. Of such sacs are constituted the right and left pleuræ, the pericardium, the peritoneum, the two tunicae vaginales, the arachnoid coat of the spinal cord and brain, the sinovial membranes, corresponding in number to the moveable joints of the body, and the several bursæ mucosæ, as they are called, whether about the joints, or under the integuments, the whole number

(a) It is denied by some authors that the continuity of the Mucous membranes is so unbroken as it has been represented by Bonn and his followers; Gordon and Ribes, for example, questioning whether any such membrane be continued over the cornea; and Chaussier, Ribes, and Madame Boivin, whether the uterus have any such lining. The opinion of Bonn is, however, much more generally adopted. At the same time, it is proper to keep constantly in mind, that the mucous tissue, in its several ramifications, is similar only—not the same; and that the general axiom of Milligan, that “no reasoning from similarity of tissue is ever correct, except when that similarity extends to vital and functionary properties,” is here particularly applicable.

(b) The former was the estimate of the second Dr. Monro, the latter more lately that of Lieberkuhn.

(c) Thus by Monro, the ducts of the testicle are said to be five thousand feet long, while by Ferrein, those of the kidney are represented as not less than sixty thousand feet in length. We have only to multiply the most moderate of such estimates, for a gland of any given size, by the collective size of all the conglomerate glands of the body, to be satisfied that the surface of the mucous tissue must be stupendous; and that, whether the view of some pathologists, who habitually refer all diseases to these mem-

branes, be true or false, it is certainly not, as has been sometimes represented, a circumscribed one.

(d) This analogy, and the essential differences between teeth and bones—with which they had always previously been confounded—were pointed out first by Coiter, and have been successively insisted upon since by Bonn, Walther, Lavagna, Serres, Geoffroy St. Hilaire, Mayer, Heusinger, and many others. It is sufficient to notice here, as distinguishing the teeth of man from proper bones, their mode of formation, their renewal once and sometimes twice, their heterogeneous structure, their great density, their want of periosteum, and their total immunity from the general diseases of bones, such as Rachitis and Mollities ossium. The reputed caries of teeth is no argument for their organic structure; since false teeth not unfrequently undergo a similar change, which, in fact, is rather a kind of chemical decomposition than ulceration. It is a singular fact, moreover, and one that serves to strengthen in some measure this analogy between the teeth and hairs, that in most of the cases in which the former have been deposited in unnatural situations, as the stomach, urinary bladder, kidneys, ovaries, and testicles, a mass of hair has been found to accompany, and often to envelope them.

of which is between two and three hundred. The collective area of this tissue appears to be considerably greater than that of the dermoid, but in a much greater degree, perhaps, it falls short of that of the mucons (*a*). Lastly, the *Fibrous Membranes* do not line either open canals, like the mucous, nor shut cavities, like the serous; but, on the contrary, are connected, on both surfaces, by cellular tissues, to the contiguous organs. They constitute, in man, the inner covering—that below the serous, when this is present—of all the solid viscera, lungs, liver, pancreas, ovaries, testicles, and so forth; they form the outer coat of all the air-passages and ducts of glands, as well as of all arteries, veins, and lymphiferous and chyliferous vessels; it is of these that all the membranes of the foetus are composed; they constitute all the coats of the eyes, with the exception of the conjunctiva, iris, and retina, and the membrane of the labyrinths of the ears (*b*); and it is of them finally, that the dura mater, the pia mater, and neurilema of the several nerves, the periosteum, external and internal, the perichondrium, the ligaments, the tendons, the fasciæ, and the aponeuroses all over the body are composed. The extent of the area of the fibrous membranes, insensibly sliding as they do into the common cellular tissue of the body, cannot be estimated with any thing like precision, but it is certainly very considerable.

The *Vascular Tissue* is not met with in quite the lowest tribes of either plants or animals, the substance of the bodies of which is in general a uniform gelatinous mass; and even in those in which a motion of fluid is first perceptible, it is rather through tubular excavations in this substance, than through a proper vascular tissue, that this takes place. In the higher orders of plants, however, a regular vascular tissue presents itself, but, formed as it is, like the membranous tissues, exclusively from the cellular, it is of nearly the same character in whatever description of vessels it is found. In most of the higher tribes of animals, on the contrary, it is distinctly divisible into the three varieties of arterial, venous, and lymphiferous or chyliferous, to which may be added the parenchymatous or the erectile (*c*). Of the three former, each consists of two distinct layers, which constitute the middle and internal coats of the vessel; its external coat, when it exists, being always formed, as has been just observed, of fibrous membrane; so that, though an artery, a vein, and a lymphiferous or chyliferous vessel is correctly described as consisting in general of three coats, the proper arterial tissue, venous tissue, and lymphiferous or chyliferous tissue, comprises only two.

(*a*) It is proper to observe, that by some modern physiologists—Rudolphi among the rest—the serous tissue is described as unorganized, like the Epidermis or Epithelium, and whatever vitality it appears to possess, is attributed to the parts which it immediately invests, and which, from its tenuity, have been identified with it. If this doctrine become established, we must of course cease, as indeed many of the continental pathologists have already done, to speak of these membranes as the immediate seat of disease.

(*b*) It is not unusual to call the Chorion and Amnion, the Hyaloid membrane, and the membrane lining the labyrinths of the ears serous, rather than fibrous membranes, probably for no better reason than because they contain serum, which, by the way, serous membranes in a state of health never do; while the dura mater, a truly fibrous membrane, and the Pericardium, a truly serous one, are each, in general, called sero-fibrous, the former from its being invested by the Arachnoid, and the latter from its being covered by a fibrous expansion interposed between its rough surface and the conti-

guous parts of the Pleuræ. It is to confound all distinctions, after having established them, so to denominate the parts in question.

(*c*) The arteries and veins were among the *ὁμοιομερῆ* of Galen. The chyliferous vessels were long confounded, as by Erasistratus and Galen, with arteries, *αρτηριαὶ γάλαχτος πληρεῖς*—and the lymphiferous, as by their reputed discoverer, T. Bartholin, (1653) with veins—*venæ aquosæ*; but their pretensions to be regarded as formed of a distinct tissue, were at length established by the Hunters, (1762), Cruikshank, Hewson, and Mascagni. The Parenchymatous, or Capillary tissue—a very different thing from the *παρεγχυμα* or sponge of Erasistratus, as well as from the *Parenchyma*, or fancied folliculi, cryptæ, loculi, cotylæ, utriculi, &c., of Malpighi—was regarded as a separate tissue, first by Bichât; and the Erectile lastly—for a long time mistaken for cells in which arteries in some parts of the body were represented as terminating, was constituted a proper tissue, first by Dupuytren, Richerand, and Bèclard.

The following, then, are the principal characteristics—

	<i>Of an Artery.</i>	<i>Of a Vein.</i>	<i>Of a Lymphiferous or Chyliferous Vessel.</i>
The middle coat.	Composed of dun-coloured, opaque, and somewhat spongy, but tough and very elastic fibres, a little flattened, and placed like rings round the bore of the vessel (a).	Composed of flesh-coloured, semi-transparent, very dense, but almost inelastic fibres, nearly cylindrical, and running longitudinally with respect to the vessel.	Not easily separated, but similar, at least in its thickness, relatively to the bore of the vessel, to that of an artery.
The internal coat.	Transparent, dense, elastic, and without fibres or folds (b).	Semi-transparent, spongy, inelastic, slightly fibrous, and often laid in folds, constituting valves.	Not easily separated, but similar, at least in the structure of its valves, to that of a vein.

The Arterial and Lymphiferous or Chyliferous Tissues become gradually more rigid and unyielding as age advances, and are naturally more so in males than in females, while, on the other hand, the Venous Tissue becomes gradually less so in the progress of life, and is at all times less so in males than in females, so that the proportion of arterial blood, lymph, and chyle, is greatest in children and females, and that of venous blood in old persons and males. The proper Arterial System may be said to begin in man at the radicles of the Pulmonary Veins, to extend through the left heart, and to terminate at the extremities of the arteries of the system of the aorta; the proper venous system to begin at the radicles of the veins of the system of the Venæ Cavæ, to extend through the right heart, and to terminate at the extremities of the pulmonary arteries (c), and the Lymphiferous or Chyliferous System lastly to begin, like the Venous, at their radicles in the parenchyma, and to terminate by two mouths—one on each side—in the system of the upper Venæ Cavæ near the point where it reaches the right heart. The collective capacity of the proper arterial system is computed to be equal, in an adult human being, to about one quarter of that of the Venous, and one half of that of the Lymphiferous or Chyliferous; so that, estimating the quantity of the blood in the body, at any given time,

(a) This is the coat of an artery, concerning which so long and tiresome a controversy has been maintained, some physiologists confidently asserting, while others as confidently deny, its muscularity. The arguments on either side hinge more on the vital than on the physical evidences of this property, and will fall therefore to be considered more at length in future. In the meantime, however, it may be observed that every physical evidence seems to be against the presumption of their muscularity; the muscular tissue being in general red, yielding, inelastic, and composed of cylindrical fibres, whereas the coat in question is dun-coloured, tough, very elastic, and composed of fibres more or less flattened. By some physiologists it is represented as a variety of the tissue, described for the first time in 1822, by Hauff, under the name of *Tela Elastica* or *Flava*—the *Tissue élastique* or *jaune* of the French zoologists—other examples of which occur in the *ligamentum nuchæ*, the *ligamentum flavum*, the immediate envelope of the spleen and other erectile organs, and elsewhere; but there appears hitherto to be no good reason for regarding it otherwise than entirely *sui generis*.

(b) This coat of an artery is often, but very incorrectly, called its serous coat, and it is really amusing to hear persons who admit that the external coat of an artery is

fibrous, and describe its middle coat as muscular, and its internal coat as serous, gravely at the same time talking of an arterial tissue. The internal coat of an artery is allied, not only in its physical characters, but in its liability to certain diseases, to a serous membrane, as the inner coat of a vein is to a mucous membrane; but they are merely allied to, not identical with, these structures.

(c) The former is the *Système à Sang rouge*, the latter the *Système à Sang noir* of Bichat. Before the time of Harvey the pulmonary veins were always called arteries—the *arteriæ venosæ*—and the pulmonary arteries veins—the *venæ arteriosæ*—and the change of names, which he introduced, was certainly any thing but judicious. The properties of its contents, the nature of its tissue, and the character of its diseases, are surely better foundations for the name of a vessel than the accidental circumstance of the blood flowing through it either from branches to trunks, or from trunks to branches; and in all these respects the so called pulmonary veins are strictly arteries, and the so called pulmonary arteries, veins. If the opposite principle be adopted, what, it may be asked, is the *vena portæ*? It is a vein at one extremity, and an artery at the other.

as thirty pounds, the Arterial System will contain six, and the Venous System twenty-four—while there will be, at the same time, about twelve pounds of lymph and chyle in the Lymphiferous or Chyliferous Systems. The whole extent of these Tissues, then, exclusively of the Parenchymatous and Erectile, must be very great. The *Parenchymatous* or *Capillary Tissue* comprises the net-work of minute vessels in which the proper arteries, or in the lungs, veins terminate on the one hand, and from which the proper veins and lymphiferous or chyliferous vessels, or in the lungs, arteries begin on the other. It is known rather by its actions than by its structure, to be distinct from the proper tissue of any one of these systems of vessels, since the vessels of which it consists are too minute to present any distinct physical characters; its actions, however, are such as pretty obviously indicate in these vessels a co-existent muscular coat (a), although, as it is impossible to believe that they consist exclusively of this, the admission of a proper Parenchymatous Tissue was not improper. The Parenchymatous or Capillary Tissue—as the seat of all the molecular actions of the body—is of course universally distributed, and indeed, so copiously interwoven probably with all the organized Tissues, that it constitutes a great part of their bulk and weight. The *Erectile Tissue*, lastly, is little more than dilatable parenchyma—that is to say, a net-work of extreme arteries, and incipient veins and lymphiferous vessels—chiefly, however, veins—which are susceptible of sudden dilatation from certain causes, but, on these causes ceasing to operate, immediately return to their original size (b). Of this Tissue are said to be composed all the papillæ of the Dermoid and Mucous Membranes, the thyroid and thymus glands, the spleen and supra-renal capsules, the corpus spongiosum urethræ, the corpora cavernosa clitoridis, the fimbriated extremities of the Fallopian tubes and the papillæ of the mammæ, and the corpora cavernosa penis; its extent, therefore, is pretty considerable. It is not improbable that the several conglobate, or lymphiferous and chyliferous glands consist also of a kind of Erectile Tissue; the principal vessels of which, however, are not, as in the proper Erectile Tissue, extreme arteries and dilatable incipient veins, but extreme lymphiferous or chyliferous vessels meeting dilatable vessels of the same description; and that these glands are thus a kind of diverticula of lymph and chyle, as the organs before enumerated are of blood.

The *Osseous Tissue* (c)—for of the *Ligneous* and *Medullary Tissues* of Plants no particular notice needs at present be taken—it is hardly necessary to observe, is almost proper to the vertebrate tribes of animals, and in some, even of these, as the cartilaginous fishes, the cartilaginous tissue supplies its place. It is in man of a blue-grey colour, opaque and inflexible, consisting of hard plates, which are composed of fibres united together by cellular tissue, the latter, as it approaches the surface of the bone, becoming gradually condensed into its external periosteum, and forming, in like manner, its internal periosteum, if the bone be cancellated or hollow. It constitutes the whole of the proper skeleton, the number of bones of which is, in the adult, about two hundred and fifteen, exclusive of the ossa triquetra and sesamoidea, and all, except the hyoid bone, are more or less directly

(a) The peculiar property which these vessels manifest—the insensible contractility of Bichat—has been distinguished, apparently very superfluously, from that displayed, during their sensible contractions by the more obvious muscles, by Stahl and his followers, Whytt, Cullen, and others, by the name of tonicity, and by Chaussier and Blumenbach by that of contractility, as contrasted by the former with myotility, and by the latter with irritability. If this property, however, be not—as it certainly is not—elasticity, it must be that which is characteristic of muscular fibre, for we have no evidences of the existence, in the living body, of any third source of motion, the muscularity of the parenchyma, if admitted, being quite adequate to explain all the alleged contractions of the cellular, the dermoid, and other tissues, not *per se* possessed of muscular fibres—nay, even perhaps of the middle coat of the larger arteries themselves. It is true the circumstances under which these contractions occur are often very different from those which call the sensible muscles into action; but this may be easily

explained, without the admission of any difference of tissue. The heart, the stomach, and the urinary bladder, all owe their property of contracting to their muscular fibres; but these fibres are called into action, in the different instances, by stimuli of a very different character. This subject, however, will be considered more fully in future.

(b) Of all the five formerly reputed terminations of arteries, then—in veins, in lymphiferous vessels, in the follicles of glands, in the cells of erectile organs, and in exhalents—the two first only can be retained: the folliculi, &c. of Malpighi having been proved by Ruysch to be nothing more than pensils of radiating arteries, coalescing with corresponding pensils of veins, &c.; the cells of Ruysch having been proved by Duvernay, Cuvier, Tiedemann, Ribes, Morreschi, Dupuytren, and others, to be nothing more than dilated parenchyma; and the exhalents of Leeuwenhock having never been seen by any body who did not require them in order to support an hypothesis.

(c) Both bones and cartilages were among the *σποιομενη* of the older authors.

connected together: the average weight of the entire skeleton, including, of course, a great proportion of water, is thirty pounds, or about one-fifth of that of the body.

The *Cartilaginous Tissue*, again—the last of those derived from the Cellular—is of an opaline colour, semi-transparent, extremely pliable and elastic, and of a homogeneous structure, without any appearance of fibres in its undecomposed state: this tissue is sometimes inextricably interwoven with the proper Fibrous, when it constitutes what is called the *Fibro-cartilaginous Tissue*. Of one or other of these are composed, 1, the obducent cartilages, or those which directly cover the extremities of bones at the moveable joints; 2, the inter-articular, or those which are sometimes indirectly interposed between such bones in these situations; 3, the ligamentous, or those which perform the office of ligaments, as at all the synchondrosial joints; and finally, the vicarious, or those which stand in the place of bone, as at the sternal ends of the ribs, in the larynx, trachea, and bronchi, and about the nostrils, eye-lids, and external ears, giving to these organs at once security and pliability. The distribution of this tissue is not however very extensive.

Such, then, is the first Elementary Tissue—the Cellular—with its compounds, the membranous, vascular, osseous, and cartilaginous: of the two other Elementary Tissues—the Nervous and Muscular—each presents two varieties, but neither ministers to the formation of any compounds.

A proper *Nervous Tissue* is certainly not met with in the lower tribes of plants, and the existence of any such tissue, even in the highest, is very problematical, although by some authors the Medullary Tissue (a), and by others the modification of the Vascular Tissue constituting the spiral vessels (b), has been so reputed. By other physiologists some small globules, similar in appearance to those of which the ultimate fibrils of the proper Nervous Tissue of animals have been supposed to consist, and answering in a similar way to chemical re-agents, have been detected about the base of the petiole of the humble plant (c) (*Mimosa*), and regarded as its Nervous system; but if these constitute a proper Nervous Tissue, it is certainly in a very rudimental state. In quite the lowest races of animals also, it is equally wanting; no appearance of it having been hitherto met with in any of the zoophytes, including the Sea-blubber (*Medusa* 4), Sea-hedge-hog (*Echinus* 5), and some others, the degree of organism of which is certainly such as would have led us to expect it (d). In all the higher orders of animals, however, it is uniformly found, and is divisible in quite the highest into two varieties—the ganglionic, or that constituting the system of the great sympathetic nerve, and the cerebro-spinal, or that constituting the spinal cord and brain, and the nerves immediately connected with them (e): the two, however, become more or less amalgamated together as they proceed each from their central parts. Both consist partly of a grey and partly of a white substance, opaque, pulpy, and inelastic, the grey matter being always homogeneous in its structure; the white sometimes homogeneous, at others fibrous, and both supported by a fibrous membrane, called Neurilema, which in the homogeneous nervous substance is flexiform in its structure, and in the fibrous tubular. Between the two varieties of the Nervous Tissue, the principal distinctions are, that

In the *Ganglionic Nervous Tissue*,
The grey and white substances are everywhere—as well in the minutest nervous filament as in the largest ganglion—inextricably interwoven together;

The white matter is always homogeneous; and

There is found, upon analysis, very little oleaginous matter, but some fibrin.

The form of the primitive nervous fibre is said to be cylindrical, and its size about twelve

In the *Cerebro-Spinal Nervous Tissue*,
The grey and white substance are always separated by a decided line of demarcation, and the former is found only in the central parts of the system;

The white matter is in some Nerves—as those belonging to the Respiratory and Motiferous systems—fibrous; and

There is found, upon analysis, much oleaginous matter, but no fibrin.

(a) Linnæus, Haller, Brâchet.

(b) Oken.

(c) Dutrochet.

(d) Very recently, Erhrenberg of Berlin, among other discoveries made with the microscope, has announced that of the existence of a nervous system in all the Infusoria; further observations, however, are required to establish this as a fact. (See Archives Generales for December, 1834.)

(e) The nerves were the last of the above-named *δυσιομεγν* of Galen, who was further the first to restrict the word *Νῆρος* to the sense which it now bears, instead of extending it, as before his time was the custom, to

signify also a tendon or ligament, or even a blood vessel or a muscle. The separate existence of the Ganglionic Nervous System, although known to Galen, was not generally recognized till the time of Willis; and it was not till that of Bichât that the tissue of which it consists was distinguished from that of the Cerebro-spinal System, by the name of Nervous Tissue of Organic Life, as opposed to the Nervous Tissue of animal life. The above terms, however, as founded on physical, and not vital distinctions, and as not implying any hypothesis, have been considered preferable.

times greater than that of the primitive muscular fibre, and it is from the circumstance of the tubular neurilema, which immediately invests this, having been sometimes injected with mercury, that the Nerves have been by some authors represented as hollow (a): it is commonly described as somewhat tortuous in its course, to compensate for its want of elasticity. The collective compass of the larger portions of the Ganglionic Nervous Tissue is comparatively inconsiderable, but that of the Cerebro-spinal is much greater, the spinal cord of an adult man weighing about an ounce and a half, the brain between forty and fifty ounces, and the Nerves immediately proceeding from them being also of considerable size. But it is perhaps chiefly of the minuter ramifications of these two systems that the bulk of the Nervous Tissue is composed, universally as these are distributed, and copiously as, like the Parenchymatous Tissue, they are interwoven probably with every organized tissue of the body, so that they constitute a great part of the volume and weight of each.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS,

FROM BIRTH TO PUBERTY,

BY DR. RYAN,

Delivered at the Medical School, Westminster Dispensary, Gerrard Street, Soho; Session 1834-35.

LECTURE XXVI.

Adhesions of different Organs.

GENTLEMEN—*Adhesion of the Tongue to the Gums.*—Infants have been born with the tongue adherent to the gums, or vicinal parts, by means of ligamentous or membranous cords. The effect of this vice of conformation would be an inability to protrude or retract the tongue, or to form that furrow in it which is essential for suction. If the infant survived, there would be either complete dumbness, or very imperfect speech.

Treatment.—The adhesions should be incised with a pair of scissors. In effecting this object, the nose should be seized between the thumb and index finger, which would oblige the infant to respire through the mouth, and then the scissors could be introduced. The hæmorrhage is generally trivial in such cases; but, if obstinate, the actual cautery should be applied. The cautery should be the last remedy, and only resorted to after pressure, a saturated solution of alum, and other styptics had failed. Such cases are fortunately rare.

Tongue-tie.—When the frænum of the tongue is too short, or when it extends towards the apex of the tongue, the infant cannot suck, or speak at the usual age. This disease is readily detected by introducing a finger into the mouth under the tongue. The evil result of this malformation would be the death of the infant from an inability to suck; and, consequently, from a want of nourishment. An operation is necessary as soon as the disease is discovered; and it is much easier performed on a new born infant, than on one of six or twelve months

old. If the infant can suck well, the operation may be deferred for a month or two; but when speech is impeded, and when reason replaces instinct, the operation, on account of the great chance of docility, will be performed with less difficulty. The faculty of speech usually commences about the sixteenth or eighteenth month, so that an operation should be performed before this age. The operation is simple. The infant's head and arms are to be held, when the practitioner introduces the index finger of the left hand into the mouth, depresses the lower jaw, carries the point of his finger to the root of the tongue, and by the side of the frænum. He then introduces a blunt pointed part of the scissors, and divides the frænum in the middle. He is to avoid cutting too near the root of the tongue, lest he wound the ranine arteries or veins, and cause fatal hæmorrhage, or free the tongue so much as to give rise to retroversion of it, which might cause suffocation—an accident which occurred, according to Petit and Levret. Some advise a sound with a slit in its extremity, or a piece of card slit so as to pass on the frænum; but experience has convinced me that neither is necessary in the majority of cases.

Should the vessels be wounded, a troublesome hæmorrhage will occur, and this will be increased whenever the infant makes suction. Petit proposed pressure on the tongue, which was to be retained by a bandage round the lower jaw to suppress this hæmorrhage, but every one must see the impracticability of such a contrivance. In some cases a saturated solution of alum (about a drachm to an ounce of water will arrest it); should this fail, the actual cautery must be applied. Cases are said to have occurred which required the carotid artery to be tied. Hæmorrhage scarcely ever happens when the operation is performed a few days or weeks after the birth of the infant; and there is most danger of it when the infant is three or four years old, as then it can be kept steady with much greater difficulty during the operation. A practitioner is often requested to cut the frænum when the infant does not suck well; but he will often discover that the cause is a short or

undeveloped nipple, the result of original malformation, or of the injurious custom of tight lacing. In such cases the nipple must be elongated by means of suction made with a breast bottle, or new tobacco pipe, or by a strong infant, or the nurse. When this fails, a wet nurse ought to be provided in all cases, if the parents can afford to procure one. Some infants raise the tongue towards the roof of the mouth, and this prevents them from making suction. In such cases the tongue should be depressed with the handle of a tea spoon, or a spatula, every time the infant is about to be applied to the breast, until it acquires the power and habit of sucking. The tongue may adhere to the vault of the palate, as attested by Lapis, Levret, and Bunel.

In some cases the frœnum may be shorter than natural, but offer no impediment to suction, though it may cause stuttering. The celebrated Demosthenes laboured under this disease. In some instances the division of the frœnum will effect a cure. I have observed this fact in two instances; one was a boy aged nine, and the other a girl aged thirteen years. I divided the frœnum in both, and the power of distinct articulation was speedily developed. I have frequently observed the frœnum of extraordinary thickness and shortness in children whose speech was thick and indistinct. Mr. Warden, of Limehouse, lately consulted me in a case of this kind.

Unions of the Fingers and Toes.—This deformity is occasionally met with; and the union is membranous, somewhat similar to that of birds. Union of the toes is productive of little inconvenience during childhood, but is a serious defect during the adult age, as it may much impede locomotion or walking; but that of the fingers prevents the power of grasping objects.

When the adhesion is firm, it should be separated with a bistoury; but when it is membranous, a pair of scissors will be preferable. After the division of the parts, they should be kept separate by simple dressings and bandages, and re-union prevented.

Union of the Penis and Scrotum.—Petit describes a remarkable case of this deformity. He found in a child of twelve years of age, who died of another disease, that, on inflating the corpora cavernosa, and dissecting the parts with great care, the urethra was very short, ligamentous, inextensible, and without cellular tissue. He extended both extremities of that canal, but on loosening his hold they assumed their natural situations and preserved the original curvature. In fact, the curvature was so great, that had the individual arrived at the adult age, he could not fulfil the end of marriage.

Infants have also been born with the frœnum of the prepuce too short, too thick, or too hard, so as to produce curvature of the glans penis, an impediment to erection, and

to marriage. This disease is of little importance during infancy; and may be remedied in adults by a simple incision. There is scarcely any hæmorrhage, and this can, in general, be readily suppressed by pressure, or cold astringent lotions.

Congenital divisions of Continuity.—It is recorded, but I have not observed such cases, that the bones may be fractured during intra-uterine existence, either by external injuries inflicted on the abdomen of the mother, such as falls, blows, &c., or by a convulsive motion of the muscles of the fœtus, when the bones are diseased. Mollities or fragilitas ossium, the contamination of syphilis or cancer, will often predispose to fracture in the adult, and consequently in the fœtus. The latter cause will explain the existence of fractures supposed to be produced by the imagination of the mother. The cases recorded by Malebranche and others, of infants born with different fractures, and ascribed to the terror of the mother at having witnessed the mutilation of malefactors on the wheel, were satisfactorily explicable by the preceding cause. Women are often frightened in our times, but they seldom bring forth infants with fractures. Infants have been born with ununited fractures of all the long bones (Amand, Chaussier.)

Infants have also been born with consolidated fractures. Fractures may be inflicted by the bones of the pelvis, through which the infant has to pass into the world, or by instrumental or manual operations. The bones of the cranium, lower jaw, clavicle, superior and inferior extremities, the ribs and bones of the pelvis, have been fractured by the preceding causes. Cheselden described fracture of the ribs caused by nurses. Numerous other distinguished obstetricians and surgeons have attested fractures caused by the forceps, lever, or by the operation of version. These fractures are to be treated on ordinary principles.

Wounds of different parts may be inflicted by projecting bones, when the maternal pelvis is deformed, or by artificial delivery. Various obstetric writers attest examples of this kind. (Mauriceau, Delamotte, Saviard, Amand, &c. &c.)

The fœtus in utero has been wounded in homicidal attempts to procure abortion. It has also been wounded after birth, for, the same criminal intent, by acupuncture, or through the nasal fossæ, the orbit, the fontanel, the temple, the ear, the neck, the axillæ, or the region of the heart, the anus, abdomen, vagina, &c. In such cases the traces of blood will alone lead to discovery. Such cases are recorded in the works on forensic medicine. Other parts are divided, as the lip, the palate, the uvula, and the urethra in the male.

Hare-lip.—This term is applied to division of the upper lip, which may be simple, double, or complicated, according as there is one or two slits in the lip, or wher

gum, palatine vault, or uvula is divided, or the divided lip is attached to the gums.

The lip presents a longitudinal, triangular, or irregular cleft, whose edges are round, thick, and covered with a thin roaceous membrane. The cause of this deformity is wholly unknown, and cannot be supposed to depend on the maternal imagination. I have known five cases of ladies who dreaded that their infants would be born with hare-lip, though every one was perfect. Tiedeman attributed this deformity to a certain alteration in the brain, as when it is deprived of some of its median parts; while Oslander and Duges ascribe it, conjecturally, as the effect of some former intra-uterine hydrocephalus. The cause is, however, still unknown, and remains to be determined.

The bad effects of hare-lip are deformity, inability to suck, imperfect nutrition, and defective speech at a future period of life. Moreover, the crying and laughing of the infant very much increase the deformity, and render it hideous.

When the division is prolonged to the palatine vault, the opening permits the ingress of the air into the mouth, according as it is removed by suction, and this prevents the afflux of the milk, or allows it to escape through the nose, and the results are imperfect nutrition, and the decline of the new born infant. It is therefore essential to the preservation of the health of the infant, that relief should be speedily afforded in bad cases.

There is, however, much diversity of opinion as to the proper period for performing an operation to remove this deformity. Rooknuisen, Ledran, Louis, Sabatier, and Duges advised the operation in a few days after birth. Boyer, Dubois, and Capuron consider the fourth or fifth year the most advantageous age, as the lips will be sufficiently firm, the infant more sensible of its deformity, and more docile to support the operation for its removal. Others maintain that the lip is too delicate and tender at birth to retain the needles and sutures, which would cut through it.

If the operation is determined on immediately after birth, it is to be performed by incising the margins of the divided lip with a pair of very sharp scissors, and then passing two or three needles so as to bring the edges in perfect apposition, and secure them by the twisted sutures. The operator must take great care to bring the whole surfaces of the lip in perfect apposition, and especially the lower margins, so as to prevent deformity. Union by the first intention ought to be induced, and this generally takes place. The operation is technically termed *chiloraphy*.

Congenital division of the Palatine arch and Uvula.—This is a very rare occurrence, and was seen only once by the experienced professor, Capuron. The subject was an Ameri-

can gentleman, aged twenty-one years, who was attending his lectures on obstetrics. The professor advised his pupil to consult Baron Roux, who incised the edges with a pair of scissors, united them by means of sutures, which he inserted with a needle fixed in a handle. This operation was successful, and called by its inventor *staphyloraphy*. He has since performed it successfully, and it was lately attempted at the Westminster Hospital in 1834, without success. It can only be performed when the child has reason, and according to some, at the adult age only.

Congenital division of the Parietes of the Thorax, Abdomen, and Genital Organs.—The records of medicine afford examples of absence of the anterior wall of the chest and abdomen, and the viscera floated in the amniotic fluid (*Fried*). The osseous part only was wanting in other cases (*Adelon*), and the heart has been seen covered by the skin only (*Duges*). I have seen two infants whose abdominal viscera were covered by skin alone at birth. Both were born dead. My friend, Mr. Hughes of Holborn, had attended at the birth of one of them, and has it preserved. MM. Capuron and Sedillot, and Borel, record similar cases.

The hypogastric region often presents a red, fungous, painful tumour, which is the bladder, protruding through the abdominal parietes. This is most common in males, and has been termed *exstrophy*. The umbilical cord is inserted near this tumour, the orifices of the ureters are apparent, the pubic bones are separated, the cavernous bodies are distinct, the urethra opens on its superior surface, so that the penis represents a deep groove (*epispadias*). Some cases of distention with danger of rupture of the bladder, are supposed to be the intra-uterine cause of this deformity (*Wrisberg*, *Chaussier*, *Vrolick*). It does not prevent the infant from living, but disqualifies the male for generation.

With regard to the treatment of this deformity, little can be done except preventing the constant discharge of urine, by means of a compress and other contrivances. The genital organs are liable to congenite divisions. The urethra may open on any part of its trajet, from its external orifice to the scrotum, and the disease is named *hypospadias*. When there is an opening on the back of the penis it is termed *epispadias*; and when there is a lateral opening it is called *pleurospadias*.

The first of these is the most common, the others rarely occur.

When the meatus urinarius is obliterated, and an opening supplies its place near the frænum, no operation is necessary, and the individual is capable of performing the act of generation. The infant suffers no inconvenience, as it discharges its urine very freely, and without any annoyance. Some proposed to incise the glans over the site of the natural aperture, then to pass a bougie

or catheter through the obliterated portion of the urethra. This operation is not performed nor sanctioned by modern surgeons. When the aperture is near the root of the penis, the individual will be sterile, and his disease cannot be remedied. Spallanzani impregnated a bitch by injecting the male semen into the vagina; and John Hunter advised a patient who laboured under fistula in perineo, through which the spermatic fluid passed during sexual congress, to collect the fluid and inject it into the vagina. It was said that pregnancy followed; but I do not believe it:—it is barely possible, but extremely improbable. When the scrotum and perinæum are divided, sterility is still more complete; and it is sometimes combined with impotence, on account of the brevity and disfiguration of the penis. Individuals so deformed are supposed to be hermaphrodites, as the cleft situated behind and below the penis bears a rude resemblance to the vulva. M. Duges is of opinion that we may regard this disposition as a presistance of the intermediate embryonary state of the two sexes—so is Dr. Fletcher.

Sabatier mentions a case of the latter malformation, which gave rise to a singular mistake. The infant was supposed to be a female, and was brought up as such, but after some time the penis developed, which at birth was not larger than the clitoris. The scrotum was not apparent, and the testicles had not descended from the abdomen. M. Capuron relates another remarkable case, in which the hypospadias was prolonged to the scrotum; the fissure formed two great lips, each of which contained a testicle, which determined the sex of the infant, and dissipated the illusion. He states that M. Girand saw a case of this kind at the Hotel Dieu, in 1796, which is described by M. Leveille, in his *Nouvelle Doctrine Chirurgicale*. There was a similar case presented at the London Hospitals, in 1834, and many students supposed the individual to be a hermaphrodite. Attempts have been made to cure abnormal apertures of the penis, by incising the edges, inserting a suture, with a view to effect union by the first intention. The operation generally fails. Many of you have witnessed its failure on a late occasion at the Westminster Hospital, and those who have not, will find a full report of the case in my journal. I am not aware that operations have been performed on infants, and I should decline to recommend or perform them, as the deformities are not productive of any inconvenience in early life.

—o—

OBSERVATIONS ON AGUE,

BY LAUNCELOT PAUL, M. D.

(Continued.)

Of Complicated Ague.

By *complicated ague*, I mean ague accompanied with visceral inflammation. The nosolo-

gists will perhaps quarrel with me for calling the disease I am about to describe ague, because it is a form of what is usually denominated remittent fever; but as I am convinced that it differs from ague only, in being combined with local inflammation, I think that the term complicated ague conveys a clearer idea of its nature, and points out more accurately its natural affinities.

The paroxysm of an intermittent has been made, by many writers, the basis of reasoning on fever in general. It has been surmised, that a continued fever is a succession of such paroxysms variously combined, and this notion has been supported by several alleged facts, which I cannot say that my own observation has enabled me to verify. Thus it has been asserted, that ague frequently passes into continued fever; now it is no doubt possible, that any protracted disease, which greatly disturbs the general functions of the system, may induce continued fever; but I must declare that I never saw ague pass, by any thing like a natural transition, into common continued fever—and as I have seen a great many cases of ague, I must conclude that such transition, if it ever occur, is extremely rare, and that ague has no natural tendency to pass into continued fever. It is, however, true, that ague very frequently becomes complicated with local inflammation, and passes into a severe form of *remittent fever*. Again, it has been asserted that continued fever has often, towards its close, a tendency to intermission, and finally resolves itself into ague. I never saw this either. It is true, indeed, that in marshy districts, the state of debility attendant on convalescence from continued fever, renders the patient very liable to ague, and he is frequently seized with it; I conceive it is this fact that has given rise to the notion that continued fever passes into ague—which, as far as I have been able to observe, it has no tendency to do.

The term *remittent fever*, has been somewhat vaguely applied. In most, perhaps in all continued fevers, there are exacerbations and remissions, and these are particularly conspicuous in the fevers of children.

When such alternations are strongly marked, the fever is frequently called *remittent* though it be in fact the same disease with that commonly called *continued fever*. To this the only objection is, that two very distinct diseases are confounded under a common denomination, namely, *continued fever*, in which the exacerbations and remissions are rather more strongly marked than usual, and real *remittent fever*, or, as I call it, *complicated ague*. In continued fever, the exacerbation consists merely in a period of increased heat and excitement, unpreceded by any thing like a cold stage, and the remission consists merely in an abatement of this excitement, not produced by a critical diaphoresis, but

most probably connected with those diurnal changes in the animal economy, of whose nature and laws we are ignorant, though they have a marked influence on the course of diseases. In proper remittent fever—the fever of marshy districts—the exacerbations are much more distinct and violent; they are preceded by a renewal of the cold stage, and are generally resolved by perspiration, the paroxysm being thus terminated, while fever, in a minor degree, is still kept up by the presence of local inflammation. Throughout the course of the disease we can distinctly trace an ague, which is often sufficiently regular in its type, the intermission being filled up with the ordinary symptoms of visceral inflammation. I have never been in the East Indies, but as far as I can judge from description, the marsh remittent of our own country does not differ essentially from that of India, allowance being made for the peculiar influence of a tropical climate on the whole system, and particularly on the liver.

I shall describe the disease as I have seen it; and I may mention that my observations on all the forms of ague have been made chiefly in the marshy parts of Somersetshire. This disease comes on in all respects like a common ague, with rigor and oppression, and very frequently bilious vomiting. During the hot stage symptoms of local inflammation manifest themselves, the seat of the inflammation being various.

It is generally in some of the abdominal viscera, and the stomach is perhaps, on the whole, its most frequent locality, in which case burning pain in the epigastrium, and frequent vomiting, are prominent symptoms—but it is unnecessary to enumerate the well known phenomena of inflammation in the different viscera. The small intestines, liver, and spleen are frequently affected, and inflammation of the kidneys is by no means of unusual occurrence.

The brain is less frequently inflamed than the viscera of the abdomen; when it is so, the phrenitic symptoms are exceedingly violent during the excitement of the hot stage, and the disease, if not checked soon, terminates fatally. Inflammation of the pleura, or parenchyma of the lungs is not very common; in most severe cases of marsh remittent however, the bronchial membrane is more or less affected, and the patient is teased with cough. As the hot stage subsides, perspiration breaks out upon the skin, and the local pain and general distress are much alleviated; but the pulse does not return to its natural standard, and the symptoms of local inflammation, though much abated, still continue. These paroxysms are repeated, sometimes once, and sometimes twice in the twenty-four hours, and in their recurrence we may, in most cases, trace some one of the more ordinary or less common types of ague. One of the most remarkable features in this disease is the great

prostration of strength and spirits, and the tendency to syncope, arguing the presence of some cause which powerfully depresses the nervous energy. The state of the bowels is various; sometimes they are constipated, at others diarrhoea prevails; but in almost all cases the alvine excretions are exceedingly dark coloured and fetid.

I have stated my belief that this disease is ague complicated with various forms of visceral inflammation. My reason for thinking so is, that if the local inflammation be subdued, the disease immediately changes into a common ague, which is as easily arrested by the bark as any other ague. This position will be best illustrated by considering—

The Treatment of Complicated Ague.

As soon as the disease has declared itself, the lancet should be used with promptitude and boldness, and the practitioner should not be deterred from its application by the appearance of debility. The tendency to syncope is often so great that the patient, if bled in a sitting position, will faint before a tea-cupful of blood has been drawn; to obviate this, he should be bled while in a recumbent position, and the blood should not be allowed to flow too rapidly. It is desirable, if possible, to extinguish the inflammation at once; but in this, as in all other fevers, we are not to deal with local inflammation as if it were the sole disease. A large dose of calomel, combined with some other purgative, should be administered shortly after the bleeding, and if the pain be not entirely subdued by the use of the lancet, a blister should be applied; and in a word, we must use vigorously, and without loss of time, those means which are applicable to the case of inflammation as an adjunct of fever. If it should fortunately happen that the inflammation has been entirely subdued by the means used at the onset of the malady, the second paroxysm will be one of simple ague, at the conclusion of which the bark may be safely used, and the disease cut short. More generally, however, some degree of inflammatory action remains, which may be rekindled with considerable violence during the second paroxysm, in which case venesection must again be had recourse to, and this repetition of it will generally be successful. The moment we find that the disease is reduced to a simple ague, or that the patient, in the intervals of the paroxysms, is free from all symptoms of local inflammation, the quinine should be thrown in, at first in a moderate dose, the effects of which should be watched; for if there should still be a lurking tendency to inflammation, the medicine, by its stimulating effects, may rekindle it, and, if persevered in, occasion serious if not fatal mischief. If it be found that the first dose has no bad effect, we may proceed without fear, and repeat the remedy in large and

frequent doses, to prevent the recurrence of the paroxysm ; which is a point of some importance, because the recently inflamed organ is extremely liable to re-assume the same morbid action, which might be set up anew by the excitement of a febrile paroxysm. In those cases in which the ordinary antiphlogistic means fail to subdue the inflammation, the danger of a fatal result is considerable ; but let the practitioner be warned against the premature use of the bark, which will invariably make matters worse than they were before. In such cases I have had recourse to mercury, and generally with good effect ; when the mouth became sore, the inflammation was resolved, and in most instances the ague also was arrested, and convalescence ensued. I never tried the effect of salivation on common ague, not thinking it a justifiable procedure, merely for the sake of experiment, when we already possess a mild and efficacious remedy.

An Inquiry into the Nature and Properties of the Blood in Health and Disease. By the late Charles Turner Thackrah. Edited by Thomas G. Wright, M.D. To which is added a Biographical Memoir of Mr. Thackrah. London. 8vo. 1834. pp. 246.

(Continued from p. 324, vol. vii).

4. To the influence of the nerves—the nervous influence being considered as the source of the blood's fluidity, and its loss the cause of coagulation.

"(1.) In the preceding examination of the effects of *rest*, the veins of different animals were insulated, and it was found, that although the loss of motion failed to produce concretion, yet that the blood acquired an increased disposition to this change. In such circumstances, however, the vessels, if not partially dead, were at least so situated as not to allow the free admission of the nervous influence. On the supposition, then, of this process depending on the loss of vitality in the blood-vessels, we might conclude that concretion would have taken place in a few minutes, had the receptacle been wholly devoid of life; but from the vessels possessing a degree of vitality, the blood did not speedily nor freely coagulate. That rest alone cannot give even a disposition to concretion, seems evident from the remarks on that subject.

"(2.) In two instances (XXXIX and XL) the blood was found fluid in the hearts of oxen twenty minutes and half an hour after their slaughter, but coagulated quickly on its removal from these vessels. Vitality, in these cases, must have existed, since the

period between the apparent death of the animals and the examination of the blood was too short to admit of the extinction of the living principle; and the circumstance of fluidity being maintained as long as the blood was kept in its vital receptacles, and coagulation shortly occurring on the exposure of this fluid, strongly supports the doctrine under examination.

"(3.) In the leech which has died soon after suction, the blood is found concreted, but if it be retained in the living reptile, I have found no trace of coagulation at the end of an hour. It is probable, therefore, that the blood's fluidity is maintained by the life of its receptacle.

"(4.) In most of the cases related by Morgagni, in which the blood after death remained fluid, or but partially coagulated, the patient had died suddenly from some affection of the brain or nervous system. In such circumstances, it is known that the contraction of death does not occur, the muscles remain flaccid, and the temperature of the body is long maintained. If these effects be considered as originating from life still lingering in its tenement, we see cause, on the theory adduced, for the blood's tardiness in coagulating.

"(5.) On this subject an observation of Fontana is deserving of regard. He found, that although the coagulation of the blood out of the body was not affected by commixture with poison of a viper, yet that this substance, when injected into the veins of a living rabbit, produced instant coagulation of the circulating fluid, and the speedy death of the animal. The effect here stated could arise, I conceive, only from the shock given to the living principle resident in the heart of the vessels ; and since the preceding remark of Fontana proves the simple mixture of the poison with the blood to have no effect on the coagulating process, we must conclude that the *sudden destruction of the nervous influence induced instantaneous concretion*.

"(6.) I have proved by repeated experiments, that conglutination occurs speedily in proportion to the debility of the system. If debility affect primarily and principally the organs of sensorial power, or (to speak, perhaps, more properly) if these organs first lose their excitability, we remark, as a collateral support to the theory adduced, that in proportion as the nervous influence languishes or dies, the blood assumes a stronger disposition to coagulate.

"The faintness which occasionally ensues on venæsection has a similar and marked effect: this occurrence, if I mistake not, can arise only from the suspension of that supply which the vessels receive from the nervous system, and the consequently increased disposition of the blood to concrete.

"After thus stating the circumstances which afford plausible grounds for the a

mission of the doctrine, I proceed to more decisive evidence.

"Mr. (now Sir) Astley Cooper, to induce me to the examination of a subject, in which, from its intricacy, I despaired of success, kindly favoured me with an account of three experiments which he had made some years ago; but as the statement was merely verbal, I doubt the complete accuracy of my details."—pp. 81—83.

We subjoin a correct account of the experiments of Sir A. Cooper himself, as given in a note to the present edition of the work.

"**Exp. I.** Having carefully excluded the atmosphere from the ureter of the ox, I tied one end and put a cock upon the other. The cock was tied in the jugular vein of a dog, and being then turned, the blood rushed into it. The cock was then shut, and the blood in ten minutes was found coagulated.

"**Exp. II.** The same experiment was repeated upon the jugular vein of the ox, which was by the same means as the ureter had been introduced into the jugular vein of the dog, and the blood coagulated in ten minutes.

"**Exp. III.** Two ligatures were placed on the jugular vein of a living dog, and there left for three hours: the blood had not coagulated.

"**Exp. IV.** Two ligatures were put on the jugular vein of a living dog, leaving a space between them of three inches. Then the lower part of the vein was cut through, and suffered to hang from the wound for four hours. The upper ligature was then removed, the blood admitted into the vein, and the ligature again tightened. The blood thus admitted into the dead vein was coagulated in a quarter of an hour."—pp. 83, 84.

These experiments favour the idea that the loss of nervous influence is the cause of the blood's coagulation.

"To ascertain," says our author, "what effect the vital, or lifeless state of the vessel has upon the blood's coagulation, I made the following experiments.

"**Exp. LII.** A portion of the jugular vein of a living dog was included between two ligatures, removed from the body, and immersed in water heated to 98 deg. At the expiration of an hour the blood which it contained was found fluid.

"**Exp. LIII.** To a long portion of the jugular vein of a dog, killed two days before, were affixed brass stop-cocks, and the whole immersed for a short time in water heated to 90 deg.—100 deg. The jugular of a living dog was then laid bare, and after its puncture, one stop-cock was inserted into the opening. A small current of blood having been allowed to pass through the lifeless vessel, in order to preclude the possibility of its containing any thing but the

subject of experiment, the lower stop-cock was turned, and shortly after, the upper. The vessel, with its contents, was then immersed in the heated water, the temperature of which was maintained for a quarter of an hour. At the end of this period, the vessel being taken out and punctured, or rather cut, over a white plate, the blood was found firmly coagulated.

"These experiments evidently lead to the same conclusion as those of Mr. Cooper. *Blood confined in a vessel, which, from the time, vitality could not have deserted, did not coagulate in an hour; while that inclosed in a lifeless vein, was firmly concreted in one-fourth of that period.*"—p. 85.

After mentioning some experiments, rendered inconclusive by the difficulty of determining how long parts retain their vital irritability after the apparent death of the animal, our author gives the following, in which are compared the effects of vessels undoubtedly alive, or unequivocally dead, on the blood they contain.

Exp. LVI. "A portion of the jugular vein of a dog was included between ligatures, removed from the body, and placed on the table. On its division, at the end of twenty minutes, the blood was found fluid.

"The character and result of this experiment resemble those of many others, several of which have been already detailed, (XLVI to LI.) Suffice it, therefore, to remark, that except in one instance, I never knew blood to coagulate in a vessel recently insulated or recently removed from a living animal: and from frequent examination, I feel confident that the blood in such circumstances will be found to retain its fluidity till the expiration of, at least, half an hour.

"Some observations on blood confined in lifeless vessels will now be stated.

"**Exp. LVII.** The iliac vein of a dog, killed three or four days before, was armed with stop-cocks, and received blood from the brachial vein of a man in the mode of Experiment LIII. On examination, at the expiration of a quarter of an hour, concretion was found to be complete.

"**Exp. LVIII.** A portion of the jugular vein of a sheep killed four days before, received blood from a similar vessel in a living sheep, in the mode of LIII. At the end of a quarter of an hour, complete concretion was found to have taken place.

"These experiments, when compared with LVI. and LII., strongly support the doctrine of the blood's fluidity depending on the life of its vessels. But to make the contrast more marked and decisive, the following experiments were made.

"**Exp. LIX.** Part of the jugular vein of a small dog was secured with ligatures, and removed from the body. After re-

remaining in the temperature of about 100 deg. for half an hour, it was punctured. The blood was found perfectly fluid. A portion of the vena cava was removed, and reserved for the next day's comparative experiment.

"Exp. LX. Fifteen hours and a half after the preceding experiment, the cava taken from the animal then employed, was filled with blood (as in LIII.) from the jugular of a similar dog. On the division of the vessel at the expiration of a quarter of an hour, complete concretion had occurred.

"Thus we remark, that for half an hour blood remained fluid in a vein recently removed, while in the lifeless vein of the same animal, it was found firmly concreted in fifteen minutes. To what shall we attribute this striking fact, if not to the loss of the vessel's vitality?

"On reflecting on the experiments of this section, it occurred to me, that the brass cocks connected with the lifeless veins might afford matter of objection. To ascertain whether they had any share in inducing coagulation.

"Exp. LXI. A length of the aorta of a dog, killed the day before, received the contents of the carotid of a similar, but living animal. The elasticity of the aorta allowing the admission of the divided carotid, no extraneous apparatus was required. Preventing therefore, with my finger, the admission of air, and one of my pupils pressing the lower end of the aorta, this vessel was quickly filled. My assistant was then directed to squeeze down the blood so as to empty the vessel; care being taken to exclude the air. The aorta was then re-filled, and ligatures being applied, was immersed in water, of the temperature of 100 deg. After a quarter of an hour had elapsed, it was divided, and complete concretion found to have taken place.

"It is apparent, therefore, that the same result occurs when stop-cocks are not employed.

"After the preceding illustrations of the opposite effects which the life and death of the vessels produce on the blood, a specimen succeeds of that intermediate state in which it is probable vitality is but partially existent.

"Exp. LXII. A portion of the jugular was taken from a sheep two hours and a half after it had been slaughtered. This vessel was filled with blood (as in LIII.) from a corresponding vein in a living sheep. After having been kept in the temperature of the animal for a quarter of an hour, it was punctured. Though most of the blood was fluid, one considerable coagulum was found.

"The inference drawn from the observations of this section is obvious. Experiments, in which the greatest attention was paid to accuracy in execution, and honesty in detail, have shown that blood retained for the requisite period is found fluid in a living

vessel, partially or irregularly coagulated in a semi-living vessel, and firmly concreted in one devoid of vitality. I conclude, therefore, that *the vital or nervous influence is the source of the blood's fluidity,—and its loss, the cause of coagulation.*"

It is singular that our author should use the terms *vital* influence, and *nervous* influence assynonymous—it is taking for granted the affirmative of a much disputed question—namely, whether the sympathetic nerve is the great centre of organic life—a question which is not likely to be settled, till minute anatomy shall have afforded us more accurate information as to the real extent and connexions of the ganglionic system.

The phenomena of many diseases seem to favour the opinion that the nerves exert a strong influence on the coagulation of the blood—such phenomena, however, would, on the whole, appear to lead to a conclusion directly the reverse of that derived from physiological experiments; in diseases where there is reason to believe that the nervous power is reduced to the lowest ebb, as in the worst forms of fever, malignant cholera, &c., the blood does not coagulate. Again, in those instances where the nervous power is suddenly annihilated throughout the system, as in death by lightning, a blow on the stomach, or a large dose of hydro-cyanic acid, the same uncoagulable state of the blood is observed. After all, such observations as these go far to establish the doctrine of the *vitality* of the blood—a doctrine which the longer one thinks on, the more one feels inclined to adopt. This seems to have been partly the case with Mr. Thackrah, who in some further remarks on this subject at the end of the fourth chapter, appears less opposed than formerly to Mr. Hunter's opinion.

The intelligent editor observes.

"The concluding passages of this chapter are written on a fly-leaf in the author's copy of his former edition. They are remarkable, as showing that his arguments against the Hunterian doctrine of life in the blood were by no means convincing to himself. 'What is life?' Reason on it as we may, the question still recurs to us. Blood is certainly not a mere hydrostatic liquid, but one possessed of certain functional susceptibilities, and acted on by vital powers. If a distinction can be made between the life of blood and the life of nerves, muscles, or bones, except in relation to their differ-

ence of offices, I am not able to perceive where the line of demarcation should be drawn."—ED.

Press of matter again obliges us to suspend farther notice of this valuable work; which, however, we shall take an early opportunity of resuming.

—o—

ON DISLOCATIONS OF THE NECK AND THEIR REDUCTION.

BY E. HARRISON, M. D.

To Dr. Ryan, Editor of the London Medical and Surgical Journal.

SIR—The recent death of Lord Lisle from a fall in hunting, calls for a few remarks, especially at this season of the year, in order to prevent similar catastrophes from the same cause. "*His Lordship, it is said, pitched on his head, and it is supposed dislocated his neck, as he breathed only twice after the accident.*" Such is the brief recital of this nobleman's death. As it accords with many similar accidents from falls, I conclude that it is the true statement, and borne out by the anatomical arrangement of the parts. A few years since, Sir John Trollope, a Lincolnshire Baronet, lost his life upon the road by a fall from his horse. In neither instance does it appear that any means were attempted for their recovery, though it is upon record, that life has been preserved, or perhaps more properly restored, under similar circumstances.

I presume that every feasible scheme to recover persons in this distressing situation would at all times be favourably received by the British public. It is peculiarly applicable to the present season, when so many are liable to accidents in the perious recreations of field sports. Nor can we be insensible to the hazardous state of these momentous times, when all descriptions of people are roused into danger, and gallop about, hurry-scurry in every direction.

More than thirty years since, on taking my evening walk, I heard a loud cry for help issuing simultaneously from many mouths. I ran to the spot, and saw a man lying upon the ground. A horse was standing near: twenty voices anxiously vociferated, as I hurried along, that the rider had just fallen from his horse and broken his neck. He lay on the ground motionless and apparently quite dead. I instinctively placed my knees against his shoulders, and grasping his chin and back of the head firmly between my hands, proceeded to stretch his neck with all my strength. The patient immediately shewed signs of returning animation, by

moving his limbs, and in two or three minutes he raised himself from the ground*.

He at first rolled his eyes with a vacant stare, but speedily recovered sufficiently to remount his horse and ride home, a distance of nine miles, without sustaining any particular inconvenience from the accident. It may be said, that this man was only stupefied by the fall, and would have recovered of himself had he been left undisturbed. Whether the lifeless state to which he was apparently reduced, proceeded from vertebral subluxation, or concussion of the brain or spine, cannot be satisfactorily determined. For my own part, I then entertained the opinion that I still retain, that some of the superior cervical vertebræ, probably the first, were partially displaced, and pressed upon the spinal marrow or phrenic nerves, so as to interrupt the motion of the diaphragm, and the process of respiration. In that case, had he not been relieved from the compression, by restoring the natural arrangement of the cervical spine, death would have speedily closed the scene.

Had the suspension of life in the above case depended upon concussion of the brain or spine, the elongation of his neck would have been unavailing, and probably injurious. It was, I am convinced, a subluxation of the head and atlas, or first vertebra. The connection between these bones is easily deranged by a blow or fall, as we know from experience in brutes and man.

The sportsman kills his game by luxating the first joint of the spine, which always proves immediately fatal. This he effects by a smart stroke of the hand aimed below the occiput, and above the atlas. Or he accomplishes the disjunction by firmly grasping the back part of the animal's neck, close to the skull with his left hand, and fixing the other upon its forehead. A slight degree of force in this situation drives the condyles of the occipital bone away from the first vertebra and produces dislocation either partial or complete, according to the degree of violence employed.

Although few endeavours have been made in this country to restore animation in these distressing cases, the inhabitants of barbarous tribes do not abandon their comrades, without making strong efforts for their recovery.

Mr. Ellis, in the second volume of his *Polynesian Researches* informs us, on the authority of Mr. Baiff, "that a man fell from a tree and dislocated his neck. His companions, on perceiving it, instantly took him up. One of them placed his head between his own knees, and held it firmly, while the others, taking hold of his body, twisted the joint into its proper place." Such is the

* For a more particular account of the mode of treatment, see Dr. Harrison's *Pathological and Practical Observations on Spinal Disorders*.

statement given of the practice employed among a rude people, who, in following the dictates of nature, have often saved the lives of their fellow creatures, under circumstances deemed irremediable by the civilized nations of Europe.

The reader will perceive, that although both the above described methods have been successful in the restoration of life, they differ considerably from one another. It remains to be determined which is entitled to the preference.

The dislocation usually occurs in what is denominated a ginglymoid or hinge joint. This species of articulation admits of motion forward and backward. There is little or no lateral play. As therefore the head can only be luxated in two directions, forward or backward its position will always denote the species. In the former the chin rests upon the breast. In the latter it and the forehead are elevated.

By merely rotating the neck—the mode employed in the Friendly Islands—although the position of the head be changed, it does not follow that it had been moved in the best possible manner for the recovery of the patient.

The proper treatment is first to forcibly stretch the neck and head, in order to separate the different parts of the joint by elongating the ligaments. These, when suffered to contract again, will be disposed to restore the bones to their former or natural places. During the restoration, the head may be encouraged to move forward or backward, according to the ascertained nature of the dislocation. In order to ensure this desirable change, if fortunately a medical person were present, he might hold the upper part of the neck firmly with one hand, and assist in replacing the head with the other. This is the practice followed in other dislocations, and should be imitated in this particular species.

That the curative process is simple and easily carried into effect, even by persons ignorant of anatomy, will appear from the following case. An aged lady informed me a few days since that her mother, when young, was taking her accustomed airing, attended by a groom. The horse stumbled, and the servant, on falling to the ground, pitched upon his head. He sunk down motionless and apparently dead. The intrepid mistress seeing his alarming situation, jumped from her horse, and placing her knees against the man's shoulders, grasped his head with both hands. She then stretched his neck with all her strength. He instantly gave signs of returning animation. In a few minutes he remounted his horse and continued his ride. Nor did he suffer any injury from the hurt.

The above recited cases are the only examples that have come to my knowledge, where the attempt has been made in this country to resuscitate a human being, by

stretching the neck. As both trials were completely successful, I hope they will induce all persons near at hand to give immediate assistance on the occurrence of similar accidents, so as to ensure to sufferers the restoration of life when recovery is possible.

Holles Street, Cavendish Square.

—o—

MEDICO - BOTANICAL SOCIETY OF LONDON.

Tuesday, January 27, 1835.

THOMAS EVERIT, Esq., Professor of Chemistry, in the chair.

Dr. Ryan, the Professor of Materia Medica to the society, delivered a lecture on the distinctive characters of organic or living bodies, and inorganic bodies, or those substances not endued with life. He stated that all bodies in the universe are divided by naturalists into two classes:—1. celestial bodies; 2. sublunar or terrestrial bodies.

a. The terrestrial bodies are composed of air, earth, and the waters, with all the material beings contained in them. These are again subdivided into, 1. organic bodies; 2. inorganic bodies.

Organic bodies are composed of organs different from each other: these form systems—the circulatory, respiratory, cerebro-spinal, &c.; the functions or uses of which preserve the individuals of each class of beings, repair their losses, and perpetuate their species. These bodies are again subdivided into vegetables and animals.

Vegetables possess nutritive and generative powers, but they have very partial motion, and never locomotion or the power of moving from place to place.

Animals, on the contrary, including man, not only possess the functions of nutrition and generation, but numerous relations, and a complete power of locomotion.

Animals, in general, are guided by instinct only, and do not possess individual intelligence or mind.

Man, the especial object of our study, is, by the superiority of his organization, as well as by his reason, an attribute peculiar to his species, placed immeasurably beyond all irrational animals.

b. Inorganic bodies are fossils or minerals; fluids, and gases.

Dr. Ryan then observed, "It is not as yet determined whether imponderable substances, such as light, heat, electricity, galvanism and magnetism have a separate existence; or are only manifestations of the activity of certain ponderable bodies."

All organic and inorganic bodies, he observed, the natural connexion of their phenomena, the reciprocal equilibrium of the different laws that govern them, form *nature*, *natural economy*; and united, constitute all that infinity which is denominated the universe.

The lecturer then described the external configuration and internal aggregation of

organized beings (plants and animals), and inorganic substances, and proved the vast difference between them. He enumerated the chemical composition of both, of plants and animals, and of minerals, &c.

In animals, the constituent elements or principles are oxygen, hydrogen, carbon, and nitrogen; and in vegetables, oxygen, carbon, and hydrogen; but in a few, a small quantity of nitrogen or azote. Besides these, there are non-metallic alkaline, earthy and ponderous metals. There are also imponderable substances or principles: light, heat, electricity, and galvanism.

The professor next proceeded to institute a comparison between organic and inorganic bodies. He enumerated a host of physiologists, philosophers, and chemists in ancient and modern times, who maintained the conclusions which he drew.

Having proved the widest distinction between organic and inorganic bodies, he then described the difference between plants and animals, or organized beings. He contrasted their origin, figure, type common to species, constituent elements, unity of organization, transmission of existence and decline.

The chairman proposed to the society, that the learned professor be requested to resume the very interesting subject which he commenced this evening.

Dr. Sigmund, Dr. Negri, and Dr. James Johnson commented on a specimen of some medicine which was on the table, and which had not a place in our *Materia Medica*.

The chairman then announced that Mr. Burnett, the professor of botany, would deliver a lecture at the next meeting, Feb. 12.

Foreign Medicine.

M. Roux's Account of his Travels in Switzerland and Italy.

At the request of the members of the *Academie de Medecine* this distinguished surgeon related to them at several of their sittings, the principal points for observation in the localities through which he passed in his tour in the above named countries, with, of course, a special reference to the medical affairs.

Commencing with Switzerland, M. Roux, went at great length into the practice of M. Mayor of Lausanne, particularly as to his mode of surgical bandages. M. Mayor denies the spontaneous luxation of the femur, and attributes the shortening of the limb to an irregularity of the pelvis and the vertebral column—an opinion from which M. Roux differs, though he thinks that further researches should be made on the subject.

At Geneva a second M. Mayor made some important communication to the travellers. The first was regarding the *hydrocele of the neck of M. Maunoir*, which is a cyst of the thyroid gland; it is endemic in Switzerland, but is never observed in France. It com-

mences in one side of the gland and gradually extends to the other. When the tumour bursts or is punctured, a thick coffee-coloured fluid escapes; this is succeeded by a sanguineous effusion into the cyst, or else it is poured out: the effusion is an exudation, and not the consequence of any ruptured vessel. When the cyst is filled, the bleeding stops, in consequence of the compression of the parietes. M. Mayor, therefore, adopts the following treatment. Having emptied the cyst by means of the trochar, he stops it with agaric in order to prevent the oozing around the canula, which he also stops hermetically. The secreted blood coagulates, subsequently becomes fluid and is then allowed issue by opening the canula. The parietes of the cyst afterwards suppurate and finally adhere together; the cure is somewhat prolonged, but is certain.

M. Mayor has also paid particular attention to *inraginated necrosis*, which is more frequent in Geneva than in Paris. It is generally considered best to wait as long as possible before the operation for removal of the sequestra, which is more loose and thin as the affection is of longer standing. M. Mayor, on the contrary, thinks that the separation is complete from the commencement of the disease, and previous to the complete solidification of the new bone; he therefore is of opinion that the operation should be performed at an early date, because the instrument acts with greater facility on the non-solidified bony envelope.

Proceeding to Italy, M. Roux, examines in succession the institutions, the noted men, and the circumstances of the country. In the first are comprehended the academies, universities, and hospitals. M. R., it is necessary to remark, only visited the North of Italy, Milan, Padua, Florence, Brescia, Venice, but did not reach Rome and Naples.

With regard to the academies, M. Roux states that he was not able to visit them, and that he needed no consolation on that account.

In France there is but one university: in Italy there is one, and sometimes several, in each small state. Thus, there are seven in the Roman States; and the confusion in this particular is so great, that the doctors of the University of Sienna, for example, cannot obtain the license to practise until they have studied two years at Florence, where there is no university, but where the means of instruction are much more perfect.

Each of the universities include four faculties: that of medicine comprehends pharmacy. The principal ones are those of Pavia, made illustrious by Scarpa; of Padua, where Fabricius ab Aquapendente and Morgagni flourished; of Bologna, which is much fallen off since the late political troubles, the consequence of which was its dismemberment. It may be easily imagined that each of these universities is far below that of Paris in the number of students.

The largest number in any of them scarcely reaches four to five hundred students, whereas that of Paris includes more than three thousand, that is, more than all the Italian students together. The mode of teaching is pretty nearly the same as in France, with a few slight modifications. Eye-surgery, as a separate department, has been recently introduced from Germany, and the inspection of this special teaching only tended to confirm M. Roux in the prejudices he had long entertained against these mincings of science. It is worthy of remark, that each professor is obliged, in his lectures, to follow the plan and order laid down in the work which he uses as a textbook, a species of intellectual slavery much reprobated by the author, but in which he found a cause for exultation, since these works are, for the most part, French productions. These faculties admit three orders of practitioners, doctors of medicine, masters of surgery, and *petty* surgeons, the latter corresponding to the French *officiers de santé*.

Most of the universities are provided with magnificent collections, among which those of Bologna and Florence are particularly fine. That of Pavia is remarkable for the anatomical preparations; that of Florence for wax mouldings. Each hospital has a dissecting theatre. The students are not allowed to dissect in the first year of study, but are confined to looking on the older students. At Florence there is also a superb collection of works referring to the physical sciences; in it the instruments used by Galileo, Galilei, and Toricelli, are preserved: they are about to deposit them in a particular cabinet. Indeed, the Italians profess a religious veneration for their great men, and erect monuments and statutes to them. This enthusiasm, however, is sometimes outrageous; nor was it without a painful sensation that M. Roux beheld the head of Scarpa macerating in alcohol, among other anatomical preparations. Apropos of this subject, he relates a peculiarity found on the post mortem examination of the illustrious Italian surgeon, who, previous to his death, at eighty-four years, had lost the memory of proper names; on examining the contents of the cranium, a considerable disorganization of one of the corpora striata was found.

The organization of the hospitals in Italy presents some remarkable peculiarities. They are almost all erected in advantageous positions, and have large well ventilated wards: those for surgical diseases are separate, and are generally less carefully attended to. The great hospital of Milan probably has not an equal in Europe in regard to the architecture and extent: it contains with ease 1800 patients. These hospitals, moreover, include separate chambers for such as can afford to pay for them.

The medical hierarchy is in full vigour in the Italian hospitals: there are honorary physicians, assistants, sub-assistants, first

physicians, directors of the establishment, &c. In difficult cases the physicians meet in consultation under the presidency of the chief. It may be remarked that in this classical country of devotion, the hospitals are not deprived of the services of the *religieuses*. The union of powers in the director, who is generally a distinguished physician, whom age has rendered incapable of practice, simplifies exceedingly, and facilitates the arrangements of the hospitals.

Though Italy is far from being devoid of distinguished medical men, there are none of them whose reputation can be balanced against that of such men as Scarpa, Vacca, Bellinghieri, Paletta, and others. Of those possessing the greatest name at present is Professor Panizza of Pavia, who in anatomy at least is proceeding in the brilliant pathway of Scarpa.

M. Roux paid particular attention to the state of normal and morbid anatomy, midwifery, and surgery, towards which his tastes inclined him. Anatomy is cultivated in Italy with the greatest ardour; the country abounds with museums, with which those of France can stand no comparison. The museum of Pavia is especially remarkable, enriched as it is with the numerous undertakings of the great Scarpa. A vast number of beautiful preparations of the structure of the bones are particularly prominent. It also contains the lower limb of the individual on whom Scarpa first put in practice his mode of operating for aneurism, which, as is known, is by ligature in the inguinal space; the patient survived the operation twenty-five years. The successor of Scarpa, Panizza, has repeated Mascagni's experiments on the lymphatic system. His discoveries on this head have been more particularly interesting with regard to the lymphatics of the generative organs. Nor are his researches into the nervous system less important, one of the preparations shewing with the greatest exactness the connection of the nerves of the great sympathetic with the anterior branches of the spinal nerves. But a still more important result of his injections is the proof that the serous membranes are eminently vascular—a fact denied by many physiologists and anatomists, who look upon those membranes as inorganic, as a kind of epidermis placed over the vascular tissues beneath.

At Bologna, M. Roux was struck with the preparation of a head of immense proportions that had belonged to a body of ordinary size: the individual had exhibited nothing unnatural in his intellectual faculties.

At Florence, in the cabinet arranged by M. Zanetti, M. Roux saw the following preparations. 1. A skull perforated by a dagger, which caused the inner table to project an inch into the cerebral cavity, without however inducing any particular cerebral lesion; the person survived a long time with the steel fixed in the bone. 2. Two

pieces, which shewed to demonstration the indentation of the cranium, without fracture. 3. The womb and pelvis of a woman who survived one Cæsarean operation, but died after the second. 4. The head of a hydrocephalic child, containing thirty-two pounds of water. 5. A radius, the diaphysis of which is covered with a bloody fungous tumour which had been mistaken, in life, for an aneurism.

In all the Italian faculties there are obstetric clinical courses. At Milan, M. Roux saw two placentas continuous with each other: it had occurred in a twin case, and is a fact, the existence of which has been frequently denied; it justifies the practice advised by M. Capuron of tying the cord of the first born child. The director of the maternity of Milan, M. Milly, told M. Roux that out of several Cæsarean operations he had been twice successful. There is in the same place a very fine collection of ill-shaped pelvises. M. Milly observed, that when the deformity of a pelvis consists in an obliquity of one side coinciding with a narrowing of the same side, there is always a complete ossification of the corresponding sacro-iliac symphysis; so that symphyseotomy would prove useless in such a case.

With regard to surgery, the Italians care little for French or other doctrines; those of Scarpa are exclusively predominant. Lithotomy is scarcely known; M. Roux only met one surgeon that had performed it twice. But what is most astonishing is, that the operation for cataract by extraction is totally unknown in Italy. At Florence M. Andrini shewed M. R. an individual in whom he had cured an aneurism of the crural artery by Valsalva's method, the general debility not allowing of his operating. At Venice he saw a man who had fallen from a high scaffolding with the back of his neck against a stone two square inches thick, which divided the skin and muscles and forced on to the vertebræ, without fracturing the bones and causing mischief of the brain or cord; the man was perfectly recovered. M. R. also saw a leg that had separated by sphacelus, after compound fracture; likewise, at Milan, a varicose aneurism of the bend of the arm, cured by tying the brachial artery above it. M. Roux succeeded in reducing a complete dislocation of the fore arm, that had continued for five months. It had every appearance of being ankylosed, but, having been successful in similar cases before, he attempted and effected the reduction; the arm was restored to its functions.

Microscopical Observations on the Organization of Animals.

M. Ehrenberg, of Berlin, in a late work, maintains that it is impossible, with our present means of observation, to demonstrate the existence of a primitive animal matter, as mentioned by authors. In his examination of infusoria, and even of the most simple of them, he found so complicated an organiza-

tion, as to preclude the idea of a spontaneous generation. The learned author also makes known three new families, 35 genera, and 135 species. He adds some new facts to those already ascertained concerning the organization of infusoria. He has discovered masticatory organs in the *infusoria polygastrica*: these organs had been previously only noticed in the *ratifera*. In the *polygastrica*, he also remarked two globular radiated organs, which he considers to be the male generative parts. He has also remarked organs in the *ratifera*, which he looks upon as the respiratory; and he moreover asserts that a nervous system is to be found in all the *infusoria*.—*Archives Generales*.

Researches into the Crustacea, &c., by Dr. M. Edwards.

In a letter addressed to the Académie des Sciences, Dr. Milne Edwards, gives some of the results of his voyage to the coast of Barbary. His principal object was to make researches into the crustacea, annelides and zoophyta, an object in which he does not appear to have failed.

I have ascertained, he says, that polypi, living in one collected mass, have generally much more close connexion with each other than is commonly believed. Far from being merely conglomerated individuals, they possess, in the majority of instances, a perfect individuality. They are a kind of sprout, which, at the same time that they are capable of living in an isolated state, have only a portion of their organs in common, and which grow on certain parts of the trunk and branches of the polypus stalk, without becoming altogether distinct from their originals. M. Edwards has discovered the means by which nutritive matters, taken by one of these polypi, may generally be useful to the whole group; and he has ascertained the parts of their body that are endowed with the vegetative faculty; on which fact, the general disposition of the polypi stalk depends. He has also inquired into the mode of formation of the ovula, by which these animals are reproduced, and their race propagated. This double mode of reproduction, (by sprouts and ovula) seems to exist both in the zoophyta and the complex ascidia.

M. Edwards' observations promise to throw some light on the formation of the solid parts of the polypi-stalk: they will also bring forward some new genera.—*Gaz. Med. Janvier 17th*.

Verminalion a cause of Mania.

M. Ferrus lately exhibited a *tania* to the Académie de Médecine, which he had purged from a maniac. Immediately on its expulsion the insanity disappeared. Several members recited instances in which the insanity of hysterical persons has been cured by the evacuation of the *tania* and other intestinal worms.

The London Medical

AND

Surgical Journal.

Saturday, January 31st, 1835.

EDIFYING PARALLEL.

WE recommend the following extracts from M. Sabatier's recent "History of the Faculty of Medicine of Paris" to the perusal of the exclusive gentry of the Faculty of Medicine of London, to whom we would remark—

Mutato nomine de te fabula narratur.

"One of the most pressing orders given to the young doctors, was to engage in nothing but their own art, and not to enter upon any occupation alien to it. Unfortunately surgery (*add midwifery*) was comprehended in these profane occupations, which lowered the dignity of the physician, a calling the utility of which they estimated from the time when it was part of the barber's art, but which it was folly to reject when this rival science became as high in Paris (*London*) as medicine.

Disputes kept hot by party spirit against the Montpellier physicians (*Edinburgh graduates*), and influencing even scientific and practical questions, presented so many subjects for laughter to the common enemy of all the Faculties, Moliere (*Wakley*). Some Montpellier physicians (*Edinb. grad.*) having settled in Paris, the Faculty claimed *the privilege of their members alone to practise in the capital*. Hence arose law cases, pleadings, paper wars, and abusive language. The newly-arrived physicians employed tartar emetic: the Faculty proscribed it. *The Parliament was obliged to sit in judgment on their disputes*. The association of new physicians resisted for twenty years the actions, and even the verdicts given against them. At length the Faculty appealed to the royal authority itself, and Louis XIV. re-instated them in their privileges.

"Happy had the Faculty been if their long delayed and dearly bought victory had dissuaded them from fresh disputes! *But all privilege has a tendency to aggrandizement, and every monopoly is in its nature intolerant!* The Faculty rejected opium, mercury, and bark, as it had rejected tartar emetic, because they came from another source

than themselves. *It was a kind of inquisition erected in medicine, which aimed at the imposition of its dogmata, the foremost of which was the recognition of its infallibility.* And when at length, spite of all their efforts, these remedies were admitted by royal decree into the *Materia Medica*, Guy-Patin (*H. Halford*), that valiant champion of the privileges of his order, was nearly dying of vexation. *Meantime the 18th century was dawning, a century fatal to many privileges, and particularly to those of the Faculty.*"

But Maréchal and Lapeyronie roused the spirit of surgery:—

"In 1774 the first stone of the College of Surgery was laid, which is now the *Ecole de Medecine*; and by a singular coincidence, in the very year when the Surgeons took possession of their Hall, the Faculty was obliged to quit its premises in the Rue de la Bucherie, which *three centuries of dust and dilapidation threatened with ruin—the mournful forerunner of the fall of the Institution itself!!*"

How like our kindly, but short-sighted friends in Pall Mall, is all this! The rejection of opium, tartar emetic, &c., is a fit type of the rejection of all reforms, however wholesome and satisfactory. The Parliament judged of the Parisian as the Parliament will judge of the London Faculty: let them look to this: nor let them hope from any appeal to the royal authority—these are not the days for the reckless use of the latter, nor for the corrupt judgment of the former. Our appeal is to the common sense and sense of common justice of the community, against the glaring nonsense and flagrant injustice comprised in the privileges of our Faculty. How humiliating is it to think that both should have been opposed and exposed by the French medical reformers so far back as 1680, while in this our land the same nonsense—if different, only more outrageous—and the same injustice—but greater in degree by comparison with the enlightened age—are allowed still to flourish, and lord it over the brains and feelings of highly educated and philosophical men!

The French Faculty quitted their premises when, like their privileges, they were about to fall about their ears! Picture them collecting their musty charters and moth-eaten tomes, and marching with bag and baggage to their new quarters, consoled, no doubt, in this novel species of ejection, with the hope that their removal to a more modern edifice would be taken as an image of renewed vigour in their body corporate! Picture their lugubrious countenances and "long-drawn windy suspirations," on finding themselves shivering with dignified frigidity in the unfrequented halls of their new College, tottering under the weight of mortgages entailed by their removal, and listening with anxious ears to the popular voice from without, expressed now by laughter, that pierced the very stone walls and rang through the echoing chambers; now by groans of contempt, whose deep-toned resonance was but poorly adapted to soothe their perturbed spirits! Picture all this of a past Faculty, and you have a tableau vivant of a present one—of a set of living creatures to be found in Pall Mall. There is something in this like a metempsychosis, or transmigration of souls—the souls of the old Faculty of Medicine of Paris have surely passed into the bodies of our existent friends of the above-mentioned address: the same addled pates, the same dignified stolidity, the same troubles and "pressure from without," the same emigrations with the same motives, fall to the lot of both! Nay, the very President of the "*ancienne Faculté*," the very Guy-Patin, "that valiant champion of the privileges of his order," lives again in our Sir Henry! And had M. Sabatier deigned to give us the personal appearances and history of the worthies whose acts and misfortunes as a corporation he so well relates, doubtlessly we should have found many of them "*redevivi*" in the elegant faces and forms, the tall and lordly statures, the expanded smiling

countenances of our modern fellows, together with all that *liberal* character of mind which distinguishes the members of *our* modern Faculty.

Why do not these persons read? Why do they not look to the history of bodies like their own, and gather instruction from them? They would find, for instance, in M. Sabatier's history, that the revolting stupidity and arrogance of this Parisian Faculty at length brought together the enlightened part of the profession, for the purposes of defence; that from acting on the defensive they became the assailants, and at length formed themselves into a formidable body, patronized by the reigning powers, and denominated the "*Société Royale de Médecine*," of which the justly celebrated Vicq. d'Azyr was President. They would find, that though the privileges of the Faculty were not abrogated, yet, as they existed *in spite* of the spirit of the age, they passed into a dead letter, while the newly formed corporation daily increased in the esteem of the thinking and enlightened. But, lest they should doubt this, we will quote the words of the history itself.

"The Royal Society of Medicine, more youthful, more vigorous, keeping pace with the ideas of the age, had no difficulty in outstripping a decrepid institution in which the course of study and lectures was still continued according to ancient statutes. In this manner the number of pupils diminished; the lectures were deserted; and when in the midst of the political whirlwind of 1792, a law declared that the Faculties were abolished, that of Paris left no regrets—the law had only annihilated a corpse."

Some politicians say that a whirlwind is approaching our institutions: we hope it will only blow about Pall Mall East. But the historian asks—

"How happened it that this Faculty, once so powerful and so celebrated, came to be reduced to a state of exhaustion by which it would shortly have expired, even had no revolution crushed it?"

"Oh!" cry the Fellows, "they did not prosecute enough: they should have made more gagging bye-laws, and acted upon them, and thus tamed the spirit of the age to themselves, instead of yielding to it. Because they neglected this they fell." We apprehend, however, that M. Sabatier gives a more rational answer to his own question: it is this, and should be engraved on the memory of the "Fellows."

"It was because, in institutions as in men, movement is the condition of life: we must be progressing if we would not remain and die."

Messieurs the Fellows! "read, mark, learn, and inwardly digest" this physiological maxim.

—o—

MEETING AT THE ROYAL COLLEGE OF PHYSICIANS.

THE first meeting of the Royal College of Physicians, which included a heterogeneous class of visitors, took place on Monday last, January 26th.

SIR HENRY HALFORD in the Chair.

The celebrated Baronet had had most of the Cabinet Ministers and genuine Tories to dine with him, and afterwards to accompany him to Pall Mall East. Sir Robert Peel, the Lord Chancellor, Lord Abinger, Chief Justice Tindall, the Bishop of London, and many of the rankest Tories were present. The library of the College was crowded to excess; about 700 persons were present, most of whom were anxious to have a look at the lions of the evening.

The renowned Chairman and President of the College read a paper of his own, on the diseases of eminent modern characters, giving an account of the diseases of all the English monarchs, from Henry VIII. to George III.—the case of our late revered master, King George IV., was passed by, lest the present monarch should feel pain by allusion to his predecessor. The cases of Dryden, Addison, Swift, and the

Duke of Gloucester, made up the rear, though all the newspapers placed the names of these distinguished individuals in a different order.

The letter written by Geo. III., of which Sir Henry was the bearer, to the Princess Amelia, who died in two days afterwards, "was an inheritance of example" — an inheritance of example left to posterity. Shakespeare, of collegiate medical authority, was freely quoted, and a few Latin quotations, read most pedantically, astounded some of the auditory. Upon the whole, the meeting was inimitably got up: the histories of the diseases of several kings, and the medical treatment detailed in plain language, must have interested the non-professional nobility, judges, &c. It is but justice to state, that though we despise the antiquated and bad policy of the President and Fellows of the College of Physicians in their official capacity—and many of them are our personal friends—we are bound to admit, that when Sir Henry Halford is conveyed to the tomb of his ancestors, we know no one of his order (medical) who is qualified to succeed him as President of the College, or any one who could have Whigs or Tories, it matters not which, so much under controul. We expected every moment an eulogium on the present Ministry, but our contrast of Sir Henry's fulsome adulation of the Grey after the Wellington Administration, produced the desired effect.

—o—

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Operations—Submucous Erectile Tumours—Division of Palmar Fascia for contracted Fingers.

A YOUTH, aged 18 years, was brought into the theatre, having one of those tumours, of considerable size, generally known by the name of *nævi materni*, which was situated at the inner angle of the mouth. It was congenital, but had of late, years very much and rapidly increased in size. The

tumour is scarcely perceptible on the exterior of the face, its existence being only distinguishable by the blue livid colour to be perceived through the skin at that point. On everting the angle of the mouth, a large irregular tumour is brought into view, of about the size and somewhat of the form of a poached egg, which implicates the sub-mucous cellular tissue of the gums. It would hence, from this description appear, that the tumour ought to be regarded as an instance of the accidental erectile tissue being developed in the sub-mucous, rather than in the subcutaneous cellular tissue. The tumour having these extensive attachments, Mr. Hawkins was dissuaded from attempting its extirpation by the knife or ligature, and hence adopted the plan of dividing the tumour extensively, with the view of exciting the process of adhesive inflammation. He took a very small and narrow knife, (somewhat like a cataract knife) and introducing it through the integuments, about two inches behind the angle of the mouth, passed it into the very centre of the tumour, which he divided very extensively, by passing the knife backwards and forwards in almost every possible direction. By this means the object was effected, without making any external wound, beyond the small puncture necessary to admit the knife, nor did any hæmorrhage occur.

After the operation, Mr. Hawkins made a few remarks on the various modes of treating this variety of tumours; by excision, by ligature, by vaccination, by the seton, by caustics, and by the mode in this instance adopted—division.

A patient was now brought into the theatre, having a contraction of the little and ring fingers of the right hand upon the palm, from that affection of the palmar fascia, for the precise knowledge of the nature of which, we are principally indebted to the dissections of the Baron Dupuytren, though it appears that Sir A. Cooper had previously identified the disease. Mr. Hawkins proceeded to perform the operation of dividing the fascia, as practised by Dupuytren. He commenced by making a transverse incision about an inch in length, through the integuments of the palm, corresponding to the centre of the last metacarpal bone. By this means the outer strip of the fasciæ, passing to the little finger, was exposed, and was now freely divided. A considerable degree of the abnormal state of flexion was thus removed, but as some of it still remained, another semi-circular incision was now made at the base of the little finger; and the two diverging strips of fasciæ divided, just as they are about to be implanted into the lateral ligament. In this way, the flexion of the little finger was almost entirely renewed, and a corresponding incision of the integument, and division of the internal strip of fascia, passing to the ring finger was found to be sufficient to ob-

viate that of the finger in question. It was, however, thought advisable to make a longitudinal incision through the skin, so as to divide the integument; this was done, and it was found thickened to the extent of nearly half an inch. Strips of lint were now placed in the incisions, and ordinary dressings were applied. The hand was directed to be kept constantly extended upon a splint, by means of a roller; and Mr. Hawkins hopes that by maintaining this position until cicatrization shall have been established, that a cure will be effected.

Addition to the Report of the Rhinoplastic Operation, performed by Mr. Keate.

20th. Since the operation was performed, a slight erysipelatous inflammation has attacked the integuments of the face, including the flap. Adhesion, however, appears to be taking place to a considerable extent. To-day Mr. Keate removed the ligatures, in doing which, a slight prick or two of the scissors shewed that the circulation in the flap was vigorous. On touching the skin of the flap, the sensation is referred by the patient to the part of the forehead over the left eyebrow, from which the flap was taken. An evaporating lotion of rectified spirits of camphor mixture is kept applied to the face, and he is taking saline draughts, with tartarized antimony. He appears to be in good health, and complains of being starved, only being allowed broth diet.

24. The case is going on very favourably: the erysipelatous inflammation has almost entirely subsided, and adhesion has taken place throughout the circumference, with the exception of a spot or two at the points of reflexion of the flap. The man's general health is very good.

—o—

WESTMINSTER HOSPITAL.

Venereal Phagedæna of the Upper Palpebra, with Clinical remarks by Mr. Guthrie.

ELIZABETH HOLLIS, aged 21, presented herself amongst the out-patients, on January 5th, with extensive inflammation and ulceration of the left upper eyelid. She is of a pale complexion, and of a leucophlegmatic habit; and states that she obtains her livelihood by working in the gardens at Brentford. She strenuously denies ever having had any syphilitic disease, to which source, notwithstanding, Mr. Thomson attributes the affection. About a fortnight ago, she states, that she first noticed a little pimple or two, about the size of pin's heads, upon the margin of the eyelid; that these gave a little pain, became red and enlarged; that with this, the conjunctiva became injected, (or to use her own expression, "the eye became blood-shot"); and that these

symptoms have gradually increased until they reached their present intensity. At this time the eyelid is in a highly inflamed state, being extensively swollen, and of a dusky-red colour; presenting on its ciliary margin several spots of creeping ulceration of a dirty-yellowish colour, and which are principally seated near the external canthus; these secrete an unhealthy looking pus. Two of these patches are very large, and extend in the form of deep and broad fissures, into the eyelid, having involved much of the actual substance of the tarsal cartilage. The inflammation of the lid has most of the characters of œdematous erysipelas, and extends upwards as far as the supercilium. The conjunctiva is highly injected, but there is no chemosis; the eyeball is suffused with an excessive secretion of hot and acrid tears. With these symptoms is combined excessively acute pain in the organ, and intolerance of light. The internal structures are not at present implicated.

The bowels have been constipated since Thursday; she has no appetite; the tongue is slightly furred; pulse 60, and feeble. She complains of having been troubled with shivering, and pain in the limbs.

7th. She was received into the hospital yesterday, since which she has admitted having had venereal sores on the labia and internal organs during the last five weeks. Mr. Thomson has therefore decided to treat her case as one of a secondary symptoms, and has directed her to take the following pills:—

Rx. Hydrarg. submur., gr. ss,
Opil Pul. gr. ½ M. ft. pil.

Secundâ horâ sumendâ.

He has also directed the application of the celebrated unguentum nigrum, vel argenti nitratis, of Mr. Guthrie. The bowels have not yet been relieved.

10th. The eye remains much the same; she complains still of excessive pain; there is no ptyalism. The ointment is changed for one of calomel, and the quantity of opium in the pills is doubled; she continues taking them every second hour.

Mr. Guthrie, in the perambulatory clinique, observed that the case was a highly interesting one, and of very unusual occurrence; but by a singular coincidence, there is another similar case at the present time at the Ophthalmic Hospital. In about 24,000 cases of eye-disease which he had seen, he did not suppose that he had met with more than nine or ten such cases. He considered it to be of decidedly constitutional origin.

12th. The pain and redness of the eyelid all evidently diminished. She complains of a metallic taste, and of soreness of the mouth and throat, but there is no increased action of the salivary glands as yet.

14th. The soreness of the mouth and throat is increased, though there is but little ptyalism. The local affection is, however,

much benefitted, the conjunctival inflammation has entirely disappeared, that of the palpebræ is also much relieved; the organ is much more tolerant of light, and the pain likewise much diminished.

16th. Salivation to a slight extent is established; she continues to improve, but complains of pain in the head.

19th. The ptyalism is more severe, but not even now profuse, though she continues the calomel: since last report the eye has continued to improve; the progress of the ulceration is entirely checked, and the ulcers have lost their corroding and unhealthy character, and are now rapidly filling up with healthy granulations; cicatrization is also taking place at their margins. The surrounding inflammation of the palpebræ has also nearly disappeared, a mere chronic sort of tumefaction alone remaining. Indeed it is surprising to observe the rapid and decided amendment which has taken place in so short a time.

20th. Mr. Guthrie, to-day, gave a clinical lecture on the two cases which are now under his care, the one at the Ophthalmic Hospital, and the other, which forms the subject of the present report. He observed, that he did not regard the ulcers which formed upon the eye-lids in these cases, as primary sores, nor yet even of the first order of secondary symptoms: they appeared usually after the cutaneous eruption and sore-throat; they commenced generally in the form of a little pimple or sty, which he was disposed to consider a mere common hard column, which from the constitutional taint subsequently takes on a syphilitic character. In a short time the sty becomes a rapidly corroding ulcer of a yellowish-white colour, which would rapidly eat away a great portion of the eyelid unless quickly placed under treatment. This characteristic ulcer is surrounded by considerable tumefaction and inflammation. He generally observed it to attack the outer rather than the inner skin of the eyelid, and also, as in these cases, to affect that part adjoining the inner, in preference to the outer canthus of the eye. The affection was generally attended with a peculiar cast of countenance, highly characteristic of the existence of the syphilitic virus in the system, and which would usually enable the practitioner to distinguish it from a carcinomatous and other forms of ulceration of the palpebra sometimes met with, but which possessed their own distinctive characters. In both these cases the patients had at first resolutely denied labouring under syphilis, but in both cases, on more close inquiry, the suspicions entertained from the character of the inflammation were found to be well founded. They have both been treated in the same manner, with calomel and opium, and have both yielded with surprising facility upon getting the system under the influence of mercury.

Mr. Guthrie entered somewhat into the detail of the history of the case which had occurred at the Ophthalmic Hospital, but as it is almost a direct counterpart of that now reported, we need not introduce it.

24th. The eye is now nearly well.

—o—

NEW PHARMACEUTICAL PREPARATIONS.

—

It is well known that the infusions and tinctures prepared according to the pharmacopœias are often unchemical, and, in general, very liable to decomposition. The following preparations, on account of the advantages which they afford both to prescribers and compounders of medicine, are respectfully submitted to the notice of medical practitioners, by J. Bass, Pharmaceutical Chemist, Hatton Garden.

Essence of Senna.—One part of the essence of senna mixed with seven parts of water, will produce infusion of senna in every respect similar to that prepared according to the direction of the London Pharmacopœia. It will entirely obviate the waste, trouble, and delay which attend the ordinary process of preparing that infusion, and will also enable the practitioner, in exhibiting it, to increase the strength without adding to the bulk of the dose.

The process by which this essence is obtained, has been arranged expressly to secure the purgative principle of senna from the deterioration inevitably occasioned by exposure to the air and to high temperatures.

(From the account of Bouillion Lagrange, it appears that the active medicinal principle of senna, when obtained in a separate and diluted form, combines rapidly with the oxygen of the atmosphere, forming an insoluble compound, which is entirely devoid of efficacy. By the application of heat, this injurious action is accelerated, and it is therefore obvious that any attempt to obtain a concentrated form of infusion of senna, by the means usually employed for obtaining vegetable extracts, must prove a complete failure. Colladon, in his elaborate work on senna, states that a watery infusion of the leaves, exposed to ordinary evaporation, is diminished three fourths in cathartic power. This explanation the proprietor of the *Essence of Senna* considers highly important, many imitations having been brought forward, which are obviously results of a common heat applied to senna, a most destructive process.)

In proof that this object has been accomplished, the proprietor begs to refer to the public recommendations inserted in former editions of his paper, as well as to numerous private testimonials from practitioners of eminence.

Concentrated Infusions of Chamolile, Orange Peel, Calumba, Cloves, Cascarella,

Cusparia, Gentian, Quassia, Rhubarb, Roses, Simarouba.

The infusions ordered in the London Pharmacopœia are principally watery solutions of the more delicate volatile and extractive parts of certain vegetable matters; and the process directed, that of maceration in water, at a temperature diminishing from the boiling point, is obviously intended to preserve those parts which continued coction would injure or dissipate, as well as to prevent the solution which it might effect, of such as would be useless or disadvantageous. It is, however, well known, that the strict and uniform observance of the directions given in the Pharmacopœia, simple as it may appear in theory, is practically difficult, if not impossible. Amidst the constantly recurring urgencies of medical practice, infusions are often unavoidably produced in a very defective state, from the impossibility of allowing them time for sufficient impregnation, and of attending properly to the comminution of the material infused, as well as to the purity, temperature, and uniform action of the water. And, apart from the labour and delay necessarily incident to the common process of making infusions, a considerable loss is frequently incurred, in warm weather particularly, from the rapid decomposition of that portion which is not immediately wanted.

The concentrated infusions above enumerated, which merely require to be diluted in the proportion of one part to seven of water, will completely relieve compounders of medicine from these inconveniences, by enabling them to produce, at a moment's notice, and without trouble, infusions of *full and uniform strength*.

Concentrated Decoction of Sarsaparilla, simple and compound.—The concentrated decoction of sarsaparilla will remove the necessity for a very tedious and complicated process. The means employed to render the preparation a perfect educt from the best variety of sarsaparilla, will it is hoped, preclude a recurrence of the disappointments which have sometimes accompanied the exhibition of that medicine, and which probably have been attributable, in most instances, either to inferior quality of the root, or to mismanagement in the treatment of it.

Independent of the value of the concentrated decoction of sarsaparilla in facilitating the business of the Dispensary, it is particularly adapted to the use of persons going abroad, or who may be otherwise so situated as to be unable to obtain the ordinary decoction.

One part of the concentrated decoction is to be mixed with seven parts of water, to form the decoction of sarsaparilla of the London Pharmacopœia.

Essence of Cubebs.—The form of powder, in which cubebs are usually given, has been frequently found objectionable; first, be-

cause, from exposure to the air, the powder, however carefully prepared and kept, loses in a greater or less degree the volatile parts upon which its effects are supposed to depend; and, secondly, because it is in some cases impossible to give it to the requisite extent, on account of the mechanical irritation which it produces.

The essence now recommended contains the whole of the essential oil and resinous extractive matter of cubebs. It may be depended upon for perfect uniformity of strength, and, without being liable to the ordinary objections against the cubebs in substance, it will produce the specific action for which they have been so distinguished. One drachm of the essence is equal in strength to two drachms of freshly powdered cubebs, and it may be given either in water or milk, or in the form of an emulsion, to which it is well adapted, with yolk of egg or mucilage of gum arabic, and distilled water.

Concentrated Essence of Camphor.—This essence being miscible with water, is extremely convenient for making camphor julep, and for combining camphor with fluid forms of medicine. Thirty drops by measure, added to two ounces of distilled water, will form camphor julep of the usual strength.

Essence of the Ergot of Rye.—Four fluid drachms of this preparation are equivalent to one drachm by weight of the powdered ergot.

Essential Oil of Copaiba.—Dose—From fifteen to thirty drops.

Corigeen, or Irish Pearl Moss.—This valuable moss, commonly known by the above names, has long been highly esteemed by the peasants on the western coast of Ireland as a dietetic remedy for various diseases; more especially for consumption, dysentery, rickets, scrofula, and affections of the kidneys and bladder. Dissolved by being boiled in water, it forms a thick jelly, more pure and agreeable than that produced from many other vegetables, and the jelly made from it is found to agree better with the stomach than any prepared from animal substances. A decoction of the moss, made by boiling half an ounce in a pint and a half of water, or milk, until reduced to a pint, is recommended as food for children affected with scrofulous or ricketty diseases, for such as are delicate and weakly, and for infants brought up by hand, or after weaning. As an article of diet for invalids generally, it is equal if not superior to arrow root, sago, and tapioca, being highly nutritious, bland, and easy of digestion.

The Corigeen appears to possess qualities similar to the Iceland moss, but without its unpleasant flavour, and the quantity of nutritious jelly it produces, is truly surprising. The prevalence of consumptive diseases in this moist climate, which often arises from neglected colds, renders this simple restorative of peculiar interest; it is, therefore, necessary to take some healing antidote, and

the Corigeen appears to be a valuable auxiliary.

Directions for using the Moss medicinally.—Steep a quarter of an ounce of this moss in cold water for a few minutes, then withdraw it (shaking the water out of each sprig) and boil it in a quart of new or unskimmed milk until it attains the consistence of warm jelly—strain and sweeten it to the taste with white sugar or honey, or, if convenient, with candied Eryngo root; should milk disagree with the stomach, the same proportion of water may be used instead. The decoction made with milk is recommended for breakfast to consumptive patients; and that with water will be found a most agreeable kind of nourishment, taken at intervals during the day, the flavour being varied with lemon juice or peel, Seville orange juice, cinnamon, or wine of any sort most congenial to the palate.

The Decoction in water is also taken for the relief of cough, at any time in the course of the day, when it is troublesome; and it is, for this purpose, simply sweetened with honey.

In dysentery, the decoction, either in milk or water, may be administered with equal advantage, and in addition to the sweetening matter (if a tea-spoonfull of the tincture of rhatany be mixed with each cupful, a tone will thereby be given to the intestines, at the same time that nourishment will be conveyed to the system, and irritation prevented: a large tea-cupful of the decoction may be taken three or four times a day.

As a pleasant strengthening food, boiled with milk, and strained, with the addition of a little sugar, it is unrivalled for infants. Delicate persons take it in this way for breakfast and supper with the happiest effects.

INTELLIGENCE,

Medical, Surgical and Scientific.

—

Military Orphan Fund, Bengal.—The members of the Bengal Medical Board, and Superintending Surgeons, who have had the rank of Colonel and Lieutenant-Colonel, assigned by the Honourable Court of Directors without however, any attendant advantage being granted to them in regard to furlough, retiring pension, or claims to prize-money, have lately been called upon by the general management of the Military Orphan Fund to pay an increased rate of subscription to the fund, in proportion to their advanced rank. The members of the Medical Board and Superintendant Surgeons considering this demand upon them both as frivolous and vexatious, memorialized government upon the subject, in answer to which memorial, government have decided that the general management are correct in calling for such additional charge, and have

sanctioned the deduction from the members of the Medical Board and Superintendent Surgeons of the rates of subscription laid down in the Military Orphan Fund regulations, for the corresponding ranks of Colonel and Lieutenant-Colonel.

Medals of the Royal Society.—In order to perform our part in giving publicity to the determinations of the council of the Royal Society, with respect to the Royal Medals, we extract the following notice from the second part of the Philosophical Transactions for 1834, which has just appeared—

“His Majesty King William the Fourth, in restoring the foundation of the Royal Medals, graciously commanded a letter, of which the following is an extract, to be addressed to the Royal Society, through his Royal Highness the Duke of Sussex, K.G., President.

“Windsor Castle, March 25th, 1833.

“It is his Majesty's wish, First, that the two Gold Medals, value of Fifty Guineas, shall henceforth be awarded on the day of the anniversary meeting of the Royal Society, on each ensuing year, for the most important discoveries in any one principal subject or branch of knowledge.

“Secondly, that the subject matter of inquiry shall be previously settled, and propounded by the Council of the Royal Society, three years preceding the day of such award.

“Thirdly, that literary men of all nations shall be invited to afford the aid of their talents and research; and

“Fourthly, that for the ensuing three successive years, the said two medals shall be awarded to such important discoveries or series of investigations, as shall be sufficiently established or completed to the satisfaction of the Council, within the last five years of the day of award, for the years 1834 and 1835, including the present year, and for which the author shall not have previously received an honorary reward.”

(Signed) “H. TAYLOR”.

The Council propose to give one of the Royal Medals in the year 1836, to the most important unpublished paper on Astronomy, communicated to the Royal Society for insertion, in their Transactions, after the present date, and prior to the month of June in the year 1836.

The Council also propose to give one of the Royal Medals in the year 1836, to the most important unpublished paper on Animal Physiology, communicated to the Royal Society for insertion in their Transactions, as above.

The Council also propose to give one of the Royal Medals in the year 1837, to the most important unpublished paper on Physics, communicated to the Royal Society for insertion in their Transactions, after the present date, and prior to the month of June 1837.

The Council also propose to give one of the Royal Medals in the year 1837, to the author of the best paper to be entitled Contributions towards a system of Geological Chronology, founded on an examination of fossil remains, and their attendant phenomena, such paper to be communicated to the Royal Society for insertion in their Transactions after the present date, and prior to the month of June in the year 1837.

M. Dupuytren's Will.—The amount of legacies which M. Dupuytren intends to make is said to be equal to 500,000 francs. M. Dupuytren's health, although not recovered, causes no fear of a speedy realization of the dispositions of this remarkable will. It is understood that a new chair will be founded in the Ecole de Medecine. It is also probable that one item will be for the erection of a public fountain; nothing more is known of it.

[This is a very fair specimen of coolness; such comments must be exceedingly pleasant to the dying man.]

—

Cholera at Marseilles.—According to a learned physician of Marseilles, the cholera still continues there in isolated cases. The number of sick has never exceeded five and of deaths three per diem. The disease has passed from the better to the poorer classes. From the 11th December to the 7th January there were 43 cases and 27 deaths. The first 16 patients all died; the seventeenth, the wife of a physician, after being for several hours in the blue stage with extinguished pulse and icy coldness of the surface, was saved by friction of six ounces of strong mercurial ointment—a treatment which, combined with opium and ice internally, the reporter strongly recommends. It causes no salivation.

—

Poisoning by Sausages.—It appears that cases of poisoning by bad sausages and puddings are pretty frequent in certain districts of Wertemberg, in the neighbourhood of the Black Forest. In the Heidelberg Chemical Annals there is a great number of such cases related by Dr. Bodenmüller, who observed them in the winter and spring of 1834. The symptoms were most alarming, and several individuals died; the pudding they had eaten was chiefly composed of liver, and had become sour. The sausages that had caused poisoning were clotted and reduced to a kind of pap in the centre, were exceedingly bitter and rancid in taste, and cheesy in smell. Vomiting should be immediately induced, or if already effected, a purgative draughts of glauber salt, and clysters of vinegar and soap should be had recourse to.

[It is wonderful that no such cases occur in London: the sausages from the Continent remain exposed to influences, and for a time

quite sufficient, we should imagine, to induce the changes in them which render them poisonous.]

Effects of the Atmosphere at great Altitude.

On 16th December, 1831, M. Boussingault mounted the Chimborazo as high as 6,006 metres—the greatest elevation yet attained on land. In his memoir on this subject, M. B. gives it as his opinion, that it is possible for men to become accustomed to rarefied air. At an elevation nearly equal to that attained by De Saussure on Mont-Blanc, when he had scarcely strength to employ his instruments, young women in America pass whole nights in dancing. A celebrated battle in the war of independence, the battle of Pinchincha, was fought at a height very little below that of Mount Rosa. M. de Saussure's guides assured him that they had seen the stars at noonday; but M. Boussingault, who went much higher in America, than Saussure could have reached in the Alps, did not witness this fact.—*Archives Generales.*

Song of the Blackbird.—M. Ducan states that in traversing the foot of the Apennines from Novi to Genoa and from Genoa to Carrara, he was surprised to find the song of the blackbird of those mountains different from that in France, and exceedingly melodious, though the species is the same. Perhaps this is more particularly the case during the pairing season. It has been repeatedly remarked that in Italy some birds sing better than elsewhere. Humboldt ascertained this to be the case with regard to the canary-bird and chaffinch.

The Italian Voices.—The inhabitants of the city of Bergamo, are celebrated throughout Italy for the melody of their voices. But they are also famous for the number of goitres to be found among them. Is it probable that the same circumstances which produce the melodious voice, also cause the morbid growth of the throat? It is possible, for the same coincidence was observed at Zama in Numidia, by Pliny and Vitruvius.

Nitrate of silver to the Nipples.—M. Berard, Jeune, has addressed a letter to the *Gazette Medicale*, denying the originality claimed respectively by Dr. Hannay, Dr. Bowen, and Dr. Jewel, in the employment of this remedy in the above case. M. Berard says it was so employed and mentioned by M. Beclard, more than ten years ago.

Illness in high life.—The Prince of Orange is at present suffering under a most severe attack of pleurisy. The Princess Lieven has been recommended by her physicians to leave Russia for a warmer climate, in con-

sequence of an inflammatory affection of the chest; and the Princess Esterhazy is slowly declining in health, under a scirrhous affection of the uterus.

Russian Apothecaries.—The number of apothecaries at present practising in Russia amounts only to 487—a fact which strongly proves the crushing influence used against all liberal professions by a despotic and tyrannical government.

APOTHECARIES' HALL.

Names of gentlemen to whom the Court of Examiners granted certificates of qualification on Thursday, January 23rd.—Joseph Hickson, Haslam, Market Drayton; Webster Adams, Needham Market; Thomas Tattersall Roscow, Haslingden, Lancashire; William Taylor Tyson, Canterbury; Walter Monkhouse, Penrith; Thomas Theodore Campbell, London; Henry Offrell Snowden, Ramsgate; William Archer, Sudbury, Suffolk; Francis Carbott Fairbank, Sheffield.

NEW BOOKS.

BRITISH AND FOREIGN.

A practical Compendium of Diseases of the Skin by Dr. J. Green.

Chemical Attraction, an Essay, in five chapters, by G. L. Hume.

Malgaigne, Manuel de Medicine Operatione fondée sur l'Anatomie Normale et l'Anatomie Pathologique.

Merat et De Lens, Dictionnaire Universel de Matiere Medicale et de Therapeutique.

Velpeau, De l'Operation du Trépan dans les plaies du Tête.

Rosion, Medecine Pratique Populaire—Secours à donner aux Empoisonnés, et aux Asphyxiés, et nouveau Traité d'Embryologie Sacrée.

Louis, Examen de l'Examen de M. Broussais, relativement à la Phthisie et à l'action Typhoïde.

This last work has just been translated by Mr. Charles Cowan, and will shortly be published.

An Exposition of the Nature, Treatment, and Prevention of continued Fever. By Henry M'Cormac, M.D., 8vo. pp. 202. London, 1835. Longman, Rees, Orme, Brown, Green and Longman.

[An exceedingly learned treatise on fever, including vast research, great observation of the disease, and a summary of ancient and modern opinions.]

The practice in the Liverpool Ophthalmic Infirmary, for the year 1834, being the first special report. By Hugh, surgeon to the charity, 8vo. pp. 55. A Plate, London, 1835. Longman and Co.; Liverpool, Grapel.

[A very good report of a Provincial Institution, which proves the author to be well acquainted with the diseases of the eye, with the best works on the subject.]

Tables and Diagrams of Chemistry and Pharmacy. By John Murray, M. D.

The Philosophy of Health. By Dr. Southwood Smith, Author of "A Treatise on Fever."

Observations on the Causes and Treatment of Ulcerous Diseases of the Leg. By J. C. Spender, Member of the Royal College of Surgeons in London. 8vo., pp. 210. London, 1835. Longman and Co.

—o—

CORRESPONDENTS.

A Portsmouth Subscriber.—We really know nothing of the two young gentlemen who lately ran away from Portsmouth, and attempted to bribe the guard of the Rocket, night coach, to bring them free up to London in the hind boot of the coach—they were a commission! from that renowned spot, St. Thomas's Hospital.

A Friend.—Drs. Graves and Stokes were the aggressors; and if they chose to attack us, they must be satisfied with our defence. There is a Jerry Sneak who has sadly imposed on both, to serve his own purposes; and nothing but a respect for the profession has hitherto restrained us from publishing their letters to us, which, unless further provoked, we shall not suspend at our publishers, after their own fashion at the office of the Portsmouth Cholera Gazette.—Two of these worthies most strenuously advised us and our Dublin friends to dissociate ourselves from the men they now patronize, be-

cause they —; but no—we shall not state the reason at present.

An Observer.—It is all the work of the penny-a-line men, who cater tomfoolery for the newspapers. The editors have nothing to do with it; they are too well informed to admit such ungrammatical trash. There must be something to fill up—the murder of a child, or suffocation of an old woman—anything.

A General Practitioner.—It was an awkward mistake to order a woman to be tapped to-morrow, after two months sojourn in an hospital; and on the morrow, that she should be found in labour and delivered. Simon Pure of the hospital must have been in extacy on going to remonstrate on the pettit treason committed by his patient on leaving the hospital, the only source of superior medical and chirurgical knowledge, until she was tapped, more especially when her mother exclaimed, "Why, she has got rid of her dropsy, and she has had a son this morning."—Well might the Fellow exclaim, "The d—l", and then run out of the house. The pure surgeons are not a whit less fallible. We could cite numerous cases, which have fallen under our own observation, in which have blundered as remarkably.

A Lover of Professional Etiquette.—It shews a narrow intellect, a bad feeling, and a certainty of failure.

Sheffield School of Medicine.—We regret to observe, by a Sheffield paper, that a brutish mob pulled down the School of Medicine at Sheffield, having first burned all books and papers they could find.—What barbarians!

ON

MEDICAL JURISPRUDENCE,

DELIVERED BY PROFESSOR A. T. THOMSON,

F. L. S.,

At the University of London; Session 1834-35.

LECTURE XVI.

Infanticide.

GENTLEMEN—We have now to inquire into the means by which the death of a new-born child may be caused.

I have already stated that infanticide may be traced either to *omission* or to *commission*; let us examine each, and the influence which it possesses in a medico-legal point of view, in fixing the crime of infanticide either upon the mother or any other suspected party.

If a woman be delivered at the full period, and the child be born without any assistance, and be found dead; if it appear that no preparations have been made for delivery; that no baby linen have been provided;—this is presumptive evidence of a previous intention to destroy the child, on the part of the mother: and yet this neglect may have proceeded altogether from ignorance; from an unconsciousness of the existence of pregnancy until it was fairly established; consequently, we may infer a difficulty in determining the probable period of delivery. Few women, however, obtain the age of puberty in this state of ignorance; and, unless great pains have been taken to conceal their state—which also implies an intention to destroy the infant—it is evident that the most inexperienced would receive advice on this subject, as soon as their situation becomes obvious, from the more experienced; and, therefore, ignorance can rarely be admitted as a plea in this case.

The death of a new-born infant may also be caused by omitting to remove it from that state of supination in which it generally lies when expelled from the vagina of the mother. It is easy to conceive a case of this description, in which a young woman

with her first child, and that an illegitimate one, may have been unexpectedly taken in labour, and, after the birth of the child, be unable to remove it, or be ignorant of the danger of permitting it to remain in the supine state until assistance be procured. The female, in such a case, may be accused of child-murder, and yet be perfectly innocent. Dr. Wm. Hunter, in his treatise on the uncertainty of the signs of murder in the case of bastard children, lays particular stress on cases of this kind; and illustrates the fact which he wishes to establish by the following case.—“A lady, at a pretty distant quarter of the town, was taken with labour pains in the night time. Her nurse, who slept in the house, and her servants were called up, and I was sent for. Her labour proved hasty, and the child was born before my arrival. The child cried instantly, and she felt it moving strongly. Expecting every moment to see me come into her bedchamber, and being afraid that the child might be some way injured, if an unskilful person should take upon her the office of a midwife on the occasion, she would not permit the nurse to touch the child, but kept herself in a very fatiguing posture, that the child might not be pressed upon or smothered. I found it lying on its face, in a pool which was made by the discharges, and so completely dead, that all my endeavours to rouse it to life proved vain.” If, in such a case, the mother be alone, every circumstance that can prove favourable to her should be inquired into by the medical witness; as the maternal instinct operates so strongly in favour of the preservation of the child, that we must imagine some strong reason for the non-operation of this, unless facts prove the contrary, before we can admit that the child has been wilfully murdered. Thus, it is possible that syncope may have taken place, or convulsions may have supervened the expulsion of the child, to prevent a mother from affording the necessary aid to her offspring. It is our duty to investigate these, and also to ascertain whether there may not have existed other circumstances which may have operated in producing death in such a case, be

fore we can concur in the crimination of a mother. A case illustrative of this fact is detailed in Burnett's *Treatise on the Criminal Law of Scotland*.

If the proper temperature of the body of an infant be not maintained after birth, or, if the child be starved, in both cases the murder of the infant may be regarded as an act of omission, but in general it is an act of commission; yet I have known cases of the most flagrant description connected with starvation.

In cases of this kind the age of the fœtus at birth should be ascertained; for if a child be born at the seventh month, or earlier, the utmost care may be taken to preserve it without proving successful. It is, however, not certainly ascertained how long a child can live after birth without nourishment. Foderè supposes that it is dangerous to extend the time beyond twenty-four hours; but many instances have occurred that life may be sustained immediately after birth for two and even three days; but much must depend on the state of the child at birth: whether it be delicate and of a spare habit of body, or vigorous and plump. If, on an examination of the alimentary canal, it be found completely empty, if the gall bladder be enlarged, and much bile be effused into the stomach and intestines, and at the same time the whole body be emaciated, and if the umbilical cord be also detached—a circumstance which rarely occurs until the fourth day—there can be one opinion only as to the cause of its death—culpable omission to administer nutriment.

Another frequent cause of the death of infants, arising chiefly from ignorance, is omitting to tie the umbilical cord. Although the danger of leaving this cord untied has been generally admitted from the earliest period down to the present time, yet some obstetricians have gravely contended that it is not essential for the preservation of the child; such is the opinion of Fontani, Alberti, Kaltamidt, and some other writers. It is not wonderful that a mother who has given birth to a child without assistance should neglect to put a ligature on the infantine portion of the cord, whether she cut or tear this asunder; but if this arise from ignorance, it can scarcely be brought forward as a proof of infanticide. A clever counsel may raise several questions upon this point, which it is proper you should be prepared to meet. Thus, it may be asked, Whether, in the event of the cord not being tied at all, and not divided until after the expulsion of the placenta, when all pulsation in the cord has ceased, and yet the child has been found dead—upon what signs would you be justified in referring the death of the child, in this case, to the navel cord not being tied? Now, as death from hæmorrhage of the umbilical cord must necessarily cause an empty state of the heart and blood vessels, it is evident that such a state of the circulating

organs will fully justify your opinion: on the contrary, if the infant have been murdered, and the mother set up a plea of hæmorrhage from the navel cord, arising from ignorance on her part, unless we find a deficiency of blood in the large vessels, especially the veins, and in the cavities of the heart, we cannot attribute the death of the infant to this cause. Nor is the evidence of hæmorrhage in this case strengthened by the presence of a large quantity of blood about the place where the child is found, or in the linen in which it may be rolled, for this may be put there by an artful woman to skreen her iniquity; and, under no circumstances can we admit that hæmorrhage has taken place, unless the large vessels and the cavities of the heart be empty. But a child may be destroyed by an hæmorrhage from the umbilical cord, and the cord be afterwards tied. In this case, the same examination, and an empty state of the heart and large blood-vessels, will unmask the deception.

Such are the principal causes of infanticide, by omission; we have now to notice the manner in which death occurs when it is the result of wilful violence; or, in testimonial language, of *Infanticide by commission*.

When a child has been found dead, and it has been determined that respiration had taken place, and, from other evidence, there is every reason to imagine that a murder has been committed, our first duty is to examine carefully every part of the body, and to determine, from the signs which this presents, the causes of death. I have already noticed the fallacies which may be fallen into regarding bruises; the appearance of ecchymoses, the bruised state of the fleshy parts of the body, and a tumour of the sinciput, may be referred to a severe and difficult labour; but when there is extensive contusion, with fracture of bones, and effusion of blood within the cranium, there can only be one opinion—that these signs must have resulted from violence. I have also stated to you, that child-murder has occasionally been perpetrated by thrusting sharp bodies into the brain, through the fontanelles. In the *causes celebres*, several instances of this kind are stated to have been perpetrated by a mad woman, who killed every new born infant that she came near, in order, as she affirmed, to people heaven with those devoid of acquired sin. She plunged the instrument which she employed into the nostrils, the ears, the temples, the fontanelles; she also pierced the thorax with a sharp needle, so as to lacerate the heart; and in one or two instances the spinal marrow was injured by the instrument being pushed in between two of the cervical or the dorsal vertebræ; or the abdominal viscera may be wounded by the introduction of a sharp pointed instrument into the rectum; thence the necessity of

examining closely every ecchymosis. But in doing this, too much caution cannot be exercised in distinguishing these ecchymoses from accidents which may occur during dissection.

Among other mechanical injuries inflicted in the process of delivery, we must not overlook the fracture, or rather luxation of the cervical vertebræ, which may be produced by forcibly twisting the head of the infant, and thus injuring the spinal marrow. When death results from such a cause, we must look for blood effused among the cervical muscles; and, not unfrequently, there is fracture of the first and second vertebræ; and the ligaments are either much stretched or forcibly ruptured. It may, however, be suggested, that such a state can be produced by violently twisting the head of a still-born child, by any designing individual, who may have a spite against the mother, and desire to bring her life into jeopardy. But such an opinion is easily refuted; for although luxation and fracture of the vertebræ can be caused by twisting the neck violently, after death, yet, in this case, the effusions and ecchymosis of which I have spoken, will not be present.

If the death have been the effect of strangulation, besides the livid mark of a cord round the neck, the face will be found livid, the tongue swollen and protruded, and the mouth frothy. The signs of this state, however, are best discovered by dissection of the contents of the cranium, and those of the thorax: the vessels of the pia mater, and the jugular veins, are generally found gorged with blood, and the lungs covered with ecchymoid spots. A barrister may put the question, in this case, Whether appearance of strangulation may not arise from the accidental twisting of the umbilical cord round the neck of the infant? It cannot be denied that the umbilical cord is frequently twisted round the neck of the infant; and, when it is unusually short, a mark may be left round the neck, closely resembling that left by strangulation after birth: but the case is easily determined by a post mortem examination of the thorax. If the death of the child have arisen from actual strangulation, then the lungs will be found in a dilated state; the pulmonary vessels tinged with blood; and the whole capable of floating in water; whereas, if the mark around the neck have been produced by the umbilical cord, the lungs will be found in the state of those of a still-born child. In giving an opinion, however, in such a case, we must bear in mind that the child may breathe when the head only is protruded from the vagina, and the cord may not be drawn tight until after this have taken place; so that with the signs of strangulation there may be those of perfect respiration, and yet no criminality attach to the mother. The presumption of violence may be great, yet it is only conjec-

tural; and, whenever the evidence falls short of positive proof, the benefit must be given to the woman. Indeed it should be regarded as an axiom, that in all cases in which the sensible evidence of wilful criminal violence is not perfectly demonstrative, no woman ought to be convicted of perpetrating infanticide. The natural instinctive feeling of maternal affection, which leads every mother to guard the life of her offspring, even when this is likely to heap disgrace upon her character, should always influence us in judging of appearances which lead to the supposition that violence may have been employed; for if the evidence be not perfectly decisive of criminal violence, we ought never to presume its existence, in the face of so powerful a principle as maternal affection.

When infanticide really occurs, drowning is not unfrequently the mode of causing the death of the infant. In this case, if the child were merely thrown into the water, the same struggling, the same buoyancy, and the same symptoms which, as I shall soon describe to you, occur in the adult who is drowning, take place in the infant; but, in general, the child is held down in the water until life be extinct, which seldom requires more than two or three minutes: suffocation occurs, and the surface of the body, although sometimes pale, yet is commonly of a purplish hue. Post mortem examination of the body displays the right side of the heart, and the large vessels connected with it, gorged with blood, while the left is often nearly empty; the pulmonary artery is tinged with black blood, and the bronchial tubes contain a certain quantity of frothy, aqueous fluid. This might lead us to suppose that the diaphragm would rise into the thoracic cavity, but the contrary is the case; the diaphragm is depressed into the abdomen; and this constitutes one of the most marked distinctions between drowning whilst alive, and mere submersion in water after death. In drowning, no expiratory act occurs, but from the sense of suffocation which is present, the efforts of inspiration are great, and tend to keep down the epiglottis until all consciousness is over; then a few bubbles of air rise to the surface; but although emptying of the lungs takes place to a certain extent, yet the depressed state of the diaphragm, which had previously taken place, remains. Another marked diagnostic sign is taken from the state of the blood, which is permanently fluid in a person who has been drowned, but is in a coagulable state if the person have died before being submersed in the water in which the body is found. The brain of those who are drowned presents a dull red hue on the surface, but the vessels are not so much gorged as in death from strangulation, neither is there any extravasation of blood, there being no obstruction to the return of the blood: in case of drowning; the suffocation arises

solely from the want of the oxidizement of the circulating fluid. Many of the signs of drowning, however, are similar to those arising from other causes; and therefore, you should be prepared to meet every difficulty which may be advanced by counsel, and be able to state those signs which are the most conclusive in deciding that drowning has been the cause of death in an infant found in water: one of these is the protrusion of the diaphragm into the abdomen; and another, provided the former be present, is the fluidity of the blood. With respect to the last, I say it can be admitted only if the former be present, because the blood also remains fluid in cases of death from the influence of some narcotic poisons, and of unrespirable gases, in which the infant may be immersed. It is necessary, however, to remark, that putrefaction renders these signs fallacious.

It now only remains to notice the method of examining the body in case of supposed infanticide. The object in this examination is chiefly to ascertain whether or not respiration had been effected; whether the child had breathed after it was completely born; whether it had died from strangulation, drowning, suffocation from unrespirable gases, or other means; or from blows or wounds. With these in view, the examination and dissection is to be thus conducted:—After careful external examination, noting down every unusual appearance, particularly whether putrefaction have taken place, and to what extent it has proceeded, so as to determine the probable period of the death of the child, and how this can be reconciled with the period of the supposed murder; whether the death have occurred in utero or after birth; if after birth, whether the state of the body can throw any light upon the manner or the cause of death. Having made and noted such appearance, we are next to proceed to open the body, and in so doing, we must examine first the cavities in rotation, beginning with the mouth. The first step of the dissection should be an incision, beginning at the lower lip and terminating at the sternum, and a transverse incision along the lower edge of the lower jaw, which, after the integuments are dissected back, is to be divided at its symphysis, the two portions separated, and the head bent back, so as to obtain a complete view of the interior of the mouth and fauces. The position of the tongue, in particular, must be examined and noted, and whether any foreign matter be found in the mouth. We must next lay open the trachea through its whole length, beginning at the larynx; if more fluid than natural be found in it this must be noted, both as regards quantity and its nature, whether frothy or otherwise: we must also note whether the bronchi be loaded with tenacious mucus, and if blood be mixed with it; as any of these circumstances will afford strong presumptive

grounds for suspecting that either drowning or some other means of suffocation have been the causes of death. At the same time new-born children are subject to epileptic fits, which cause much frothy mucus to be present in the mouth, but this rarely or never extends to the trachea. The frothy mucus in the trachea indicates little if putrefaction have taken place; thence the great importance of carefully noting the appearance and state of the body previous to dissection. The contents of the pharynx must also be noticed, and the excised part put into pure distilled water, in order to extract afterwards by boiling, any matter capable of being tested. The cavity of the thorax is next to be examined; and to expose this the scissors are to be used in preference to the scalpel in dividing the cartilages of the ribs, so as to remove the sternum, after the integuments have been divided and dissected back. The state of the lungs is now to be noted, particularly whether they fill the cavity of the chest or are compressed; and whether the diaphragm be pushed up or descend into the abdomen. The trachea is to be divided as near as possible to the lungs; the large vessels, both aorta and vena cava, are to be tied with two ligatures, and cut between these, so that the lungs may be removed from the body and weighed. The state of the cavities of the heart, whether the foramen ovale be open, or the ductus arteriosus contains blood, are next to be examined, and particular attention is to be paid to the state of the pulmonary artery.

Proceeding from the thorax to the abdomen, this must be laid open by the usual incisions, so as to form a triangular flap, at the lower part, which may be turned down, to permit the umbilical vessels to be examined. If these vessels and the sinus of the vena portæ be found completely exsanguine, suspicions of hæmorrhage having been the cause of death will be greatly strengthened. Every discolouration of the abdominal viscera must be accurately noted down, with the appearance of the liver, and the ductus venosus, previous to the opening any of the viscera. After tying all the vessels connected with the liver, this should be removed. The stomach must next be opened and the œsophagus should be slit up and examined. Should the stomach contain much water, although this be not an essential consequence of drowning, yet it strengthens the suspicion of that event. Little satisfaction can be obtained from examining the intestinal canal, unless we suspect that poison has been administered: but the empty or full state of the urinary bladder should be carefully noted.

The examination of the head requires every attention; and young anatomists and practitioners, frequently defeat the object of their investigations from want of delicacy in managing this part of the dissection.

After having ascertained that it displays

no bruises but what may have occurred in a severe labour; that no ecchymosed spots proceed from punctures, and that the bones are free from fractures and depressions, we are to make a longitudinal incision through the integuments, beginning at the lower part of the forehead and terminating at the second or third cervical vertebra; and then a transverse incision, at right angles to the other, from ear to ear; so that by dissecting back the integuments the whole of the cranium may be exposed. The bones are next to be carefully removed by the aid of the scissors and the handle of the scalpel, having previously noted the appearances on the interior of the scalp; and the utmost care must be taken to prevent laceration in this part of the dissection. The anatomist must now examine the state of the dura mater, whether it be red or inflamed; and if so, whether these spots of redness correspond with bruises on the surface of the integuments; as a strong proof of criminal violence may be drawn from such a correspondence. He must also carefully notice whether any bloody serum be effused under the dura mater. A deep red and inflamed appearance of the cortical substance of the brain,

also, with ecchymosis of the scalp, is a strong proof against the accused. The last step of the examination is to ascertain the state of the spinal column and its contents; and this is best effected by the use of the circular saw and a pair of sharp bone nippers, by the aid of which the spinous portions of all the vertebræ may be readily removed, and the whole medullary column laid bare. In making this examination, it is necessary to put down every thing on paper; and to trust nothing to memory; and, whilst we feel a just abhorrence for a crime which pre-supposes the obliteration of the best feelings of our nature, and which, if slightly punished when confirmed, would lead to the most awful consequences, we must always bear in mind the state of mind of a young female reduced to the temptation of committing such a crime as infanticide, for the sake of character; must bear in recollection that this state has probably been the result of the arts of a base seducer; and although we cannot palliate the crime, yet that we should be slow to condemn; and certainly never, without the clearest demonstration of guilt, place either the character or the life of a woman in jeopardy.

LECTURES ON THE INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE IX.

Continuation of the Tissues—The Fluids.

As a proper Nervous, so a proper Muscular Tissue does not, in all probability, occur in any plants, and many of the lowest tribes of animals are likewise destitute of it. This appears to be the case with all the Zoophytes; and indeed in any of the invertebrate tribes of animals this tissue is not easily recognizable from the cellular—so difficultly, that by some authors (a) a proper Muscular Tissue has been denied to them all. On the other hand, the number of distinct organs performing the office of muscles, and therefore to be looked upon as composed of a colourless and jelly like muscular tissue proper to these animals, is in some invertebrate animals almost incalculable (b). And in the lower orders of even the vertebrate animals, the muscular tissue presents a very different aspect from what it has in the higher; being, in most fishes, white, flaky, and without tendons, and in reptiles in general, although of a deeper colour and more rounded, still without tendons, and very dissimilar in its general characters from that of birds and mammals. In the latter, and particularly in man, it is more or less distinctly divisible, like the Nervous Tissue, into two varieties, the one unconnected with the skeleton, and generally in contact with mucous membranes, as in the air-passages, the gullet, stomach, and intestinal canal, the ducts of all the proper conglomerate glands of the body, the gall-bladder, urinary bladder, and urethra, and Fallopian tubes, the vesiculæ seminales, and the muscles moving the small bones of the ears—the only exception to the latter condition being in the heart, the

(a) Oken.

(b) Lyonnet, many years ago, enumerated upwards of four thousand muscles in the caterpillar, many of which he described and

delineated; and similar descriptions and delineations of the muscular apparatus of other invertebrate animals have been given lately by Straus, Newport, and others.

parenchymatous tissue, and the irides—the other attached, directly or indirectly, to the skeleton, whether connected or otherwise with the mucous membranes, as in the muscles which dilate and contract the chest, those by which the voice and speech are affected, those by which the aliments are taken, and the voiding of the stools and urine assisted, those by which the organs of the senses are directed to their proper objects, and those, lastly, by which the various positions and motions of the head, trunk, and extremities are regulated. Of these, the former, then, may be called the Internal Muscular Tissue, as appertaining chiefly to the contained, the latter the external, as appertaining chiefly to the containing parts of the body (*a*). Both are characterized by a red colour, opacity, a spongy inelastic consistence, and a fibrous structure, and both have their fibres connected together by a fibrous membrane, which, becoming condensed on the surface, or at the extremity of a muscle, constitutes, where these are met with, its tendon, fasciæ, aponeuroses, &c. The chief distinctions, in the meantime, between the two varieties of the muscular tissue are that

In the Internal Muscular Tissue,

The colour, with few exceptions, is faint;

The consistence is comparatively firm;

The apparent fibres are small, and rather interwoven together, than placed parallel with each other;

The fibrous membrane connecting these is seldom condensed into a tendon;

The blood-vessels and nerves are comparatively numerous, but small.

The primitive muscular fibre has been successively represented as composed of strings of vesicles (*b*)—quite distinct from the solid globules already alluded to—as tubular (*c*), as solid, and cylindrical (*d*), and as flattened or prismatic (*e*), and its diameter, while it is by some writers stated to be seven times greater than that of the red globules of the blood (*f*), is by others described as not exceeding one third (*g*), one fifth (*h*), or even one eighth (*i*) of their diameter. We must remember further that the size of these red globules themselves is by no means established. The primitive muscular fibre is in general said to be somewhat tortuous in its course, perhaps, as in the case of the nervous fibre, to compensate for its want of elasticity; by some physiologists, however, it is represented, on the contrary, as quite straight (*k*). The collective muscular tissue of the human body, constituting, as it does, not fewer perhaps than between four and five hundred muscles attached to the skeleton alone, and—if we admit its co-existence with the parenchymatous tissue—entering, as it must do, into every other organized tissue, is to be regarded as by far the most abundant of all, and as constituting a very great proportion of the weight, and a still greater proportion of the bulk of the whole body, although it is impossible of course to estimate this proportion with any thing like precision.

Of the Unorganized Tissues, whether of plants or animals, it is unnecessary to speak in

In the External Muscular Tissue.

The colour is commonly deep;

The consistence is comparatively soft;

The apparent fibres are larger, and in general run parallel with each other;

The fibrous membrane connecting these commonly forms a tendon;

The blood-vessels and nerves are comparatively few, but large.

(*a*) The muscles were not enumerated by the ancients among their *σπολιμενῆ*, because they were considered to be a mere mixture of the Fibrous and Nervous Tissues; and even so lately as the time of Stenon, no difference was presumed to exist between a tendon and a muscle, except that, in the former, the fibres were “*arctæ*,” and, in the latter, “*laxæ inter se conjunctæ*.” (*De Musc. et Gland.* 1683). The muscular Tissue was regarded by Vieussens, Quesnay, Mascagni, and others, as directly composed of blood-vessels; and a vague hypothesis—which appears to have originated in the observation of the effects of certain stimulants applied to all appearance directly to the muscular fibre—that muscles were merely expansions of nerves, the two together constituting what was called the *Solidum Vivum* of the body, was for a long time prevalent in the schools of medicine. This hypothesis the second Dr. Monro thought it necessary, so lately as the year 1783, formally to refute (*On the Nervous System*); and certainly, if distinct anatomical, chemical, and

vital properties can entitle any tissue to be regarded *sui generis*, the muscular has a better right than most others to be so reputed. The division of this tissue into two varieties was proposed by Bichat, under the names, however, of Muscular Tissue of Organic, and Muscular Tissue of Animal life; for which the names Internal and External have been above substituted, for reasons already mentioned when on the subject of a similar division of the nervous tissue.

this place, since they have all been alluded to incidentally, after each of those organized tissues with which they appear to be most immediately connected.

The other component parts of an organized being are its fluids. The following are the principal fluids.

OF PLANTS IN GENERAL.

The **CRUDE FLUIDS**, or those which ascend by the spiral vessels and their numerous modifications to the vesicles of the leaves, or corresponding organ; called collectively the *Sap*.

The **MATURE FLUID**, or that which descends by the entire vessels from the vesicles of the leaves or corresponding organ; namely, the *Cambium*.

That **SECRETED FROM THE SAP**, and deposited, in Plants which breathe by the vesicles of the leaves, in those vesicles, namely, *Carbonic Acid*.

Those **SECRETED FROM THE CAMBIUM**, all which appear to be deposited directly in proper utricles composed of Cellular Tissue, and consist of the *Oils*, fixed and volatile, the *Turpentine*s, the *Balsams*, the *Gum-resins*, &c., each of which containing two or more of the reputed proximate principles of vegetables, such as Stearin, Elain, Resin, Acid, Extractive, &c., while there are besides innumerable others, which, as consisting of only one such proximate principle, will fall to be enumerated elsewhere.

OF ANIMALS IN GENERAL.

The **CRUDE FLUIDS**, or those which are returned by the Veins and Lymphiferous or Chyliferous vessels to the lungs or corresponding organ; namely, *Venous Blood*, *Lymph*, and *Chyle*.

The **MATURE FLUID**, or that which proceeds by the arteries from the lungs or corresponding organ; namely, *Arterial Blood*.

Those **SECRETED FROM VENOUS BLOOD**, either mixed with *LYMPH* and *CHYLE*, or alone, and deposited, in Animals which breathe by lungs, in the air passages, namely, *Carbonic Acid*, or in the ducts of the liver, namely, *Hepatic Bile*.

Those **SECRETED FROM ARTERIAL BLOOD**, and deposited—

1st. Directly on expanded surfaces, when they are called *Perspired Secretions*, as the *Halitus from the Lungs*, the *Halitus of the Serous Sacs*, the *Gastric Fluid*, the *Menstrual Fluid*, the *Humours of the Eye*, the *Fluid of Cotugno*, the *Fat*, the *Sweat*, the *Marrow*, the *Sinovia* and the *Buccal Fluid*.

2nd. Directly in follicles, when they are called *Follicular Secretions*, as the *Mucilage*, the bitter portion of the *Cystic Bile*, the *Stools*, the thick portion of the *Semen*, the *Fluid of Meibom*, the *Cerumen*, and the *Sebaceous matter of the Surface*.

3rd. Directly in the ducts of glands, when they are called *Glandular Secretions*, as—besides those already mentioned as secreted from Venous Blood—the *Pancreatic Fluid*, the *Urine*, the *Milk*, the thin portion of the *Semen*, the *Tears*, and the *Saliva (a)*.

(a) To say nothing of the classification of the fluids of plants, the origin of the study of the fluids of animals, and particularly of man, preceded by many ages that of the study of the tissues, ancient as this was; but it is of no interest at present to know the crude speculations, upon this subject, of the ancient philosophers and physicians, any further than it furnishes us with a key to that system of pathology, which, under the name of the *Humoral Pathology*, maintained undisputed possession of the medical world for upwards of two thousand years, and the vestiges of which are still obvious in many of our most familiar phrases and allusions. It is sufficient at present to observe that they admitted only four primary or asserted fluids—to wit the blood, the mucilage or phlegm, the yellow bile, and a supposed black bile. Το δὲ σῶμα τοῦ ἀνθρώπου, says Hippocrates, ἔχει ἐν ἑαυτῷ Ἄιμα, καὶ Φλέγμα, καὶ Χολήν διττήν ἡγόν, Ζανθήν τε καὶ Μέλαιν. (*De Nat Hom.*) and it was from some loss of balance of these in certain parts of the body, and not, as is commonly believed, from any vitiation of them, that diseases in general

were supposed to arise. All the other fluids in the mean time, were looked upon as little more than accidental, and the purgings, as it were, of these four. Since however the subversion of these visionary notions, and the establishment of so many real and tangible fluids in the human body, the classification of them has become a matter of some importance. Accordingly, by Pitcairn and Michelot they have been arranged with reference to their mechanical properties, into thick and thin; by Haller, with reference to their preponderating proximate principles, into Aqueous, Mucilaginous, Oleaginous, Albuminous, Gelatinous, Fibrinous, and so forth: and by others, with reference to their supposed physiological properties, into living and dead. The classification followed above is founded on those of Blumenbach and Chaussier respectively—the former of whom speaks of the fluids in general as crude, mature and secreted, while the latter subdivides the last into perspired, follicular and glandular. It is hardly necessary to say however that, in a subject of this kind, every man is at liberty to follow whatever arrangement he consider

The *sap* of plants is of course confined to those tribes which have a proper vascular Tissue; and the same thing may be said of the *venous blood, lymph, and chyle* of animals. In the former case the great bulk of the fluids, at any time in the ascending vessels, is derived immediately from the soil. Plants having no circulation, properly so called—but, in the latter, the great bulk of the venous blood, lymph, and chyle, is derived immediately from the arterial blood, to which more or less has been added from the other parts of the body, solid and fluid, by means of absorption, so that all these fluids are sometimes considerably different, as taken from different vessels (*a*). And so rapid and incessant are these conversions, on the one hand, of arterial blood into the fluids under consideration, and, on the other, of these again into arterial blood, that none of them can be said to be for a sufficiently long time identical, while circulating in their vessels, to enable us to infer any thing respecting their properties under these circumstances, from those which they display when stagnant in a tea-cup (*b*). With respect to their physical properties, the following are the

	Of Venous Blood.	Of Lymph.	Of Chyle.
Colour,	Modena red;	Rose red;	White;
Aspect,	Semitransparent;	Transparent;	Opake;
Consistence,	Viscid;	Viscid;	Viscid & oleaginous
Specific gravity,	1051;	1025;	p

It appears, however, from recent investigations, that venous blood, while in the course of circulation, consists entirely of a colourless, transparent, viscid fluid, strictly sui generis, and called liquor sanguinis, in which float the red particles, and that it does not hitherto contain, in a state of permanence, any one of the proximate principles which it afterwards manifests; but that when drawn from its vessels this liquor sanguinis soon coagulates, and subsequently separates into what are called the serum and crassamentum, in the former of which become now fully developed the sodo-albumen, oil, extractive and salts, and in the latter the fibrin, while the red particles—which the latter has involved, as well as a large proportion of the serum also—contains the hematosin and the oxyd of iron (*c*). If this be the case, the rapid coagulation of the venous blood, when out of the course of circulation, or rather its non-coagulation while still circulating, is no longer a problem, since it is obviously to be ascribed to the perpetual molecular changes which, in the latter case, it is undergoing, and which are incompatible with the full development of that principle on which its coagulation depends (*d*). And the same thing may be said probably of lymph

calculated to inculcate the most useful associations—the only legitimate object, at any time, of classification, which is not the mistress of science, but her handmaid—*Egregia illius Ancilla, non alia peior domina*.

(*a*) It was the venous blood alone which the immediate followers of Thales and Pythagoras included among the four primary fluids lately alluded to; the existence of arterial blood not having been generally admitted till the time of Galen; the arteries—as indeed the name implies—having been previously represented as containing air only. The chyle has been known as a distinct fluid since the time of Aselli (1622), the discoverer, not indeed of the existence, but of the functions of the chyliferous vessels; and the lymph, since that of the two Hunters (1762), and their immediate disciples. Le Gallois and Flandrin principally have been instrumental in shewing that the venous blood is of a different character, as taken from different veins; and Reuss, Emmert, Vauquelin, Brande, and Marcet, in establishing the same fact, with respect to the lymph and chyle.

(*b*) A very rough estimate will be sufficient to demonstrate this. Thus, if the left heart of man send two ounces of blood into the arteries at each beat, and beat eighty times in a minute, it will renew every drop

of arterial blood, at any given time in the body—say six pounds, in little more than half a minute; and as these six pounds must pass, in this time, into the veins and lymphiferous or chyliferous vessels, it follows that every drop of these fluids at any given time in the body—say thirty-six pounds—must be renewed in about three minutes and a half. But every particle of arterial blood is decomposed in the parenchyma of the body, and every particle of venous blood, lymph, and chyle, is decomposed in the parenchyma of the lungs. The above, therefore, are the extreme periods of the retention, by any one of these fluids, of its identity.

(*c*) Dr. Babington (*Med. Chir. Trans.* 1831).

(*d*) The spontaneous changes which the blood undergoes when out of the course of circulation, and particularly its coagulation and separation, have been a favourite subject of investigation since the times of Harvey, Lower, Malpighi, and Borelli; by whom, and their successors, the last-mentioned changes have been ascribed in general either to the contact of the air, or to the loss, sometimes of heat, sometimes of motion, sometimes of vitality. But the blood coagulates and separates equally well in various gases, and even in vacuo, as in the atmosphere, equally well when agitated as when at rest; equally

and chyle also, which appear to differ from venous blood, principally in both containing fewer red particles, while the latter again has more oil, on which its opacity depends, as well as some sugar: it is a mistake, however, to imagine that its properties are materially affected by the character of the aliment, from which indeed it would be easy to prove that only a very small proportion of it is derived (*a*). The red particles of these fluids, which constitute about twelve parts in a hundred of venous blood, but are much less abundant in lymph, and still less so in chyle, have been very generally described as consisting of a central, colourless nucleus surrounded by a red vesicle (*b*); and it was till very lately supposed that the globules recently alluded to as found in the several Tissues and other Fluids, were merely these nuclei, but without their red envelopes, as it was, that the coagulation of the venous blood, lymph, and chyle took place from the coalition with fibres of the same nuclei, which had previously shuffled off their red envelopes (*c*). It has been for some time, however, known that these fluids, when drawn from their vessels, soon display globules quite distinct from their red particles—and they are in fact the only fluids, it is said, which really contain any such globules—and that it is upon the coalition of these, which have been called lymph globules, that their coagulation, at least in part, depends (*d*); while the recent observations, on the one hand, that these red particles really contain no such nuclei (*e*), and, on the other, that it is from the liquor sanguinis, and not from the red particles, that the clot is formed (*f*), are sufficient to establish it that the coagulation of these fluids is quite independent of the red particles which they contain. With respect to the number, size, and form, of the proper red particles of these fluids, there has been the utmost discrepancy. The prevailing impression is, that they are less numerous and larger in fishes and reptiles than in any other vertebrate animals, while they are most numerous and smallest in birds, and that in all the lower animals they are more or less oval or elliptical. In man their size has been represented at different times as between the 6000th and 3000th of an inch in diameter (*g*); while their form has been

well, or better, when heated than when exposed to cold; and to attribute these changes to a loss of vitality, is to impose upon ourselves the onus of proving that it ever possessed this property—a task, as will be in future shewn—of no little difficulty. The blood coagulates and separates under any circumstances in which it is allowed fully to develop its fibrin, even though within the body, as in an ecchymosis—nay even though within its own proper vessels, provided it does not pass, at rapid intervals, through the parenchyma, as in an aneurismal sac; and the opinion that it is by the repeated decompositions which it undergoes in the parenchyma that these changes are obviated, is supported, among other things, by the fact, that in all inflammatory diseases, which are seated principally in the capillary arteries—the healthy office of which seems to be to decompose it—the tendency to these changes is increased, whereas in all congestive diseases, which are seated principally in the radicles of the veins—the healthy office of which seems to be to re-compose it—this tendency is more or less counteracted. But on this subject more hereafter.

(*a*) From the rough estimate lately made, it will appear that the left heart of man sends out nearly fifteen thousand pounds of blood daily; and of this, supposing the veins and lymphiferous or chyloferous vessels to bring back each in proportion to their respective capacities, the former will return about ten thousand pounds, and the latter about five thousand. Now, we can hardly estimate the capacity of the chyloferous vessels at less than one fiftieth of that of the whole lymphiferous and chyloferous system; so that they would transmit, say one hun-

dred pounds of fluid in the four-and-twenty hours, although they received nothing whatever from the aliment; and the utmost that this can add to such a mass—presuming the greater part of the watery and alcoholic portions to be taken up by the veins—does not exceed a very few ounces, the principal elements of which, moreover, are precisely the same, whether the food have been vegetable or animal! It is a common-place and erroneous view of the matter to regard the lymphiferous and chyloferous vessels otherwise than as instrumental, essentially to circulation, and adventitiously only to absorption—they are in every respect analogous to veins, and are equally continuous with the arteries, as originally assumed by Bartholin, and proved by Nuck, Cowper, and Ruysch, as veins are; and the Hunters and their school have done an irreparable injury to science by diverting the minds of physiologists from this relation.

(*b*) The discovery of these red particles of the blood was one of the first effects of the application of the microscope to philosophy, and was made by Leeuwenhoek, about the year 1675. The description of their structure, above alluded to, is that of Hewson, corroborated by Dr. Young.

(*c*) Dumas and Prevost.

(*d*) Home and Bauer (*Phil. Trans.* 1811).

(*e*) Hodgkin and Lister (*Phil. Mag. and Ann. of Philosophy*, 1827).

(*f*) Babington (*Med. Chir. Trans.* 1831).

(*g*) Home represents them as the 6000th part of an inch in diameter, Haller as the 5000th, Wollaston as the 4900th, Young as the 4416th, Blumenbach as the 3300th, and Sprengel as the 3000th.

described sometimes as spherical (*a*), and at others as oval (*b*), lenticular (*c*), annular (*d*), flat, with rounded edges (*e*), or altogether irregular (*f*): the general opinion appears to be that they are spherical—but fortunately the determination of the question does not appear to be of much importance. The average quantity of venous blood, lymph, and chyle in the body of an adult human being, at any given time, has been above represented as thirty-six pounds—twenty-four of the first, and twelve of the two last—assuming that the average quantity of the whole blood is thirty pounds, but upon this subject also there is great discordance of opinion (*g*): it is pretty well established, however, that the relative quantity of venous blood is greatest in old persons and males, and that of lymph and chyle in young persons and females, for reasons already assigned.

As the great bulk of the venous blood, lymph, and chyle, is derived immediately from the arterial blood, to which some additions are made by absorption from various parts, so the great bulk of the *arterial blood* is derived immediately from the former fluids, to which, perhaps, something is added in the way of absorption by the pulmonary veins (*h*) from the lungs; but nevertheless the arterial blood, as formed in one definite organ only, is, unlike the fluids just mentioned, precisely of the same character, from whatever artery it be taken (*i*). With respect to its physical properties, the following are the

(*Of Arterial Blood*)

Colour, . . . Bright Scarlet;
Aspect, . . . Semitransparent;
Consistence, . . Viscid;
Specific gravity, 1049.

Its nature, while circulating, appears to be similar to that of venous blood, and the spontaneous changes which it afterwards undergoes are likewise similar to those sustained by venous blood, lymph and chyle, and to be explained in the same manner: it is said, however, to undergo these changes somewhat more quickly. It contains, also, a greater number of the red particles. The average quantity of arterial blood, at any given time in the body of an adult human being has been represented, on the premises already assumed, as six pounds; but the relative quantity is greatest in children and females.

Of *Carbonic acid*, as a secretion from the sap of plants, and from the venous blood, mixed with the lymph and chyle of animals, it is unnecessary to take notice in this place, further than to shew that its insertion here was not unadvised. That it is not formed by the direct combination of the oxygen of the air with the carbon of the venous blood, in the respiratory organs is rendered certain, by all the arguments brought forward to prove that the whole of the oxygen which disappears in respiration is absorbed into the arterial blood (*k*); and that it does not, nevertheless, reach the respiratory organ ready-made with the venous blood, is established by the fact that no such carbonic acid is contained in this fluid (*l*). On the other hand, the eminently philosophical views that have lately been taken, as well of the general structure of the lungs—which are now properly described as a large conglomerate gland (*m*)—as of the particular relation which subsists between this organ and the liver—direct, as to structure and function, and inverse, in all tribes of animals, under all circumstances, as to size and importance (*n*), is decidedly in favour of the opinion that the carbonic acid, voided in respiration, is, not only a secretion, but one of which hepatic bile is in some measure vicarious. Whether the quantity of oxygen which has been absorbed, determines that of carbonic acid to be secreted, or the quantity of carbonic acid which has been secreted determines that of oxygen to be absorbed—so that the two are found very nearly to correspond—will fall to be considered

(*a*) Leeuwenhoek, Haller, Blumenbach, Cavallo, Rudolphi, &c.

(*b*) Sprengel, &c.

(*c*) Hewson, Falconer, &c.

(*d*) Delatorre, &c.

(*e*) Hodgkin, Lister, &c.

(*f*) Amici, &c. As Dr. Milligan expresses it, they have been compared “to a globe, to a bladder with a pea in it, to a piece of money, to a drum, to a candlestick, to a hexaedron, and I know not what;” and, according to Magendie, they may be made to present almost any form—“suivant qu’elles soient placées exactement, ou inexactement, au foyer du microscope.” (*Précis de Physiol.* 1816.)

(*g*) By Harvey, Allen Mullen, Abildgard, and Blumenbach, the whole quantity of

blood is computed at only 8 lbs.; by Lower at 10; by Sprengel at from 10 to 15; by Borelli at 20; by Quesnay at 28; by Haller—the estimate followed above—at 30; by D’Hamberger at 80; by Keill at 100.

(*h*) See the experiments of Autenreith, Mayer, Magendie, and others, in proof of the great absorbing power of these vessels.

elsewhere. The average amount of carbonic acid excreted daily, is, in man, about forty-six thousand cubic inches, the weight of which is about forty-three ounces (a).

Hepatic Bile is still more certainly a secretion from the blood of the Vena Portæ, than Carbonic Acid is from the Pulmonary Artery, since the former fact may be proved by direct experiment (b); nor do the cases on record in which this vessel did not go to the liver, while nevertheless bile was found in the gall bladder (c), tend at all to invalidate this conclusion, since a great proportion of the cystic bile is always a secretion of the hepatic artery, no branches of the vena portæ being distributed upon the gall bladder. Hepatic bile differs in its physical properties from cystic bile, principally in being destitute of all bitterness; which is the case of course with all animals destitute of a gall bladder. It is in all probability, like carbonic acid, formed only to be evacuated, when it passes directly into the intestines; but that portion of it which reaches the cystic duct and gall bladder, and is mixed with the bitter secretion of these organs, perhaps performs some obscure end in the animal economy. The diurnal amount excreted, since it is only with the stools that it can pass out of the body, is not easily estimated; but it is probably very small (d).

Of the fluids above enumerated, as secreted from the Cambium of plants, nothing needs be said at present; and of those secreted from the arterial blood of animals, it is not necessary to speak particularly. They are commonly described as either secretions or excretions; but the distinction is not precise, and, what is worse, it is illogical, since all excretions are secretions to begin with. Of these fluids some are passing out of the body, more or less, continually; others at regular or irregular intervals; others only accidentally, and being in general re-absorbed; and others never under any circumstances, being always so re-absorbed, or otherwise disposed of within the body.

As examples of the first, in addition to the carbonic acid and hepatic bile already spoken of, are the *Halitus from the Lungs*, amounting on an average perhaps to ten ounces in the day; the *sweat*, insensible and sensible, to about forty ounces (e); the stools, which are not, as is commonly supposed, merely the residual parts of the aliment, but a proper secretion from the follicles of the large intestines, analogous to the ambergris of the white Whale (*Physeter* 42), the civet of the Pole-cat (*Viverra* 49), &c., and which in conjunction with the bile, do not on an average exceed five ounces (f); and the urine, amounting perhaps to about thirty-two (g). On the whole, then, the human body voids day by day about one hundred and thirty ounces in this way; which, estimating the quantity of absorbed oxygen to weigh the odd thirty ounces, leaves about one hundred to be supplied by the aliment.

To the second head of Fluids belong the *Menstrual Fluid*, the *Milk*, and the *Semen*. The quantity of the first passed by the women of this country at each menstrual period, is perhaps from three to six ounces (h); that of the others has not been estimated.

To the third head belong the *Mucilage*, the *Tears*, and the *Saliva*, each of which, at least as occurring in man, is intended by Nature to be re-absorbed in proportion as it is deposited, a certain quantity being always present for a specific purpose; and it is only from the habitual cataract more or less constantly prevalent in cold climates, or from the practice of snuff-taking, that an overflow of the mucilage of the nostrils ever takes place, as it is only from mental emotions or other accidental causes that the tears are ever in excess, and from other mental emotions, or from smoking, chewing tobacco, and so forth, that spitting is ever necessary (i). In some animals, however, as the Java Swallow (*Hirundo* 38),

(a) Davy says 45,504 cubic inches, Lavoisier, 46,037, Menzies, 51,840.

(b) See the *Annali Univ.* for 1825.

(c) Abernethy (*Phil. Trans.* 1793), Powell (*On the Bile, &c.* 1800), Lawrence (*Med. Chir. Trans.* 1814).

(d) By Glisson the diurnal amount of the whole bile was computed at two ounces only, and by Haller at twenty. Magendie thinks it probable that it is about two pounds.

(e) The results of calculations by Sancto-rius, Dodart, Keill, De Gorter, Lavoisier, Séguin, Abernethy, Cruikshank and others of the diurnal amount of transpired halitus are most discordant: perhaps, however, that above stated is an approach to the average in temperate climates and weather.

(f) Sanctorius says four ounces; Keill five.

(g) Sanctorius estimates it at 16 ounces;

Keill at 30; Prout, who is followed above, at 32; Bostock at 40; Haller at 49.

(h) According to Leroy, Baudeloque, De Haen and Smellie, the average quantity is 3 ounces; according to Haller, Astruc, and Burns, it is 6; according to Rousset and Friend it is 13; and according to Hippocrates it is 20.

(i) The countenance extended in this country to the unnatural practice of blowing the nose is an excellent example of the adaptation of the tastes of man to his necessities. In ancient Rome a man might divorce his wife for this offence; and in Persia, and other warm regions, it is not less abominated at present. It is no more intended by nature that the nose should require wiping, than that the urethra, or any other mucous passage should stand in need of the same operation.

the mucilage of the gullet and stomach is periodically voided in large quantities, in order to furnish the materials from which it constructs its nest; and it is of a similar fluid, drawn from a specific apparatus, and inspissated by its absorption of the oxygen of the air, that the Cockle (*Cardium* 9), forms its byssus, the Spider (*Aranea*)¹⁷ its web, and the Silk-worm (*Phalœna* 20), its cocoon. The venom of serpents is, in like manner, analogous to saliva. The quantity of mucilage, tears, and saliva at any given time present in the human body is not easily ascertained; but when we take into consideration the immense extent of the mucous surfaces, it will be obvious that that of the mucilage at least must be very considerable (a).

The remaining Fluids, or those which are constantly so re-absorbed, or otherwise disposed of within the body, are the *Halitus of the Serous Sacs*, the *Gastric Fluid*, the *Humours of the Eye*, the *Fluid of Cotugno*, the *Fat*, the *Marrow*, the *Sinovia*, the *Buccal Fluid*, probably the *Cystic Bile*, the *Fluid of Meibom*, the *Sebaceous Matter of the Surface*, and the *Pancreatic Fluid*. They are all present in very small quantities, perhaps at any given time, with the exception of the fat, which, upon an average, amounts to about one twentieth of the weight of the body, or between seven and eight pounds in a middle-aged man of moderate size and obesity; its relative quantity, however, is generally greater in the two extremes of life, and in females.

(a) By Haller the quantity of mucilage secreted every day by the intestines alone is computed at eight pounds; but this affords no criterion for judging of the quantity at any given time present in this canal; and the same may be said of the estimates of the

quantity of secreted saliva, which, according to Nuck is eight or ten ounces in the day, according to Cruikshank a pound, according to Paris from five to eight ounces every meal.

CLINICAL LECTURES,

By DR. RYAN,

Delivered at the Western Dispensary, Westminster;

Session 1834-35.

LECTURE I.

Pathology and Treatment of Dropsy—Supervention of Disease after Scarlatina, followed by Convulsions and Death in a few hours—Malignity of Scarlatina—Purulent Discharge from the Nostrils and Ears—Remarks on Scarlatina—Dropsy in a Child treated with Elaterium—Utility of combining various Remedies—Dropsy supervening immediately after Parturition.

GENTLEMEN—I have selected for this day's lecture a few of those cases of dropsy which you have observed; and as some of the patients are still under treatment, you will have an opportunity hereafter of witnessing the results of the practice employed. Before I narrate the history of the cases, I shall briefly remind you of the pathology, etiology, and treatment of the disease denominated dropsy. It consists in a preternatural effusion of serum, or the watery part of the blood, into the cellular or serous membrane of a part or the whole of the body. Thus nosologists describe dropsy of the brain, chest, abdomen, flesh, eye, spine, tunica va-

ginalis testis, uterus and ovary. In all these parts there is serous or cellular tissue, but according to modern physiologists these are identical in the embryonary state of organization. The exhalent vessels in health deposit a quantity of fluid, which is removed by the absorbents; but when the effusion of this fluid is greatly and inordinately increased, the absorbents cannot remove it, and accumulation of it, or dropsy, is the result. The equilibrium between exhalation and absorption is deranged, the one function predominates over the other, and disease is the consequence.

The exciting causes of dropsy are all diseases which impede the free circulation of the blood, as enlargement of the liver, which presses on the portal vein, impedes the circulation from the abdominal viscera, and determines blood to the peritoneum or serous coat of the bowels; diseases of the heart and kidney, and lastly, certain diseases of the skin. When there is disease in the right side of the heart, which impedes the circulation of the venous blood of the whole body, there is a congested state of the serous or cellular membrane of all parts, and the result is effusion or dropsy. When one or both kidneys are diseased, and do not perform their function of eliminating or disposing of a great portion of the serum of the blood by urine, it must in some degree be carried off by the skin or lungs; but these organs cannot perform an office for which they are very partially intended, the serum accumulates, and forms dropsy in some part or other. When the skin is diseased, as in scarlatina, and its function deranged, we often observe

dropsy as a consequence; and so with regard to the lungs, for at the approach of death in phthisis, we frequently see œdema or dropsy of one or both lower extremities. The functions of the skin and lungs in giving an outlet to some portion of the serous part of the blood, are secondary to that of the kidneys; and therefore if the latter act freely in phthisis or after scarlatina, dropsy may be prevented in most cases; but even these organs are overpowered, if I may use the term, when there is a general congestion of venous blood caused by organic disease of the liver, heart, or by morbid tumours pressing on the large venous trunks; and when they (the kidneys) are in a state of disorganization. The other exciting causes are excessive discharges of any kind, suppression of customary evacuations, exposure to a moist cold atmosphere, sudden repression or disappearance of certain eruptive diseases, intemperance, abuse of spirituous liquors, drinking large quantities of watery fluids, eruptive fevers (especially scarlatina and measles), and intermittents of long standing, chronic diseases which weaken the arterial and venous circulation, diarrhœa, dysentery, phthisis, gout, chlorosis, visceral diseases, excessive depletion or blood-letting; in a word, all debilitating diseases, because all diminish the circulation and favour venous congestion. The predisposing cause is a leucophlematic temperament, characterised by a pallid, bloated countenance, and want of activity or muscular energy. The proximate cause is an effusion of serum, ascribed by some to a congested condition, induced by a state approaching to sub-acute inflammation, and by others to debility.

The symptoms are swelling of the insteps or ankles in the evening, which gradually or suddenly ascends to the leg, thigh, and trunk of the body, and sooner or later there is effusion into the serous cavity of the chest or abdomen. The cellular tissue all over the body may also be infiltrated, and when that portion in the lungs is affected, there will be difficult respiration, cough, and a watery expectoration. The countenance is pale and bloated, the skin pale and dry, the urine scanty, pale, or high coloured, depositing sediments of different colours; the appetite is bad, there is insatiable thirst, costiveness and generally a small weak pulse, and great prostration of strength. In young subjects the pulse may be strong and full; and when the skin is distended it may become inflamed, tense or shining, or in debilitated subjects allows an exudation of serum through its pores; or it sometimes is partially covered with vesicles or small blisters, which burst and allow the fluid to escape—a fact that leads us to employ punctures, acupuncturations, and scarifications. There is now a lady aged 23 years under my care, who has laboured under anasarca and ascites for ten years; and in this case “the watery

fluid,” trickles down the lower extremities so profusely as to wet her stockings; and when she allows her arm to hang over the back of a chair (a position which impedes the circulation) “the water drops from the tops of her fingers.” There is no breach of the skin, which is remarkably pale.

The prognosis in dropsy is favourable, when the disease depends on causes which are easily removed; when it comes suddenly, independently of visceral disorganization, the strength being little diminished, the constitution unimpaired, the appetite tolerably good, the thirst slight, the urine moderately copious, the respiration slightly affected or natural. The prognosis is unfavourable when the disease is caused by disorganization of the liver, heart, kidneys, &c. accompanied by insatiable thirst, laborious respiration, dry skin, paucity of high, dark-coloured, or fetid urine, petechiæ, hæmorrhages from the gums, stomach, bowels, bladder, &c.

The indications of treatment are, 1st. to excite the absorption or evacuation of the effused fluid; 2nd. to prevent it from re-accumulating; 3rd. to improve and restore the general health.

To fulfil the first indication we employ the various remedies which act on those organs destined to carry off the serous part of the blood, as the kidneys, bowels, skin and lungs. We therefore exhibit such *cathartics*, as produce watery evacuations (hydragogue cathartics)—elaterium, camboge, scammony, jalap combined with supertartrate of potass (cream of tartar), croton oil, submuriate of mercury, colocynth, &c., *diuretics*—squill, digitalis, acetate, hydriodate—nitrate and supertartrate of potass, colchicum, nitrous æther, juniper, lytta, &c. &c.—*diaphoretics*, as compound powder of ipecacuanha, antimonial preparations, tepid diluents, vapour and warm baths, &c., friction, punctures, acupunctures, scarifications, iodine, and antimonial ointments, blisters, stimulating liniments, bandages, &c. Lastly, we improve the appetite, digestion, and general health, by tonics, quinine, bitter infusions, regular exercise, cold bathing, nutritious aliment, &c.

Thus we excite and cause counter-irritation—in fact, determination of blood in the extensive surfaces of the intestinal tube, the skin, the lungs, while we also excite the kidneys; we set up a number of temporary artificial disorders, we cause less blood to be sent through that portion of the exhalents which formed the dropsy; the absorbents are also excited, and act more powerfully, the increased exhalation of serum being diminished or superseded, and by the remedies mentioned we often succeed in curing the disease. But we fail when incurable disorganizations of the heart, kidneys, or liver, have induced dropsy. The organic diseases of the first two organs, when long established (and they generally come on insidiously), defy all our remedies, and so do many lesions

of the liver, though mercury and iodine will often succeed in dissipating simple hepatic engorgement, or what is generally called chronic liver disease—a fact you have repeatedly witnessed at this charity. It is also important to bear in mind, that the liver, like all other organs, may be the seat of numerous disorganizations, hydatids, concretions, cancer, fungus hæmatodes, ossification, &c., which all our resources cannot remedy.

In the enumeration of therapeutical agents I have not mentioned blood-letting or emetics, because these are not generally employed by practitioners; though the first is valuable in young plethoric subjects, who are suddenly attacked with dropsy, but is most unquestionably injurious in young or chlorotic, and in aged persons. Emetics are still more rarely administered.

It may be urged that we use depletion in hydrocephalic cases. We do before, but scarcely ever after the dropsical effusion. In the majority of dropsical patients the effusion has existed for weeks or months before we are consulted, the general health is bad, the appetite gone, and the symptoms the reverse of those which indicate the use of the depletory measures. Thus, in the case of the child aged two years, which you have repeatedly seen, hydrocephalus, according to the mother's statement, has existed since it was six weeks old; it was deprived of all power of motion, of vision, and nearly of sensation; the head measured twenty-three inches in circumference at the time of admission, and is now reduced to twenty-two inches and a quarter by the internal and external use of hydriodate of potass, calomel, rhubarb, &c., with sensation greatly improved;—in this case, I say, no judicious practitioner would propose depletory measures. But when dropsy comes on suddenly in a few hours, or in one night, when the patient is in the vigour of life, and the pulse is full and strong, depletion is a valuable remedy—that is to say, when it is employed during the existence of congestion, and while serum is being effused.

Having made these general observations on the pathology and treatment of dropsy, I shall now direct your attention to the cases of some of my patients.

Anasarca and Ascites after Scarlatina.—

A. B., aged five years, was admitted under my care, October 21st, 1834. He laboured under scarlatina a week previously, and has now general anasarca with ascites. The integuments of the scrotum and penis are very much distended and enlarged, the respiration is short and laborious; there is much cough, loss of appetite, confined bowels, and paucity of urine. He was ordered the following medicine:

Rx. Pulveris jalapæ compositi, 3j;
Hydrargyri submuriatis, gr. x;
Pulveris digitalis, } āāij;
——— scillæ, }

Pulveris antimonialis, gr. vj;

——— cinnamomi, c. gr. x.

In chartulas vi, divide quarum capiat unam mane vespereque, nisi alvus nimis soluta sit.

Rx. Potassæ acetatis, ℥j;
Aquæ destillatæ, 3 iss;
Syrupi simplicis, 3 iv.

Sit mistura, cujus capiat cochleare medium bis in die.

He was ordered imperial as a drink. He continued these medicines with decided relief for a week, the anasarca and scrotal infiltration were diminished, but not so much as was desirable.

28. He was ordered the following remedies:

Rx. Elaterii extracti, gr. j;
Hydrarg. submur., gr. xij;
P. Cinnamon. comp., ℥j.

Divide in chartulas xij., ex quibus sumatur una bis vel ter in die, nisi alvus nimis purgetur: iteretur mistura ut antea.

Nov. 4. The medicines acted powerfully on the digestive and renal evacuations, anasarca and ascites gone; no cough or difficulty of respiration; appetite very much improved.

Contr. mistura.

Habeat. pulv. jalapæ. c. ℥ss., pro re nata, hora somni.

7th. Considered by his mother quite well—powders continued every other night—discharged.

Clinical Remarks.—We have lately had several opportunities of witnessing the efficacy of the medicines prescribed for this patient, in cases of general and local dropsy (anasarca and ascites), in adults as well as children, when these complaints were not caused by diseases of the liver, kidneys, heart, or by tumours pressing on the large vessels in the abdomen. I need scarcely remind you that when organic disease of the liver, kidneys, or heart exists, or a tumour presses on the ascending cava, and prevents the return of the venous blood to the heart, by pressing on the vessels whose function it is to convey it to that organ, the peritoneum must become congested, the serous portion of the blood, which ought to be disposed of in the ordinary manner, will be effused into the cavity of the abdomen, and cause ascites or enter the cellular tissue and induce anasarca.

It is therefore a medical axiom that we cannot cure such dropsies until we remove their cause; for while this exists, the effect must continue; the maxim, “ablata causa, tollitur effectus” is therefore correct, as regards the disease under consideration. Our little patient had no disorganization of the viscera alluded to; and therefore his case was, comparatively speaking, favourable. His disease supervened on scarlatina, a frequent sequence in adults as well as in children. It is not easy to explain the cause of the frequency

of its occurrence; but it appears to me to depend on the morbid effects of scarlatina on the skin. The cuticle over the whole body may disquamate or peel off, specimens of which I now shew you; and this condition can scarcely occur without affecting the skin, which is so intimately connected with the cuticle. Be the cause what it may, every experienced practitioner knows that anasarca, with or without ascites, frequently supervenes during the convalescence after scarlatina. The super-vention of one disease on the other, may take place in a few hours, days, or weeks. I remember a singular illustration which I observed with Mr. Heath, of the New Road, an old pupil of this class, in Grays-inn-lane. A youth, aged twenty years, of a full habit, had recovered from the malignant form of scarlatina. He was convalescent for a month. The season of the year was spring. He had dined heartily at one o'clock, and after dinner went into Grays-inn Square to take a walk—the day was very cold. He returned home, (and his residence was in the immediate vicinity); at half-past two o'clock in the afternoon he was suddenly seized with general anasarca; this was immediately followed by convulsions, and I was requested to see him. I examined his stomach, lest it might be overloaded, as he had dined so recently, and found it empty. I ordered him to be bled, his head shaved, leeches to be applied to the base of the skull, both temporal arteries to be opened, his bowels to be purged with croton oil, cupping on the nape of the neck, cold applications to his head, mustard cataplasms sprinkled with warm oil of turpentine to his feet and legs, and notwithstanding all these remedies, which were employed in rapid succession, he died at two o'clock on the following morning. My friend and myself examined the body. On making the usual incision through the scalp, we were astonished at the quantity of serum, or what is popularly denominated watery effusion. It deluged the table, and was received into a vessel. The brain was highly congested, so were the lungs, but the stomach was empty. It is right to mention that the sister of this individual had previously died of scarlatina, and she had had an unusual symptom, a purulent discharge from both nostrils and ears. You know, as anatomists, that inflammation of the mucous membrane of the fauces (throat) may extend to the Schneiderian mucous membrane of the nostrils, as well as along the same kind of membrane, which lines the Eustachian tubes, all of which are continuous, and thus may produce discharges from the nose and ears.

It is stated by many writers on practice of medicine, that scarlatina is in general a mild disease, and seldom proves fatal. Scarlatina, when it affects the fauces, (*scarlatina anginosa vel cynanchina*) is often a formidable and dangerous disease; but when there is sloughing (*scarlatina maligna*, malignant scar-

latina) there are few complaints so dangerous or fatal. In either of the two last forms it frequently destroys several children in schools, or in the same family. I have frequently seen three and four children of one family, lying dead at the same time, in consequence of this disease. The mild form, or *scarlatina simplex*, seldom proves fatal. Scarlatina is so fatal, that our German brethren consider themselves entitled to great praise for having discovered what they suppose to be a preventive. This is the extract of belladonna, in proper doses, according to the different ages. Dr. Macmichael has also written in favour of this remedy. But I have not had sufficient opportunities as yet, to warrant me in arriving at a conclusion as to its efficacy. There is one thing, however, in its favour; that it can do no harm, when administered in proper doses. It was proposed by Hanhemann, in 1807, on the principle that it caused symptoms similar to scarlatina. It was exhibited by Berndt in one hundred and ninety-five cases, in 1818—19, of which fourteen only were infected; and, at a subsequent period, when he used a stronger dose, every one escaped. Koreff, professor at Berlin, exhibited the medicine on the recommendation of Soemmering, and states, that neither season nor climate appeared to diminish its preservative power. Hufeland confirms the preceding statements, (*Journ. der Practischen Heilkunde*, 1825), by declaring he has never known it to fail. Two or three grains of the extract, in an ounce of cinnamon water, was the prescription—the dose, two or three drops twice a-day, to infants under two years old, and one drop in addition for every year above that age. But to revert to our patient, A. B. aged five years. Some of you may imagine that he was not a fit subject for elaterium; you have learned this from the works on *Materia Medica*, whose authors in general quote from their predecessors, without taking the trouble of thinking for themselves. They all inculcate the erroneous doctrine—you must not prescribe elaterium for young or old persons. Their doctrine is correct, until we consider developement and physical power; but when we do, it is erroneous. You observed that our little patient was not sufficiently relieved by ordinary remedies; I therefore thought, that more powerful medicines were necessary. And what objection, I should like to inquire, is there to any medicine in proper doses, or in other words, proportioned to the different ages and physical powers? I know of none. We can subdivide the dose of any medicine like the homœopaths, to infinity. I therefore ordered elaterium for this child, contrary to the received opinion, and you have witnessed the beneficial result.

There is another point of practice which requires an explanation. The integuments of the scrotum and penis were so enormously distended, that some of you hinted to me the propriety of scarification, or acupunctu-

ration. The idea was good in theory, but in this case bad in practice; moreover, the mother would not consent to it. I declined to order any operation, because I had repeatedly seen worse cases do well, by the remedies prescribed. Moreover, Sir A. Cooper has well observed, "The best surgeon is he who performs the fewest operations." Why should we operate, if we need not? I see no valid reason. If our remedial means failed, and that there was no other alternative but an operation, then, and only then, would it be justifiable. Our patient got well by medicines, without any operation, and this was positive proof of the efficacy of the treatment. —Lastly, some of you, no doubt, are surprised at the heterogeneous nature of the powders prescribed for this child, when admitted. My answer is, that considering the innumerable varieties of constitution, or to speak scientifically, idiosyncrasies, or peculiarities of habit, much more good is to be effected by a combination like that which I prescribed, than by ordering its component parts separately. The ingredients in the powders are generally ordered in separate forms, as draughts, pills, powders, &c.—all are given at different hours of the day; all are taken into the stomach; and as there is no objection to unite them in powders, why not do so, and save the patient the annoyance of swallowing physic every hour, which few individuals relish, not even the members of our own profession, and much less children. The powders prescribed were calculated to act on the bowels, kidneys, lungs, and skin. The compound powder of jalap, with calomel, acts as a hydragogue cathartic (the former was the best remedy in dropsy, according to Cullen); the rest of the ingredients act upon the kidneys, skin, and lungs, the organs which dispose of the serous or watery parts of the blood; and thus we set up artificial irritations or diseases in these organs, whose functions are to remove the thinner parts of the blood, and consequently prevent them from being deposited in the cavity of the peritoneum, ascites (abdominal dropsy), or in the cellular tissue, which pervades all parts of the body, (anasarca or general dropsy).

Ascites supervening immediately after Parturition.—E. H. aged 21½, a thin spare habit, of a bilious temperament, unmarried, and very hysterical, was admitted under my care, at the recommendation of Mr. M'Cann, surgeon obstetrician to this charity. About six months ago she was delivered, at the full time, of an illegitimate infant, which was born alive, after a labour which continued for 24 hours. She stated, in the presence of Mr. Churchill, of Strutton Ground, a gentleman in practice, and a pupil of this dispensary, who noted her case, that immediately after delivery, her abdomen swelled to a considerable size, and did not subside until

she was admitted at this institution. When the swelling of the abdomen supervened after delivery, she complained of great thirst, paucity of urine, swelling of the legs, bad appetite, pain in the right shoulder, which she did not experience before delivery. She suffered very much from dejection and depression of spirits before her confinement, as she was illicitly pregnant, and deserted by her heartless seducer. She consulted Dr. — who told her she had dropsy. The medicines he prescribed for her purged her very violently, but did not increase her urine, and the swelling of her abdomen augmented while she was taking them. She then suffered from violent pains in the abdomen; the medicine was composed, according to her account, of a tea-spoonful of castor oil, and three drops from a very small bottle, (query, croton oil?). The pains in her abdomen became so violent as to affect her respiration, and her mother determined to call in Mr. M'Cann, of Parliament Street, who attended her four days, and then placed her under my care. When she was admitted at the dispensary, she suffered from violent diarrhoea, which defied all medicine, except a pill composed of s. cupri, gr. ij; opii gr. iij; confect. rosæ, 3 ss.—divide in pilulas xvj—capiat j, bis vel ter in die. In fact, so irritable were her bowels in consequence of the operation of the croton oil, that the diuretic medicines ordered, and which will be mentioned immediately, often purged her excessively. Purgatives were contra-indicated.

She was admitted in September last. Her symptoms then were, great debility, distinct fluctuation in the abdomen, accompanied by thirst, paucity of urine, but no anasarca of the lower extremities. She was ordered a diuretic mixture composed of hydriodate of potass, 3j, distilled water, 3vj, to be sweetened when about to be taken; two table-spoonful twice or thrice a day. She had likewise the infusion of quassia, with quinine. She continued these remedies until Nov. 28th, during which time she gradually diminished in size; and this fact she ascertained by frequent admeasurement of the abdomen, with a graduated tape, which was accurately subdivided in inches.

Nov. 28th. R. Potassæ acetatis, 3iv;
Aquæ menthæ, pip. 3vj;
Sp. æther, nitrosi, 3ij;
Tinct. opii, 3j.
Syrupi auranti, 3j;
Dosis 3ss, ter in die.

R. Hydriodatis potassæ, ʒj;
Adipis prepar., 3j.

A drachm of this ointment was to be rubbed, night and morning, over the surface of the abdomen. She continued these remedies until Jan. 9th, 1836, when she reported herself, in the presence of Mr. Churchill and Mr. Dawson, of her usual size when in health. On being questioned as to the grounds on which she arrived at this conclu-

sion, she stated, that the stays which she had by her, and when in health, now fitted her exactly as before her illness.

Nevertheless, there was evident fluctuation in the abdomen, which was ascertained by Mr. Churchill and Mr. Dawson, as well as myself; and I therefore advised her to continue on the books, until I pronounced her perfectly cured. Jan. 28th.—There is still fluctuation. She thinks herself well, but I have advised her to continue her medicine. She is wonderfully improved, her appetite and spirits are good, her bowels and menstruation regular.

Clinical remarks. This was a very singular case—dropsy, supervening in a young woman in the prime of life immediately after a first parturition. The great irritability of the bowels was most probably induced by the croton oil. The diarrhoea was restrained by *s. cupri*, with opium only. I should have stated that ordinary astringents had previously failed.

Mr. Churchill recollects a case of blue cholera to which he called me, and in which the rice-coloured evacuations from the bowels were restrained by *s. cupri*. The hydriodate of potass, was prescribed in mixture as a diuretic, as it had proved effectual in dropsy caused by chronic liver disease in the practices of my much respected friends, Dr. Blake of Nottingham, and Mr. Hughes of Holborn.—*Land. Med. and Surg. Jour.*, vol. v, 1834.

An ointment containing this medicine was rubbed over the region of the liver, and the surface of the enlarged abdomen, to excite or stimulate the absorbents.

There was pain in the right shoulder, which most probably arose from functional or structural derangement of the liver. Was her dropsy caused by mental dejection or by hepatic disorder or disease? It is extremely difficult to answer this question. In fine, both these cases are worthy of your recollection and reflection. I shall detail other interesting cases at our next meeting.

STATE OF MEDICINE AT NEWCASTLE-UPON-TYNE.

To the Editor of the Original Medical and Surgical Journal.

SIR—In my letter to you (dated the 25th of December, 1834), on the Medical Institutions of Newcastle-upon-Tyne, it is stated, that “no instruction, in the form of lectures, is given by the physicians, nor are any regular reports made at their visits to the wards.” The accuracy of this statement is unquestioned; I shall consequently make a few observations on this fact. It may in the first place be asked, Why is no clinical instruction given by the physicians in so excellent an institution? This question has been variously answered, as for example, the physicians cannot devote a sufficient portion of time to such duty; there are too few pupils to render it worth

their while to do it; and lastly, we are told that if it were done, it would be at the expense of the comfort of the patients. In regard to the first of these three reasons (if so they may be called), it is too ridiculous to require comment, farther than simply comparing the duties of metropolitan and provincial physicians in full practice. In reply to the second reason, the *paucity of pupils*, I would simply ask, whence does this arise? Is it that the number of medical pupils in the district is small? No, the opposite of this can be attested by every practitioner in the district. That a small proportion of the pupils attend the infirmary I shall not attempt to deny: I know the fact, and by many I have been told, “that if regular instruction were to be had at the hospital they would attend it; but as it is in regard to the physicians, and was a very short time ago with the surgeons also, they know that little benefit can be derived from such attendance.” Here then I conceive we have the “proximate cause.” Let the physicians deliver lectures, and they will very soon find that such lectures will be attended. In regard to the *objection* that such a course of instruction interferes with the comfort of the patients, no one can deny that there are cases in which delicacy may forbid it; but it will be conceded that these are only to be regarded as exceptions; and by those who have seen clinical tuition in its most perfect form, it will be allowed that it actually contributes to, instead of interfering with the interests of the patients. Let us however even admit that it does interfere with the comfort of the inmates of an hospital, but let us contemplate the immense advantages derived from it; by this means we shall be enabled to decide whether or not a great benefit to society is to be sacrificed, because it *interferes* with the *prejudices* of a few. Let us now turn from the physicians who do not lecture, to the surgeons who do. There are, as formerly stated, four surgeons, by whom alternately two lectures are delivered in the week. In other words, A. lectures to day, and does not again lecture till this day fortnight. Let us for one moment reflect upon this arrangement, to be convinced of its absurdity. The only advantage which it appears to possess is, that (in the absence of full reports of visits) the fortnight which intervenes allows the pupil to forget what he has heard, or perhaps prepares his mind for the reception of *new information*. This may probably be denied by those who imagine that clinical surgical instruction consists in telling the pupil that a leg is cut off because it must be cut off; but if the object of clinical instruction be to explain to the pupil the causes of the phenomena which disease presents, to enable him to distinguish cause from effect, and to trace the latter to its source; if it be the object of clinical instruction to point out the means by which morbid action may be altered, and in what manner such alteration

is produced, to explain the reasons why one remedy of a particular class is preferable to another, or why an operation may or may not be performed with a hope of success, then will it also be evident that connection is not less important to the clinical student, than it is to him who has just commenced the study of the elements of medicine. I shall now allude to the circumstance connected with clinical instruction, which appears to favour the idea of the patients' comfort being involved, viz. to the reports made at visits. In the present state of things, the practitioner proposes a series of questions to his patient, to which of course he receives answers, and whilst doing so the bed of the patient is surrounded (or partially so) by pupils. Now if one of the individuals present notes down the answers, I am quite at a loss to understand how such a proceeding can in any way injure the patient, although it is obvious that such notes would be highly useful both to the practitioner and pupil, and must in my humble opinion form the base of the lectures subsequently delivered. In fine, until some better arguments can be brought forward to justify such defective execution of the important duties of hospital physicians and surgeons, it appears that such medical officers should either fully perform the honourable and responsible task imposed upon them, or that the governors of such institutions make it a *sine qua non* in all future appointments.

It is generally admitted that it is easy to find fault with that which already exists, and that this may be done by persons incapable of either suggesting or executing any thing so good. Now, sir, in the present case, I imagine that the disease being exposed to view, and not being characterized by any symptoms indicative of absolute and intractable organic lesion, and although it may to a certain degree have assumed the chronic form, it seems to me not to require any very profound knowledge either of pathology or therapeutics to ensure a successful termination of the case. The disease then being *functional* rather than organic, there appears no necessity either for excision or amputation. Let us then consider by what means we may best obviate this functional derangement. The principal indication appears to be to overcome, in the first instance, a slight degree of congestion, and the second is obviously to be fulfilled by the judicious exhibition of stimulants. To speak seriously, that which I have termed congestion is prejudice, which too frequently induces those who entertain it to regard every thing new as an innovation. That it is often difficult to overcome prejudice every one must admit. But let this once be effected and we have not much to contend against. For a stimulus to increased exertions, the medical officers of the Newcastle Infirmary have only to look around them at other provincial hospitals, to find that they have been outstripped in the

race, the termination of which is professional fame and increased public confidence.

I remain, Sir,

Your most obedient servant,

GEORGE FIFE.

January 29, 1836.

54, Eldon-street, Newcastle-upon-Tyne.

A NEW PRACTICAL FORMULARY

OF HOSPITALS, OR A

Collection of Formulæ of the Civil and Military Hospitals of France, Germany, Italy, Great Britain and Ireland, &c., containing the Indication of the Doses in which simple Substances, magistral and officinal Preparations of the Codex are administered, the use of New Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M. D., and P. VAVASSEUR, M. D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M. D. &c. &c.

(Continued from p. 820, Vol. VI.)

TURPENTINE.

A very powerful stimulant, which, besides its action on the general economy, exerts a special influence on the genito-urinary organs and mucous membranes. It is employed with advantage in the advanced stage of catarrh of the bladder, and in other diseases of the urinary apparatus, in chronic pulmonary catarrh, mucous diarrhoea, gout and rheumatism, &c. It is applied externally to wounds and ulcers.

INTERNALLY. Gr. x—3j two or three times a day, in pills or emulsion.

Terebinthinate Emulsion. H. of Mont.

Rx. Terebinthinæ chiæ,
Sp. vin. lavatæ, ʒ iss;
Vitell. ovi unius.

Misce et adde gradatim.

Aquæ menthæ, ʒ xij.

The dose is ʒ ss—j, in a glass of sugar and water fasting, or two or three hours after dinner.

It is used with benefit in diseases of the kidney or bladder.

Astringent Mixture. H. of Germ.

Rx. Terebinthinæ chiæ,
Balsami copaibæ,
Olei succini, āā ʒ iv.

The dose is from mxxx—3j three or four times a day. In certain cases of nocturnal pollutions and blennorrhagia. [The counter-irritation or induction of a new action in the genito-urinary organs will be advantageous, provided the usual malpractice is avoided. T.]

Pills of Turpentine. H. of Lyons.

Rx. Terebinthinæ, ʒ j;
Extracti rhei, ʒ iss;
Camphoræ, ʒ j.

Fiat massa in pilulas gr. iv, dividenda quarum deglutiat tres ter in die.

In leucorrhœa and blennorrhagia.

[Pills of Turpentine with Rhubarb. (Cline.)

Rx. Terebinthinæ, 3 ij;
Pulveris rhei, 3 j.

Divide in pilulas xxxvj, capiat seger, iij
his indie.

In blenorragia, gleet (blenorrhœa), and dis-
eases of the prostate gland.

[Turpentine and lytta are combined in
appropriate doses in cases of impotence,
catarrh, and paralysis of the bladder, and
leucorrhœa. T.]

Anthelmintic Pills. H. of Germ.

Rx. Terebinthinæ, 3 j;
Resinæ jalapæ, 3 ss;
Ext. hyosciami, gr. iv;
Hyd. submur. gr. viij.

Distribue in pilulas xij—dentur iv tertiis
horis.

In tape-worm.

EXTERNALLY. In clysters—3 i—iv. It
is also applied to wounds and ulcers; [but
generally with bad effects. It is a popular
practice to apply Venice turpentine to re-
cent wounds and ulcers in this country; but
its stimulating power aggravates these dis-
eases. If used in cases of long standing or
chronic ulcerations, the remedy is often be-
neficial, provided it is ordered by medical
practitioners, who alone can select the pro-
per cases. T.]

Resolvent Mixture. (Durande.)

Rx. Essentia terebinth., 3 ss;
Sp. ætheris sulphur, 3 ias.

Dose mxx—3 j in whey, in cases of bili-
ary calculi or gall-stones and hepatic colic.

[Biliary calculi or gall-stones cause in-
tense pain and spasm, which the sedative
preparations of opium or other narcotics
may relieve; but all solvent remedies are
perfectly useless, as they cannot pass from
the duodenum into the gall ducts. I have
lately had a female patient under my care
at the Western Dispensary, who was labour-
ing under this disease, and suffered from ex-
cruciating agony, though all the usual re-
medies were freely employed. She went
into the country, was recommended mustard
seed, took it in tea-spoonful doses several
times a day, and after some time passed,
according to her statement, at least a hun-
dred gall-stones. She did not preserve one
of them; she ascribed her cure to the mus-
tard seed, in the presence of several students,
though her remedy could not have had any
beneficial effect. Hoffman states, in his
Practice of Medicine, that gall-stones may
be evacuated in great numbers, and that
they have been set in rings and signets.
They have passed into the transverse colon
and peritoneum, and often destroy life.
There is no remedy which can dissolve or
dislodge them. A lady aged 25 years, a
patient of mine, passed a vast number of
them by the bowels, and a sandy substance
of the same colour from the bladder. Cases
are on record in which these substances were
evacuated through the anterior parietes of
the abdomen. T.]

The terebinthinate enema is used in this
country and on the Continent of Europe in
tympanites, lumbago, and ascarides.

Terebinthinate Clyster. H. of Germ.

Rx. Terebinthinæ, 3 j.

Tere cum vitello ovi et adde,

Theriacæ, 3 iv;

Lactis calidi, 3 iv.

Van Swieten employed this lavement to
allay colic and tenesmus which accompany
colliquotive diarrhœa in phthical subjects.

ESSENTIAL OIL OF TURPENTINE.

A purgative in large doses, in small
doses the same as the last remedy. It is
employed with advantage in the treatment
of neuralgia and debility of the genito-uri-
nary organs. It is also used in tœnia. Ex-
ternally it is employed as a stimulant in
neuralgia, lumbago, sciatica, chronic tu-
mours and ulcers, &c.

[It is a stimulant, cathartic, diuretic, an-
thelmintic, astringent in small doses, and a
rubefacient. It has been used with good
effect in epilepsy, in rheumatism, gout, and
sciatica (Geo. Cheyne), in gout of the sto-
mach (Mason Good), in puerperal fever
(Brenan), in iritis (Hugh Carmichael), in
yellow fever (Chapman), in numerous dis-
eases (Copland), in burns, purpura hæmorr-
hagica (Whitlock Nichol), to suppress mer-
curial ptyalism (Geddings), to allay nausea
and vomiting in the first months of preg-
nancy (Dewees), in epilepsy, tympanites in
the last stage of fever and in hysteria, in the
low delirium of fever, accompanied by a
congested state of the intestinal mucous
membrane, in convulsions caused by intes-
tinal irritation in infants (Graves' Lond. Med.
and Sur. Journ., vols. ii and iii, 1832-33),
in pulmonary complaints as a rubifacient in
adults and children, in pneumonia, pleuritis,
bronchitis, hooping cough, asthma, croup,
phthisis, &c. (Little—Dublin Med. Journ.,
v. 5, 1834), while I have substituted warm
oil of turpentine during the last seven
years for blisters in all deep seated inflam-
mations in the head, chest, or abdomen,
because too much time was lost in such
diseases in waiting twelve or twenty-four
hours, for the doubtful effect of blisters,
which, from adulteration, very often fail.
In cerebritis, hydrocephalus, pneumonia,
enteritis, peritonitis, hepatitis, &c. &c., the
idea of waiting several hours for the counter-
irritating effects of a blister, appeared to me an
extremely inert and unjustifiable practice,
for in such cases the sooner counter-irritation
is effected the better. I have already re-
commended this practice in mine, the last
edition, of Hooper's Physicians' Vademecum,
1833, and I have inculcated the propriety of
employing the remedy in my lectures on
the practice of medicine since 1828—a fact
known to at least five hundred students,
many of whom are qualified practitioners.
Dr. Copland claims the merit of having
first used and recommended oil of turpen-
tine both internally and externally in near

ly all the diseases mentioned in this parenthesis; but I, for one, was not aware of it. The learned author of the Dictionary of Practical Medicine published a paper on the use of oil of turpentine some years since in the London Medical and Physical Journal; but there are many diseases now enumerated omitted in that essay. He, undoubtedly, was one of the first, if not the very first British writer, who introduced the remedy under consideration to the notice of the profession in a vast number of diseases; but certainly not in all, in which it is now so beneficially employed. He has also the merit of having proposed the addition of tincture of capsicum to correct the nauseating effects of oil of turpentine on the stomach. Perhaps the best mode of exhibiting this medicine is in emulsion with mucilage and yolk of egg. T.]

INTERNALLY. As a general stimulant, ℞—xv in honey or emulsion.

As an anti-neuralgic, from 3ss—j in divided doses.

As an anthelmintic or cathartic, from 3s—ij in emulsion, combined with castor oil or in sweetened milk.

Terebinthine Mixture. H. Dieu.

℞. Olei terebinthinæ, 3ij;
Mellis rosæ, 3iv.

The dose is a table-spoonful three times a-day.

Employed by M. Recamier in the different forms of neuralgia. The disagreeable effects of this mixture are obviated by the following:

Terebinthine Looch. H. Dieu.

℞. Olei terebinthinæ, 3iij;
Syrupi menthæ, 3ij;
——aurantii,
——ætheris, āā 3j;
Tincturæ canellæ, 3ss;
Vitellum, ovi, j.

Dosis 3ss. ter in die.

When this medicine induces vomiting, a drachm of laudanum is added.

Anthelmintic Draught. (Cadet).

℞. Olei terebinthinæ, 3ij;
Mellis despumati, 3vj;
Aque menthæ, 3iij.

This is divided into three doses, to be taken in one day, in cases of tapeworm.

[Dr. Brenan prescribed 3ss—3ij in what he termed puerperal fever; and Dr. Payne, of Nottingham, writes most favourably of its efficacy. In my opinion both employed it in puerperal peritonitis, and not in uterine phlebitis, which is malignant puerperal fever (Tonnellé, Dance, Lee, &c.), in which calomel used in scruple doses combined with morphia and camphor administered every hour, with free mercurial unction of the axillæ and groins, are the only effectual remedies. Oil of turpentine, 3ij—iv with 3iv and 3j of castor oil in the form of emulsion composed of yolk of egg and mucilage of acacia, is the best remedy in peritonitis, but is ineffectual in malignant puerperal

fever, so far as my observation extends. The external use of warm turpentine as a counter-irritant in abdominal or uterine inflammation is extremely valuable. The medicine should be warmed, and rubbed with a piece of flannel over a small portion of the skin, which will be irritated in a minute or two, and then the medicine ought to be discontinued. T.]

Terebinthine Clyster. H. Dieu.

℞. Olei terebinthinæ, 3j;
Vitellum ovi, 3j;
Decocti papaveris, 3viij.

In lumbar neuralgia and ascarides.

Terebinthine Linct. H. Dieu.

℞. Olei terebinthinæ, 3j;
——camomeli, 3ij;
Tinct. opii, 3j.

In cases of neuralgia in which the sufferers cannot bear the internal use of turpentine.

Anticonvulsive Mixture. (Gravès.)

℞. Olei terebinthinæ, 3j;
——ricini, 3iv;
Syrupi papav. alb., 3j;
Mucilaginis acaciæ,
Aque fœniculi, āā 3ij;

Dosis 3j tertiis horis.

In convulsions of infants from three months upwards, when caused by intestinal irritation, or congestion of the gastro-intestinal membrane.

[I have lately had a case of sciatica under my care at the Hospital which was supposed to be caused by neuritis, but it yielded to the internal use of turpentine, after the ordinary remedies had failed. Several gentlemen now attending the medical practice of the institution witnessed this case.

Dr. Edwards and Dr. Vavasseur describe Burgundy and black pitch as external applications, but they are so well known that they need not be introduced. T.]

Antistatalagogue Gargle. (Geddings.)

℞. Mucilaginis acaciæ, 3viij;
Olei terebinthinæ, 3ij.

[I have found this very effectual, but it may fail. T.]

BALSAM OF COPAIBA.

A very energetic stimulant, which acts chiefly on the mucous membranes. It is used with advantage in chronic catarrhs, and certain affections, not inflammatory, of the lungs. Its most common use is in gonorrhœa. It is administered in obstinate leucorrhœa, watery diarrhœa, caused by atony of the intestines, &c.

INTERNALLY. Gut. x ad xx, as a stimulant, two or three times a day, with sugar, or in an emulsive potion.

3ij ad iv, and even more, progressively, in gonorrhœa, leucorrhœa, &c., either in a potion or in pill.

Astringent Potion of Chopart.

Rx. Balsami copaibæ,
Aque destillatæ menthæ,
Alcoholis,
Syrupi capilli veneris, ā ā ʒ ij;
Aque aurantii, ʒ j;
Acidi nitrici, ʒ ij.

Fiat mistura ejus sumat cochl. mag. ter in die.

Much used in the treatment of gonorrhœa.

The *Potion de copahu composée* of the H. de la Ch. differs only from the preceding, in containing two ounces of orange-flower water.

The *Potion astringente* of the H. de Ven, differs more from that of Chopart than the preceding one, but acts in a similar manner. It is composed of mint water, orange-flower water, syrup of marshmallows, and of the balsam of copaiba, ā ā sixteen parts; of gum arabic and nitric acid, ā ā one part.

Balsamic Potion of Fuller.

Rx. Balsam. copaibæ,
Syrupi toluiferæ, ā ā ʒ ij;
Vitelli ovi, No. j;
Vini albi, ʒ iv.

Fiat mistura de qua capiat cochlearia tria magna in die.

In the same cases as the preceding mixtures.

Syrup of the Balsam of Copaiba. H. of Ger.

Rx. Mucilaginis gummi acaciæ, q. s.;
tere cum,
Balsami copaibæ, ʒ j ss,
Adde gradatim,
Syrupi, simplicis, ʒ xvij.

Fiat syrupus ejus sumat æger cochl. min. quater in die.

In gonorrhœa and chronic diseases of the chest.

Pills used in Bleorrhœgia. Hôt. D.

Rx. Balsami copaibæ, ʒ ij;
Hydrargyri submuriatis, gr. xvij;
Sanguinis draconis, ʒ j;
Conservæ rosæ, ʒ j.

Divide in pilulas granorum, vi; quarum, ij; vel, iij; capiendæ mane nocte quæ.

Antigonorrhœal Pills. H. of Germ.

Rx. Balsami copaibæ,
Magnesiæ, ā ā p. e.

Distribue in pilulas granorum x; e quibus capiat, ij; vel, iv; ter in die.

Antigonorrhœal Boluses. H. Militaires.

Rx. Balsami copaibæ,
Conservæ rosæ,
Pulveris glycyrrhizæ, ā ā ʒ j.

In bolos sex divide quorum, ij; vel, iij; capiendi quotidie.

The *Bols astringent* of the H. des Vén do not differ much from the preceding ones. They are composed of— ʒ ij of the balsam copaiba, ʒ j of gum arabic, and a sufficient quantity of pulverized liquorice. This mass is divided into xx boluses, of which half are

taken in the morning, and the other part in the evening, in chronic gonorrhœa.

Balsamic Boluses. H. of Italy.

Rx. Balsami copaibæ,
Pulveris gentianæ, ʒ j;
— zedoariæ, āā gr. xx;
Syrupi simplicis, q. s.

Misce.

Divide in bolos xvij, e quibus duo sumendi ter in die.

In treating gonorrhœa, &c.

Antigonorrhœal Opiate. (Swediaur).

Rx. Mucilaginis gummi acaciæ, q. s.
Balsami copaibæ, ʒ vi;
Sacchari, ʒ vi;
Syrupi simplicis, q. s.

Misce.

Cochlearia duo vel quatuor adhibenda mane nocteque.

Anthelmintic Mixture. H. of America.

Rx. Balsami copaibæ, ʒ ij;
Sodæ subcarbonatis, ʒ j;
Tincturæ opii, gut. lx;
Emulsionis simplicis, ʒ iv.

Fiat mistura, ejus sumat cochleare magnum, tertiâ vel quarta horâ.

In vermicular affections.

EXTERNALLY.

Enema of the Balsam of Copaiba. H. de Perfect.

Rx. Balsami copaibæ, ʒ iv;
Misce cum vitello ovi et adde,
Camphoræ, gr. iv;
Extracti opii, gr. j;
Aque gummi, ʒ iv.

Fiat enema.

Employed with advantage to stop gonorrhœal discharges, either acute or chronic.

Balsam Injection. H. of Germ.

Rx. Balsami copaibæ, ʒ iv;
Vitelli oni, q. s.;
Aque calcis, ʒ vj;
Mellis rosæ, ʒ iij.

Fiat injectio.

Used in the treatment of fistulous ulcers.

BALSAM OF PERU.

An energetic stimulant, employed in chronic pulmonary catarrh and phthisis. It is used in the same diseases as the resins of which we are about to speak.

INTERNALLY. Gr. xij; ʒ j; in pills or emulsion.

Mixture of Werlhof.

Rx. Balsam. Peruv. ʒ ij;
Vitell. ovorum, ij;
Tere simul et adde,
Extracti cinchonæ, ʒ iv;
Mellis rosæ, ʒ vj;

Dosis, ʒ ss ter in die.

In chronic pulmonary catarrh.

Balsamic Emulsion. H. of Germ.

Rx. Balsam Peruvian., 3j;
 Olei amygdalar., 3iss;
 Pulveris acaciæ, 3ij;
 Tere simul et adde,
 Aquæ rosæ, 3j.
 Sumat dimidiam, bis in die.

Balsamic Looch. H. of Germ.

Rx. Balsam. Peruv., 3j;
 Spermat. ceti, 3ij;
 Solve in vitello ovi et adde,
 Syrupi acaciæ, 3ij.
 Dosis 3ss. 3, 4, in die.

Acoustic Injection. (Alibert.)

Rx. Balsam. Peruv. 3ij;
 Tinet. moschi, m iv;
 Essentiæ rosæ, m j;
 Decocti hyperici perf. 3xx.

Injiciatur in aurem, q. s. hujus bis in die.

In deafness.

(Another.)

[Rx. Fellis bovis, 3iij;
 Balsam Peruv., 3j.

Hujus liquoris, quantum cavi, capi potest injiciatur in aurem affectam supinam; ac detineatur aliquot minuta, dein aure prona rursus emittatur: iteretur operatio bis vel ter in die.

In foetid purulent discharges from the ear. T.]

BALSAM OF TOLU.

A powerful stimulant like the last. It is employed in similar cases, but more frequently. It is also used to perfume pectoral and tonic medicines.

INTERNALLY. Gr. x—3ss, in pills, electuary, or in emulsion.

Tincture. P. 3i—ij.

Syrup. P. 3ij—3j in a draught.

Balsamic Mixture. H. of Italy.

Rx. Syrupi tolutani, 3j;
 Mucilag. acaciæ, 3viij;
 Olei amygdalarum, 3iss.

Dosis, 4ta pars bis vel ter de die.

In pulmonary catarrh, blennorrhœa (gleet) blennorrhagia (gonorrhœa).

BALSAM OF MECCA.

This is similar to the preceding, and is seldom employed.

Astringent Pills.

Rx. Balsam Meccæ, m. viij;
 Opti pulveris, gr. j;
 Terebinthinæ chiæ, q. s.

In pilulas duas forma, capiat unam mane nocteque.

In leucorrhœa and blennorrhœa.

MYRRH.

In small doses stomachic and tonic; in large doses a powerful stimulant. It is employed in chlorosis, atonic affections of the digestive organs, pulmonary catarrh, &c.

It is generally united with tonics and chalybeates. Externally it is used in gangrenous angina, in chronic ulcers, in scorbutic relaxation of the gums, and caries of the bones.

INTERNALLY. In powder. Gr. x—3j.

Watery extract. Gr. v—x in pills.

Tincture. P. mxx—xxx in a draught.

Compound Powder of Myrrh. H. of Germ.

Rx. Myrrhæ pulv.,
 Opoponacis, aa 3ij;
 Sagapeni,
 Castorei, aa 3j;
 Olei menth. pip.,
 —rutæ, aa q. s.

In chartulas xxxvj divide, ex quibus capiat unam mane vespereque.

Emmenagogue.

Pills of Myrrh and Henbane.

Rx. Extracti myrrhæ, 3iss;
 —hyosciami,
 Pulveris scillæ, aa 3ss;
 Aquæ, q. s.

Fiat massa in pilulas xxx dividenda, quarum capiat æger duas vel tres quotidie.

[Some British practitioners employ these pills to promote expectoration in chronic pulmonary catarrh. T.]

Detersive Injection. H. of Italy.

Rx. Decoti hordei, Oij;
 Tincturæ myrrhæ, 3j.

In chronic coryza, accompanied by an abundant discharge of mucus from the frontal sinus; chronic ulcerations of the bladder, obstinate gonorrhœa. In the last disease, 3j of acetate of lead, and 3ss of opium is added to 3viij.

Ointment of Myrrh. H. of Germ.

Rx. Pulveris myrrhæ,
 Spermat. ceti, aa 3ij;
 Vitellos ovorum, No. ij;
 Butyri recentis, 3ij;
 Balsam Peruv., 3ss.

This ointment is employed by the German physicians with a view to remove the cicatrices or scars caused by smallpox.

[The preparation of myrrh prescribed by the pharmacopœias of this kingdom are valuable remedies in the diseases for which they are ordered. T.]

(To be continued.)

The Dublin Journal of Medical and Chemical Science, exhibiting a Comprehensive View of Medicine, Surgery, Chemistry, and the Collateral Sciences. No. XVIII. Vol. VI. January, 1835.

THE present number of the periodical before us contains six original communications, three reviews, and the usual quantity of scientific miscellaneous matter. The

first paper is by our valued correspondent, Mr. Ingleby, of Birmingham, entitled, *Illustrations in Midwifery, embracing the Obscure Characters of Pregnancy, the Signs of Death of the Ovum.* The paper is presented through Dr. Montgomery, who has written so ably on the subject. The author divides his remarks into fourteen sections, and has very ably described the difficult diagnosis of utero-gestation in many cases in which the symptoms are obscure. His communication occupies thirty-five pages. Want of space prevents us from noticing this elaborate paper.

The second article is on the *Theoretical Constitution of the Ethers*, by R. J. Kane, Esq. The object of the writer is to shew that he had anticipated Berzelius and Leibig in discovering the constitution of the ethers. He published his views in our *Dublin Contemporary*, Jan. 1833, vol. ii. Berzelius published in the same year, and Leibig in Feb. 1834. Mr. K. republishes his original paper, which we brought before our readers at the period of its original publication.

The next paper is by Dr. Griffin—What are the Principles which should be kept in View in the Treatment of Enteritis? The author cites many standard works, and has compiled a good practical paper.

Dr. Churchill has contributed some interesting cases of uterine inflammation.

Dr. Mateer follows with observations on the injurious effects of salt on the animal system. The author thinks it a frequent cause of diseases in the viscera of the chest and abdomen, adduces sea-scurvy and purpura hæmorrhagia in illustration of his doctrine; and, according to the editor, the profession in Dublin entertain the same opinions. We cannot, however, help remarking, that the attributing the dyspeptic and abdominal disorders of the poor to the excessive use of salt is a position which few will grant. We are ready to admit that the excessive use of salt will produce a debilitated state of the body, but not a moderate use of it.

The last paper is the history of a case of *Cæsarean section* in consequence of the presence of an abdominal tumour, by Dr. Montgomery. This is an instructive case, and we shall notice it fully at an early opportunity.

An Exposition of the Nature, Treatment, and Prevention of continued Fever. By Henry M'Cormac, M.D., Belfast. 8vo., pp. 202. London, Longman and Co. 1835.

THE author informs us that he has observed fevers in different quarters of the globe, and has been physician to a fever hospital and dispensary for some years. His object is to add his contributions to the annals of medicine. He has quoted a vast number of the eminent writers on fever of the last and present century, arranged their opinions in regular order, and on the whole amassed all the information which is known upon the subject. We strongly recommend this work to our readers. It contains a vast deal of knowledge in a condensed yet comprehensive form. We shall perhaps at some future time enable our readers to judge of the merits of this production.

IMPORTANCE OF OBSTETRICS—CULPABILITY OF IGNORANCE IN THIS DEPARTMENT.

THERE is no department of the healing art which requires a greater extent of scientific knowledge than midwifery; none which affords a wider range of phenomena for the deduction of pathological principles, or more frequent opportunities for their application; and none which better exercises the sagacity, firmness, and presence of mind characteristic of an able practitioner. Without a sufficient acquaintance with this branch, no physician or surgeon can be properly qualified for the practice of his profession. How, for instance, is the physician to deal with disorders connected with the gravid and puerperal states, if he be not familiar with the physiological peculiarities of these states, and their influence on the phenomena of disease? How is the surgeon to form a judgment on many obscure cases of abdominal dis-

case which simulate pregnancy, unless he be familiar, by constant habit, with the signs diagnostic of the latter? It will, perhaps, be answered, that in doubtful cases other practitioners well skilled in obstetrics may be called into consultation. But on this we would observe, that there is frequently no doubt in the mind of the uninformed practitioner till it becomes clear to himself and everybody else that he has committed an egregious blunder, which may be farcical or tragical, according to circumstances. For example, a *well-marked* case of peritonitis resolves itself into one of parturition, and the embodied phlegmasia comes forth in semblance of a lusty boy, roaring "blockhead" in the ears of the astounded son of Æsculapius! This would be nothing but an excellent joke, allusions to which, however, might not be particularly gratifying to the Doctor; but suppose another case—a surgeon performs the operation of *paracentesis abdominis*, and thrusts his trocar into the contents of a gravid uterus, thus, very probably, sacrificing two lives at once to his own criminal incapacity; this is not an imaginary occurrence—it has actually taken place, and is only mentioned here as one of the many instances in which the obstetrical ignorance of a surgeon may prove fatal to his patient. But let us take the question as stated by the advocates of *subdivision*. The physician or surgeon ignorant of midwifery is invaded by timely misgivings, and calls a professed obstetrician to his aid; if the latter be a well-informed man, conversant with every branch of medicine, his interference may be highly advantageous to the patient, while the necessity for it must reflect severely on the incompetency of his *confrere*; but if the obstetrician be as exclusive in his own branch as the other practitioner is in his, what sort of judgment or practice is likely to spring from this coalition of mutual ignorance?

Again, let us suppose the anti-obstetrical doctor or surgeon placed in a situation where no accoucheur is to be had; suppose, for instance, a woman to be taken in labour during a voyage, and her case to be such as absolutely to demand the interference of art; there is a physician or surgeon on board, who knows nothing of midwifery; well—this poor woman must die because there is no amphibious Doctor Slop resident in the midst of the Atlantic or Pacific! What would be the impression on the minds of all on board, if a medical practitioner, no matter of what denomination, was to decline interfering? Unquestionably that he was either an ignorant or a barbarian. What would be his own impression, if he undertook the case, and the patient died in consequence of his want of skill? Why, then he would indeed have the satisfaction of knowing that he had done his best; but he would also have the misery of knowing that the life of a fellow-creature had been lost through his own disgraceful ignorance. What a reflection for a man of "high moral feeling!" Yet, with such indisputable truths as these before their eyes, the Fellows of the London College of Physicians pretend to think the practice of midwifery degrading to themselves, however eligible it be for *licentiates*—who, of course, stand so low that further degradation is impossible. The pure surgeons are of the same mind: they leave midwifery to subordinates, who are already contaminated by a knowledge of physic. We beg to be understood as speaking generically, not individually; we hope and believe that there are many, in each of these classes, too enlightened and too conscientious to give in to so stupid and inhuman a prejudice.

But, after all, what is the real secret of the contempt which the *fellows* and the *pures* bear to midwifery? We will illustrate the matter by a reference to a parallel case in history. In the darkest

of the dark ages, men of rank thought it beneath them ever to put pen to paper; they would not even sign their names to any document whatsoever. Why? Because they could not write, and were too lazy to learn. We leave it to the reader's sagacity to make the application to the modern aristocracy of our profession.

Degrading! It is no degradation to the *fellow* to dance attendance on the silliest whims of a fanciful coxcomb; it is no degradation to condole with a wealthy glutton on the effects of his brutal intemperance; but it is a degradation to watch over the safety of the most interesting part of the creation, at a time always of severe suffering, and occasionally of great danger—if it be so, may we ever remain among the dishonoured!

We by no means wish to contend against the utility of certain practitioners addioting themselves more especially to midwifery; but we do contend that every practitioner who means to understand his profession, must, in the early part of his career, attend sufficiently to the study and practice of this department, to place at his command the extensive materials for scientific reasoning which it affords, and to render him fit for the conduct of such obstetrical cases as may unexpectedly fall in his way.

—o—

THE PORTSMOUTH CHOLERA GAZETTE.

THE laceration which we lately inflicted on the voracious chronicler of cholera at Portsmouth, a disease which never existed there at the period alleged, has led our opponents, under their writhings, to occupy seven pages of their splendid production in a low vulgar tirade of personalities against the Editor of this Journal. This scurrility is beneath notice. Every man of education and gentlemanly habits will despise it. But amidst this heap of rubbish, is a reiteration of a number of unblushing falsehoods, with respect to the late proprietorship of this Journal; and these we must refute for the tenth time. When men are so unprincipled as to publish falsehoods again and again, they might impose on some, who may accidentally see their assertions for the first time, more especially when their vehicle of slan-

der is distributed among several members of the profession, who never look at it or peruse it, unless sent gratuitously. It is for this reason only that we reply; because our personal feeling towards such retailers of falsehoods compels us to look upon them with contemptuous indifference. We laugh at and pity their personalities. The unfortunate hirelings who do the dirty work of the Portsmouth Cholera Gazette, and who are so unknown and insignificant as to conceal their names, a subterfuge always adopted by persons who are fearful of consequences, unblushingly assert that Dr. Ryan was not the original proprietor of the London Medical and Surgical Journal. We have already proved this was an impudent, bare-faced falsehood. Two of "the literary scavengers," as well as the writer of the article, who were employed by Dr. Ryan and his pupils last year, as reporters, well know the above assertion to be a lie. Behold the proofs!

It is well known to the reading part of the profession, that Dr. Ryan edited the London Medical and Surgical Journal, of which he was proprietor from 1829 to 1831, during which period, Mr. Renshaw was then clerk or shopman, and Mr. Rush apprentice to Mr. Underwood, late medical bookseller in Fleet Street. When Renshaw and Rush commenced business in the latter end of 1831, they had no more claim to, or connexion with this Journal, than "the man in the moon!" Dr. Ryan appointed them his publishers, though a bookseller, infinitely better known, and infinitely more respectable than they, repeatedly solicited the office. But reasons which need not be stated, induced Dr. Ryan to employ Messrs. Renshaw and Rush. He admitted them partners, in 1832, and now they have the unparalleled impudence to command their penny-a-line men to write—they were the original proprietors of this Journal—and designate this, the original, a pseudo journal. Dr. Graves and Dr. Stokes are also of this opinion, because Mr. Swift, their reporter, (who spent hours, on different days, with Dr. Ryan's near relatives in Dublin, in advising them of all things to induce Dr. R. to "cut Renshaw and Rush's connexion, for the Journal could never succeed while they had any thing to do with it," and wrote to the same effect,) thought he would make more money of said Renshaw and Rush, than of Dr. Ryan. Drs. Graves and Stokes had not penetration enough to appreciate Mr. Swift's motives, and were imposed on. Both Drs. Graves and Stokes repeatedly wrote to Dr. Ryan, to increase this person's pay, and when he remonstrated, and said that he fulfilled his agreement with him, and could get others in his place—their answer was—"no one else shall report from the Meath Hospital;—that is to say, "you must increase his pay."

But another cause of mortal offence giv-

by Dr. R. to some of our Dublin contemporaries, was his exposing the delinquencies of the Dublin Colleges and Hospitals, the Meath Hospital included, as he did of the British institutions before the Parliamentary Committee, of which Mr. Warburton was chairman, and his refusal to defend them in this Journal. He refused to defend the gross jobbing, the purchase of professorships and physicianships, the exclusion of talent on account of religious persuasion, in the benighted and unfortunate city of Dublin*. The Portsmouth Cholera Gazette folks, after a vast deal of circumlocution and unnecessary verbiage, after the manner of lawyers, call on us to shew the MS. of Drs. Graves' and Stokes' lectures. We shall have great pleasure to shew them to any respectable member of the profession in the United Kingdom, who calls on us any morning before 12 o'clock. That's our answer†. That Dr. Stokes' lectures, as supplied us, were the worst we ever perused, is most true, but we have already observed, whether the fault was the Doctor's or the reporter's, we neither knew nor cared—we certainly did not render them into sense or English as we did his former ones—an act which our red ink corrections in the MS., and our printers, attest. But the Doctor has modestly accused us of fabricating his lectures, and is astonished how any Editor could publish such. We beg to inform him that Editors too often publish a vast deal of nonsense delivered by lecturers, more especially when they do not chuse to correct it; and farther, that Dr. Ryan is ready to leave to the judgment of the profession, his description of Auscultation, Percussion, Succussion, and Mensuration, in his edition of Dr. Hooper's Physician's Vademecum, 1838, with any that Dr. Stokes has hitherto published, or shall hereafter publish on the subjects. There is also another fact worthy of the Doctor's remembrance, namely, that none of Dr. Ryan's works has hitherto been damned, as was Dr. Stokes' on the Stethoscope, Auscultation, &c. (Vide Lancet, Medico-Chirurgical Review, Edinburgh Medical and Surgical, &c., &c.)‡

* In London no man is impeded in his profession or calling on account of his religion. In Dublin every impediment is thrown in his way, unless he professes a certain creed, though he may in reality follow which he pleases.

† Our terrified unknown, but our now known friend, who is resident in London, need not entertain any fear that we shall allow improper or interested persons to see his manuscript—To them he shall continue unknown.

‡ It is to us astonishing that Dr. Stokes could seriously suppose, the Editor of this onary journal could be so insane as to compose or fabricate his lectures delivered at the Meath Hospital, containing long histories

As to the personal scurrility of the Portsmouth Cholera Gazette people, with respect to our friend's sporting "a fine bushy, flame-coloured top-knot, &c., &c.," this is too peurile to be noticed. But we may be allowed one remark—It is most true that Nature has given our friend a luxurious capillary growth, that he is a rough-headed Irishman, as a quondam vanquished opponent once designated him, or has what physiologists consider a proof of a good supply of blood to the head, a characteristic of a sanguine temperament, of a *mens sana in corpore sano*. We thank our cholera friends for this quotation, but we are not surprised that youths who are scantily supplied with this sign of vigorous development, having a few stems of lanky growth, and who are obliged to wear scalps, for "those who have no hair, may lawfully wear a wig." should envy our worthy friend of "Dame Natures" luxuriant embellishment. These imberbous youths, the commissioners from St. Thomas's Hospital, talk of withered branches, &c.—but if they looked near home, perhaps they might discover, whether effeminacy, pusillanimity, and a premature decay of mind and body, are not their own unfortunate characteristics. In fine, we have to remark that the Portsmouth Cholera Gazette, containing attacks on Dr. Ryan, has been distributed under cover (for no one takes it) among many members of the profession; and the proprietor is so clear sighted as not to perceive, that the vituperation of our friend is the best course he could pursue to excite the hostility of the profession. Neither can he see that the tirades in his pamphlet, are (*vox et præterea nihil*.)

Mr. Williams' Letter.

The pointless remarks on Mr. Williams's letter in the Portsmouth Cholera Gazette, merely shew the excruciating agonies of the worthies he so justly castigated. That gentleman, after an experience of thirty years in public service, can bear another "contemptible piece of egotistical buffoonry"—from the commissioners!!! who intruded themselves, in his absence, into his hospital, made extracts from his private case books, published a comment on them, and afterwards made a most abject apology for libelling the government, which they accused of ordering prisoners to be kept "filthy and ill fed." We are not certain, indeed we

of cases treated by the Dr., which could not possibly be known to us. We were next accused of fabricating them from notes, &c. The manuscripts will shew, that contrary to our usual custom, we did not correct or alter a syllable in them. Our medical friends here, well know, that we are too much occupied even to compose or write out our own lectures every week, much less to sit down to "fabricate" the ideas in another man's cranium

know nothing of the fact, if fact it be, but it was announced in one of the papers of this day, that an individual very like in appearance one of the Portsmouth Commissioners, who passed the examinations at the Royal College of Surgeons and Apothecaries' Hall a few months ago has been appointed lecturer at the Westminster School of Medicine!! The cholera bulletin issued from that quarter—Now, if this were really the Portsmouth commissioner, we should ask Mr. Guthrie, who gave in evidence at the House of Commons that no man would be allowed by the College of Surgeons to lecture on anatomy, unless he had a museum that cost £1,000., &c. &c., how the appointment in the school to which he belongs, (indeed it could not have taken place with his consent and we don't think it possible that it has), could be made? The whole tenour of Mr. Guthrie's evidence went to prove that the Royal College of Surgeons were most tenacious in sanctioning lecturers; and he stated distinctly, that they should be men of standing in the profession and of known reputation. We therefore don't believe the announcement in the newspaper; but if it be true, then we shall expatiate upon Collegiate consistency—for Mr. Guthrie was the avowed organ as President of the College.

—o—
Foreign Medicine.

Remarkable Cases of Hydrocephalus.

M. ESQUIROL informed the Academie de Medecine, at the sitting of the 20th January, that when visiting the Hospital Santa Maria Nuova, in Florence, the Zanetti shewed him the head of a hydrocephalic patient, the dimensions of which were enormous: he took a copy of it in wax, and now exhibited it to the Academy.

Millimetres.

The circumference of the head is	920
The distance from one auditory foramen to the other, passing over the vertex	720
The distance from the occipital protuberance to the root of the nose, passing by the vertex .	595
The Antero-posterior diameter .	270
The transverse diameter	260

The head was thickly covered with light-coloured hair; large veins were prominent in several portions of it, and particularly about the temples. The bones of the base of the skull exist, but those of the vertex do not. The encephalic cavity is formed by the scalp and meninges alone, and contained thirty-six pounds of fluid. The mass of the cerebral lobes had disappeared, or were rather expanded in a layer over the whole inner surface of the membranes: this layer was only between one and two lines in thickness. The corpus callosum, the thalami optici, and striated bodies were visible.

The subject of this case was a little girl, who died at the age of two years and a half: she was exceedingly emaciated, and her stature, as also her intellect, was that usual to children of her age.

M. Esquirol compared the dimensions of this child's head with those of the head, also watery, of an Englishman, who died in his 27th year, and whose case was published by Spurzheim. In this instance,

Millimetres.

The circumference of the head was	880
The Antero-posterior diameter . .	298
Distance from ear to ear, over the vertex	400

The learned member also shewed the Academy the head of a hydrocephalic foetus that had been grafted to the gastro-colic epiploon. The cranium was evidently ossified: the sternum, ribs, vertebræ, and membranes were easily recognized. The woman in whom M. Esquirol found this foetus was upwards of sixty years old, had always enjoyed good health, and was lusty: her abdomen was large, but free from pain: she had resided for several years in the Saltpetriere, where she died in 1820.—*Gazette Medicale*, Jan. 24.

Foreign Body introduced into the Rectum.

M. Thiaudiere relates the following curious case in the Bulletin de Therapeutique.

A young man of twenty-two years, in order to overcome an obstinate costiveness, on the 6th of last May introduced into his rectum a wooden hook, the long branch of which was five inches long, and the smaller one, which formed the hook, three inches and a half, including the extremity or point of union of both the branches, between which the distance at their nearest junction was an inch, and two at their greatest separation; each branch was four lines thick.

This hook had been introduced with the great extremity foremost, and when the small branch had fairly entered the rectum, the youth tried in vain to extract the fecal matters with it. Sharp pains came on. He tried to withdraw it but could not; he then pushed it further up imagining that it would be dissolved like aliment. Meantime the pains became dreadful.

On the 30th May, M. Thiaudiere first saw the patient. He found it barely possible to touch beyond the end of the longest branch, and as he could form no idea of the shape of the instrument, he desired the patient to shew him one like it. After a clyster, he then made the man rest with his hands on a chair, the legs and buttocks well separated. One finger after another, he gradually introduced the whole hand into the rectum: with infinite difficulty he contrived to seize hold of the smaller branch and disengage it from the folds of the intestine: then pressing the two branches together, he at once contracted the space they and his own hand

had occupied, and thus withdrew this novel species of corkscrew entire. He calls it a footling presentation!

No untoward symptoms followed, and the patient entirely recovered in a fortnight.

Influence of Age on the Height and Weight of Man.

Numerous researches lately made at Brussels into the height and weight of men and women lead to the following consequences:—

1. From birth there is a difference in weight and height between children of the two sexes; the medium weight of boys is 3,20 kilograms; of girls 2,91; the height of boys is 0,500 metres, (the French metre is 39 $\frac{1}{4}$ inches), and that of girls 0,490 m.

2. The weight of a child diminishes somewhat up to the third day after birth, and does not begin sensibly to increase until after the first week.

3. With equal age, a man is generally heavier than a woman; it is only towards the 12th year of age that individuals of either sex are of the same weight. Between the 1st and 11th year the difference of weight is from 1 kilogram to 1 $\frac{1}{2}$ kil. Between 16 and 20 it is about 6 kil., and after this date, from 8 to 9 kilog.

4. When a male or female has arrived at its full development, they weigh nearly 20 times more than at birth, and their height is only 8 $\frac{1}{2}$ times greater than at birth.

5. In old age both man and woman lose about from 6 to 7 kilograms of their weight, and 7 centimetres of their height.

6. During the development in both sexes the squares of the weights at different ages may be considered as in proportion with the 5th powers of the heights.

7. After complete development in both sexes the weights are nearly as the squares of the heights.

From the above it may be deduced that the increase in height is greater than the transverse growth, including the breadth and depth.

8. Man attains the maximum of his weight towards his 40th year, and begins to fail in it very sensibly towards his 60th.

9. Woman does not attain the maximum of her weight until nearly her 50th year. During the breeding period, that is from the 18th to the 40th year, the weight is scarcely observed to increase at all.

10. The weight of persons measured, and who were fully developed and regularly constructed, varies within points that are about as 1 to 2; whereas weight varies only within points that are at most not more than as 1 to 1 and a third.

11. With equal heights, woman weighs somewhat less than man previous to attaining the height of 1,3 metres, which nearly correspond to the age of puberty, and she weighs a little more if the height is greater.

12. The medium weight of an individual, leaving out of consideration both sex and age, is 44,7 kilog., and taking sex into account, it is 47 kil. in man, and 42,5 kil. in woman.

Similar results were obtained by the late M. Tenon in Paris and its neighbourhood. The experiments were made on persons in easy circumstances, who for the most part exceed the lower classes in height and weight.—*Gazette des Hôpitaux*.

State of Education in Russia.

The number of professors and employes of the University of St. Petersburg is 54; that of students 206. The university district of the same city is composed of eight gymnasia or preparatory schools, and 207 other establishments, with 417 teachers and 8,781 pupils of both sexes.

The University of Moscow reckons 113 professors and other officers, and 541 students. Since July, 1833, at the suggestion of the minister Ouwaroff, the professors publish memoirs, and the students are employed in the translation of the best foreign works.

Charkoff has 52 professors and 464 students. Included in this university are 7 gymnasia and 179 other establishments, with a congress of 515 professors and teachers and 10,267 pupils.

The University of Casan reckons 209 professors, and an equal number of students. They have for some time been teaching the Mongolian language here. Particular attention is given to meteorological, magnetic, and geographical observations. In the circle of this university are 8 gymnasia and 159 inferior schools: the total number of teachers is 501, and of pupils of both sexes, 7,776.

The University of Dorpat, composed of four Faculties previous to 1833, has 67 professors and teachers, and 539 students, most of whom come from the provinces of Livonia, Esthonia, and Courland. Here there are 4 gymnasia and 270 other establishments, with 260 professors, and 8,471 pupils of both sexes.

The University of Saint Wladimir recently founded at Kiew for the governments of Kiew, Padolia, and Volhynia, reckons in its circle 7 gymnasia and 54 other schools with 168 professors and employes, and 4,609 students. Besides the six scholastic districts which are connected with the six universities of Saint Petersburg, Moscow, Charkoff Casan, Dorpat, and Kiew, the ministers report also makes mention of four others recently organized. There are 1, of White Russia the head quarters of which are at Witepak (transferred from Wilna) with 9 gymnasia, 68 other schools, 423 masters and teachers, and 8,766 students of both sexes: 2 of Odessa, composed of 5 gymnasia, and 68 other schools, with 190 professors and

3,115 students. The latest established college is that of Kischekew in Bessarabia; the best is Lycée, Richelieu of Odessa which itself includes 44 teachers and 400 pupils; 8. the College of the Caucasus placed under the superintendence of the governor of Caucasasia and Georgia. It is intended to be composed of the College of Tiflis and of 20 schools of so many cantons: 12 are already organized: 4 and lastly, the College of Siberia.

We suspect that Russian schools and scholars, like Russian armies, are much more formidable on paper than on the ground—the Colleges of Caucasasia and of Siberia!! credat Judas! *As resiste* we can well imagine the species of education received under a mild rule which permits no exit from Russia to other Universities. It is plainly not an education which

“*emollit mores nec sinit esse ferus.*”

Bleeding in Lightning-stroke.

The St. Petersburg Medical Gazette states that a soldier who had been struck by lightning was saved by copious bleeding: he was buried up to the neck in the ground, and in five minutes sensibility was restored, although the body was perfectly cold when inhumed.

Abscess of the Scalp.—Purulent Absorption.

Cyprian Blanc, aged 25, a silk weaver, was brought to the Hôtel Dieu on the 24th of March, 1838. On his forehead was a deep round lacerated wound. Above the centre of the right eye-brow there is an opening one inch in extent, in a transverse direction, and having the appearance of a wound produced by a cutting instrument. The patient says he was wounded by falling from a cabriolet. A simple dressing was made. On the 25th, M. Dupuytren carefully examined the patient; it did not appear to him that the cause stated sufficiently explained the nature of the wound of the forehead. He therefore insisted on knowing the truth, and the patient, after considerable demur and reluctance, acknowledged that he had attempted suicide with a pistol charged with a brace of small balls, which had been extracted before he came there. A probe made known a circumscribed portion of the coronal suture, bared and rough. An incision of the integuments was made. (Low diet, bleeding, pediluovia, and lint dressings.) On the 26th, after a restless night, the patient is quiet, but melancholy, and with head-ache: the upper part of the face looks erysipelatous. (Bleeding again: pediluovia.) On the 27th, the swelling of the eyelids is increased, and there is fever. The 28th; the belly is tumid and tender; the tongue red (two grains of tartar emetic; in the evening, twenty leeches to the epigastrium). The 29th: he appeared relieved by the leeches; the erysipelas is diminished.

The 1st of April: is better: erysipelas gone: sleep; appetite: some food taken. A piece of wadding was extracted from the wound; abundant suppuration. The 3rd: no general symptoms; suppuration still copious; dressing with graduated compresses. The 7th: the patient complains of having been feverish: the wound still of good aspect. The 8th: the fever and inquietude are increased: there is some delirium and tendency to stupor: the face shrunken: sub-sultus tendinum: the wound is nearly laid bare by the movements of the patient during the night: it is of a greyish colour, and nearly dry. (Twenty leeches behind the ears: mixture with two grains of tartar emetic.) The 9th: the day and night both bad; incessant delirium or coma. Sinapisms produce no effect. He is at the worst; the face is anxious, the breathing stertorous and frequent: meteorismus. Twenty-leeches again to the head, and emetic mixture. Death in the evening.

Dissection.—The skin is separated by pus for the space of half an inch around the wound: the wound is no way depressed at the point where the ball had struck, and the periosteum alone was wanting there; the neighbouring soft parts contained extravasated pus. The veins of the orbit are full of yellow purulent matter. On opening the cranium and detaching the dura mater from the posterior surface of the frontal bone, a purulent collection is found directly behind the spot where the ball had struck. Suppuration was also found between corresponding portions of the arachnoid and brain. The latter is depressed in the same place into the shape of a small cup, and is softened and greyish, while the surrounding part is red and injected. The liver is studded with yellow spots, covered with a false membrane. Several incisions pass through purulent cysts in the liver, varying in size from a pea to a nut, and amounting in number to nearly one hundred and fifty. Numerous similar collections are met with in the lungs near their surface. The abdominal viscera are sound.—*Dissert. sur la Phlébite Traumatique, by A. G. Darcy.*

Hospital Reports.

WESTMINSTER HOSPITAL.

Anthrax.

THOMAS NAAS, aged 63, was admitted this day (January 5th), into the hospital by Mr. Thompson, with severe carbuncular inflammation of the outer part of the thigh. He is a large and stout man, of plethoric habit, and evidently one who has not restricted himself to the diet-roll of Lewis Cornaro. He is a native of Dudley, in Staffordshire, where he has always resided, his employment being that of a smith in the iron-foundries. He has been in London about

two months. He states that the only material difference in his diet and mode of life since he has been in town, consists in his having taken rather freely of London porter, to which he has not been accustomed. For some time back he had noticed a trifling numbness of the outer part of the thigh, in the seat of the present disease, but this did not attract his attention, until about ten days since, when he observed two large "blisters," about the size of pigeons' eggs, in the same situation. He broke these, and the sores which were left gradually became worse, until the present period. He had applied for relief to some practitioner, who ordered him to apply poultices of linseed meal.

At the present time, the local affection consists of two deeply excavated ulcers, in the situation before indicated, with thick, everted, and highly inflamed margins, containing in their centres a dirty white slough. One of these is perfectly circular, and about the size of a five-shilling piece; the other is of a more irregular form, approaching somewhat to an oval. The two are closely approximated, and are surrounded by an extensive patch of erysipelatous inflammation, which is attended by considerable tumefaction, from subcutaneous infiltration, giving the characteristic sensation on the application of the hand. He has lost all appetite, the tongue is covered with a dirty white fur, and the bowels are torpid. The pulse is 96, full and soft. The following were prescribed:—

Rx. Hydrarg. submur., gr. vj.;
Ext. colocynth., co. gr. x M ft.
pilul. iij. statim sumend.

Rx. Haust. purgans, domest., vespere sumend.

Rx. Cataplasma. Lini constanter app.

6th. The bowels have been freely relieved; the pulse is now only 84, and not so full. The local affections remain as yesterday.

7th. The inflammation surrounding the ulcers is considerably diminished; the pulse 72; he is taking the following mixture:—

Rx. Decoct. cinchonæ, ʒ vij;
Tinct. cinchonæ, co. ʒ j;
Acid. sulph. dil. ʒ j, m. ft. mist.

Capt. cochl. ij, ter in die.

18th. He has had an attack of diarrhoea, which Mr. Thompson ascribes to the acid in the mixture; is therefore ordered to be omitted; in other respects his general health is much the same. The sloughs are separating, and the surrounding erysipelas is much decreased. The two ulcers have, however, by an extension of the ulcerative process, become united into one, upon the surface of which, a few points of pus are to be seen, which apparently makes its way from below; a considerable tumefaction remains. Mr. Thompson to-day stated in the wards, that he regarded the case as one

of pompholyx solitarius, whilst Mr. W. B. Lynn, when he saw it the other day, denominated it carbuncle. It certainly would appear to possess all the essential characters of the latter disease, in a mild form, except that the burning pain usually met with in anthrax, has not been noticed throughout; and that it commenced with larger bullæ than is general, and which might be compared to those of pompholyx.

12th. The sloughs have separated, and the ulcers are all beginning to granulate; the poultices have been omitted, and simple dressings, with the application of a roller, substituted. He continues the bark mixtures.

14th. The edges of the ulcer have lost their thickened and everted character, and the surrounding inflammation has nearly disappeared, although considerable tumefaction remains. His general health is now very good.

21st. Much better: the ulcer is rapidly healing, and the tumefaction diminishing.

27th. Discharged the hospital cured. He has returned to Dudley.

—o—

An Address delivered at the Birmingham School of Medicine and Surgery, on Monday, October 6th, 1834. By John Johnstone, M.D., Fellow of the Royal Society, and of the Royal College of Physicians.

THE following eloquent and well written address was lately delivered at the Birmingham School of Medicine to a large auditory, consisting of noblemen, gentlemen, and professional men, and excited much applause. We condense much of the lecturer's observations, as they were necessarily of local interest. We have pleasure in informing our readers, that the Birmingham School possesses an excellent library and museum of natural history; that that institution is managed by donors, who, with the eminent medical practitioners, appoint lecturers, to be removed unless they perform their duties and evince high talents. If this regulation were generally adopted in the medical schools of this empire, many noodles would be removed, and beardless, brainless lecturers allowed to "waste their sweetness on the desert air," which by the way students sometimes compel them to do at present.

"My Lords and Gentlemen - Although I have no anxiety lest the celebration of this day should prove satisfactory to you, and although I have so frequently experienced your kindness personally to myself, yet when I see so many venerable and learned persons around me—men accustomed not only to give counsel in private affairs, but even delegates to the Supreme Authority—I cannot but wish that you had assigned the part now entrusted to me to some more able hand. I am encouraged, however, to believe that my cause, if not my talents, will secure for me that benevolent attention

which, in an audience like this, whatsoever tends to the public utility is sure to meet with—and therefore confidently do I address you on the opening of this, permit me to call it, Temple of Science—not sprung, indeed, from the ashes of antiquity—not adorned by venerable recollections—not built on the remnants of columns which, in their pristine glory, supported an edifice dedicated to science, and worthy of its author; but an establishment altogether new, altogether the work of our own compatriots, created by their own hands, furnished by their own industry, and to be perpetuated, I trust, by the continued munificence of you, its noble patrons—and of you, its learned, its industrious, its vigilant, and its exemplary instructors and promoters.

“Well knew our ancestors that, where instruction was to be imparted, *there* instruction should have a home and an abode: they well knew that the seed cast on the sand had little chance of rooting. From the earliest beginnings of this institution, it was a necessary part of the meditation of the founders to have regard to a domicilium—to a place of refuge, as it were, where those who taught might resort, and where those who wish to learn might attend. In the beginning of our institution, narrow indeed were the means, few were the powers, and small the accommodations of those persons whose intentions have been thus far realized this day. Though Birmingham may be called the metropolis of the west, it has hitherto brought forth no Linacres to frame a royal foundation of science, no Harvey to enrich it with invention and to illustrate that philosophy which Verulam has now made universal and immortal. Yet may we gratulate ourselves on making no humble attempt. Yet do we hope that the foundations of our academy will be laid deep and firm; and with the patronage of such friends as those who now surround me, and of such moreover as decorate our list, surely we have a right, not only not to despair, but even greatly to hope.

“In tracing the history of this school, the work is in so narrow a compass that I need not detain you long in the detail. From small beginnings under our own eye has the Medical and Chirurgical School advanced to its present height. We have witnessed its birth, we have watched its growth, all about it is clear and ascertained, and some among you have the greater reason to be proud, because, in contemplating it, you contemplate the work of your own hands and your own minds. To Mr. Sands Cox is due, not only the formation of the school, but the idea in which it originated. After a liberal education in his own country, he visited Paris in 1824 for the express purpose of preparing himself for delivering lectures in anatomy and surgery. In October, 1825, he first submitted his plans to the Profession

in Birmingham, and delivered his inaugural lecture. In 1826 and 1827, for the purpose of obtaining information, he visited the schools of Edinburgh, Glasgow, and Dublin, still continued to recommend the formation of a regular school in Birmingham; and, by that impulse which zeal and talent are sure to impart, in 1828 he gained the patronage of some of the seniors of the Profession in Birmingham, and the school was constituted.

“That there might be neither monopoly, nor the appearance of monopoly or exclusion, the lectureships were offered to all the physicians and surgeons, hospital and dispensary; according to seniority; and Dr. Pearson, Dr. Booth, Dr. Eccles, Mr. Jukes, and Mr. Ingleby undertook the task of lecturers in the several branches of medical science; and although Dr. Booth and Mr. Jukes did not long retain their posts, yet was the school materially served by their zeal and activity, whilst they continued lecturers. The school was then formally opened by an eloquent address from Dr. Pearson. Pupils flocked to the lectures, and all the Physicians of the General Hospital threw open their practice to them without fee; and thus a regular train of instruction was laid. Long before this period, clinical discourses had been delivered at the General Hospital, and in the end the example originally set there was followed by the dispensary. The physicians to the latter institution liberally opened their practice to the classes; and thus the clinical part of the instruction became general after 1832.

“Up to 1829, the School had only the convenience of one room for all its purposes. In consequence of this narrowness of accommodation, the Lecturer in Anatomy offered to build a set of rooms, provided the body of lecturers would guarantee a certain rental, for the reception of the Museum and Library; and in order to learn how to arrange the Anatomical Museum in the best form, our enterprising and unwearied founder undertook to visit various collections in France, Germany, and Italy. On his return, the means of founding a Museum and Library appeared so scanty, that it was determined, in 1830, to solicit the aid of the neighbouring patrons of science to extend the plans and the usefulness of the Institution. The aid was liberally granted, and the donations of our benefactors, to the amount of £900., were expended in the purchase of preparations, expensive books of plates, and the fitting up of the Museum and the Library. The institution now assumed its present form and feature, and the different offices were filled up as they at present stand. In 1832, a catalogue of the Museum and Library was published; prizes of ten guineas were offered by Edward Johnstone, M. D., and of five guineas each by T. Lane Parker, and Edward T. Cox, Esqs., given to Mr. James Wilkes and Mr. Hammond, for their compositions; the first, on the Sympathetic

Nerve, was adjudged by Dr. Peasman, Dr. Eekes, and Mr. W. S. Cox, and the other, on Hernia, was adjudged by Sir Astley Cooper. Sir Kardley Wilmet next gave a gold medal, and E. T. Cox, Esq., who has been one of our most zealous benefactors from the beginning, another, for the best anatomical preparations; and finally, a gold medal is offered by John Meredith Esq., for the best Essay on the Blood. To these honorary stimuli the pupils have ably responded; the treatise of Mr. James Wilkes and Mr. Hammond, which have been printed and given to the public, deserve, and would have received commendation from either of our Universities; and the preparations of Mr. John Elkington could not fail to extort praise even exhibited to the experienced eyes of London and Paris Anatomists.

"I have particularized the names of these students, because they have received the public honors of the institution. There are many other preparations, from other hands, highly distinguished by their merit, and there are other works read amongst themselves which evince the ardour, the diligence, the originality, and the intelligence of the aspirants; but these exertions and these merits have been praised in better terms than I can express them in, by the celebrated men who have probed the qualifications of the students annually, at the set examinations. I wish the time would allow me to repeat them all, but we can none of

us forget the emphatic commendation of Mr. Beansby Cooper, whose lecture on Hernia we listened to with so much admiration, at the first public meeting, in this very room. The fruits of the Instruction received in the School have indeed manifested themselves so conspicuously, that it is our pride to be able to point out gentlemen educated here who have been marked with praise and distinction, not only by the public examiners in London, but at this hour we can boast of practitioners, settled in several counties around us, who are diffusing the benefits of their good education, and are already receiving their due honours and rewards from the public confidence."

CORRESPONDENTS.

Mr. Williams—The word Portsmouth was substituted for Plymouth, as the latter had not been previously mentioned in the letter, and was supposed to have occurred in the haste of writing.

Castigator—Will find his communication in this number.

Medicus—Billingsgate is not libellous—the article is under consideration.

Hibernus—We daily expect the lectures.

LECTURES

ON

MEDICAL JURISPRUDENCE,

DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,

At the University of London; Session 1834-35.

LECTURE XVII.

Assurance of Life.

GENTLEMEN—The next subject that demands our attention is Assurance of Life

It is a universally admitted axiom, that nothing is more uncertain than the duration of life, when individuals are referred to; for when we examine the mortality of communities, it is truly curious to remark the uniformity of annual mortality, the excess of deaths in any year rarely averaging more than a small fractional part of any given number of years. It is upon this principle that life Assurance Companies have been formed; and it is easy to comprehend the mutual advantage which must result both to the assurer and the assured: in the one case the advantage arises from the little change in the average of annual mortality in a society or large body of individuals; in the other case, the advantage arises from the uncertainty of human life, as far as concerns individuals.

It is not necessary, in a Course of the nature of this one, to demonstrate the basis of the calculations which have been made to insure a profit to the assurers: I may only remark that it proceeds upon the knowledge of the average mortality of any given number of persons, at different periods of life, and the period which is required for the death of the whole. It is with individuals that we have to do; and therefore, in order to form our opinion of risks, and to state it in certificates of health, and in courts of civil law, we must make ourselves acquainted with the probabilities of death, at different periods of life, as this has been determined by long and accurate observations. We must also take into account the effects of several trades and species of labour in regard to the health of the individuals exercising them;

VOL. VII.

the rank of society in which the individual who is about to insure his life is placed; for it is evident that persons in the middle and higher ranks of life are exempt from many sources of unhealthiness to which the labouring classes are liable. At the same time, much depends on the habits of the individual, to whichever class he may belong; whether these are sedentary or active, whether he is temperate or luxurious, and whether his mind be highly cultivated and exercised, or be allowed merely to vegetate. The advice of the late Dr. James Gregory, to a hypochondriac patient in high life—"Live upon sixpence a day, sir; and work for it"—is of more general application than is commonly supposed.

In looking, also, at the probability of health and of life, we must take into account the residence of the individual: thus, in reference to England, we find that, according to computations which can be depended upon, the average of deaths in 1780,

In Middlesex, were 1 in 36—	1821, 1 in 47.
Kent	1—41
Warwickshire	1—42
Cambridgeshire	1—44
Essex	1—44
Surrey	1—45
E. part of York- shire	1—47
Lancashire	1—48
Sussex	1821, 1 in 72.

The average of the annual deaths in England, in 1780, were 1 in 40; in 1821, 1 in 58; in Scotland, in 1801, the average mortality was 1 in 56.

Stepping out of our own country, and looking at other countries, we find that the average is generally greater than the mean of those which I have just mentioned; but we also find that this depends rather upon the habits of the people, the degree of advancement to which medical science has attained, and the variable supplies of provisions, than on local causes connected with the country and its topography. Thus, in Sweden, a country subject to frequent scarcity of provisions, and where medical education and skill are proverbially bad, we find the deaths annually averaging 1 in 35; in th

Pays de Vaud, 1 in 48; in Russia, about 1 in 41; in France, 1 in 40; in Prussia, 1 in 35; in Naples, 1 in 35; in Wirtemberg, 1 in 33; in the United States, 1 in 40; whereas, in this country, in an equal period, say fifteen years, the average does not amount to 2 per cent., or 1 in 50.

Such are the principles upon which Life Assurance Offices are founded, and upon which the calculation of their profits are grounded, so as to give a fair anticipation of success: but this, after the best calculations, can only be secured by guarding against every circumstance that can tend to render these fallacious, by interfering with the ordinary risk of life. Every Insurance Company, therefore, requires that the party on whose life an assurance is to be made should appear personally at a meeting of the Directors, or, if he do not appear, a higher premium is required, because the probability is that some latent disease may exist in this individual, which, although it be not observable to others, yet may be detected in the countenance of the person, by the experienced eye of a medical practitioner. This source of security to Assurance Offices, therefore, is obtained, either by a sum of money adequate to the risk, or by the examination of the proposed candidate for assurance by a medical practitioner; thence the necessity for making this a subject of instruction in a Course of Medical Jurisprudence.

It is of great importance to every Assurance Company to have medical practitioners attached to it, on whose honour and integrity they can depend, not less than upon their medical skill; for, if the mind of the examining physician do not rise superior to temptation, it would frequently happen that he might be induced to overlook the circumstances which constitute a bad life: thence the necessity for moral rectitude, to maintain not only individual character, but also the honour of the profession. Skill, also, is required, and the exercise of a nice discrimination in the investigation of the previous and general state of health of the person applying to be insured. But, besides having medical practitioners attached to the offices, Assurance Companies require a declaration from the usual medical attendant of the person about to insure, that he is not subject to any disease tending to shorten life; and also, that the party is not addicted to any habits that are likely to abbreviate the ordinary term of life. There is no compulsion on a medical man to reply to such a demand from an Assurance Office; but the Office rests secure that their communication will be answered, as it equally obliges the person to be assured and the Office; and a practitioner refusing to reply to it would certainly stand a good chance of losing a patient. This certificate is supposed to be correct, and the circumstances mentioned in it to be reported on his personal knowledge of the party. Instances have occurred of

false certificates having been obtained; but the exposure of some of these has proved that such conduct is not safe, whilst these cases have also brought into Court others in which unjust suspicion has been thrown upon the medical men who have granted certificates, and examinations have taken place, which have placed medical witnesses in a very awkward and uncomfortable situation; it is, therefore, necessary that the practitioner should be prepared to meet every question which may be put to him in the course of a cross-examination. Thus, a medical man certifies that the person about to be insured enjoys *good health*: but he has not perhaps attended that individual for a considerable time; or perhaps, although he may have attended the family of the person who applies for the certificate, yet he may never have prescribed for him. In this case, he must be certain that he has enjoyed good health, and has not been the patient of another during the period alluded to. There is also a case in point, published in Mr. Amos's printed Lectures, in which that gentleman was counsel. (See Med. Gazette, vol. viii, p. 197.)

I recollect, also, in a case of this kind, that the counsel put this question—"Pray, sir, what do you mean by health?" The reply was a natural one—"The absence of disease:"—but this was not satisfactory, and brought forward another question—"What is disease?"—which I recollect was very indifferently answered; and, consequently, did not raise either the character of the practitioner or that of the profession in the opinion of the Court. Now, let us consider what the answers ought to have been.

Health may be defined the due performance of all the functions of the body and the mind. *Disease* is that state of the body in which one or more of its functions are irregularly or imperfectly performed. But another question arises—How are these states to be judged of? With regard to the first state, that of health, our opinion may be formed, with some degree of accuracy, from an attentive examination of the countenance, of the attitude, of the general state of the surface of the body, and of circumstances connected with the functions of the brain, those of the chest, and those of the abdomen. With regard to the second state, that of *Disease*, besides involving the negative of the healthy phenomena, it also comprehends the whole doctrines of diagnosis.

1. With respect to the appearance of the countenance in health, this must vary with age: but as you are not likely to be called upon to answer questions relative to the insurance of infants, nor those far advanced in years, I shall confine my remarks to youth and adult age. In youth, whatever may be the form of the head or contour of the countenance, health is indicated by a firm, elastic state of the cellular membrane, and a vivid complexion, perfectly distinct from tumidity

or bloatedness, and still more obviously the reverse of that shrinking of features, which is the result of disease. The muscles are not marked by abrupt elevations and depressions, but are filled up, so as to afford roundness, which, with the injected state of the cellular membrane, affording both elasticity and colour, are the chief characteristics of health, as far as it is indicated by the countenance in youth. In the female, some circumstances vary these appearances, although they cannot be regarded as indicating disease. Thus, just before and during the menstrual discharge, the complexion becomes less clear and fair, some degree of blackness appears around and below the eyes, the tongue is loaded, and the breath slightly tainted. In the early months of pregnancy there is a peculiar relaxation and enlargement of the features, and the countenance is somewhat tumified; and in the latter stages there is, usually, an expression of uneasiness. It is of great importance not to confound these appearances with those of disease. In adult age, the circulation being more moderate in force than in youth, the cellular membrane is less firm and elastic, and depressions at the insertions of the muscles, or wrinkles across their fibres, do not indicate disease. At this age the subcutaneous veins are very obvious, but this must not be confounded with their varicose state. In health, in the adult, we may expect to find strength, without great activity; nevertheless, each function should be performed with ease, and without turbulence; and from the state of the circulation, the complexion is usually less florid than in youth; besides, the influence of disease over the countenance and complexion is less obvious. If the teeth have fallen from their sockets, and the alveolar processes are absorbed; if the lower jaw is more elevated; if the lips are drawn inwards over the gums, and the mouth appears to be lessened in depth; if the muscles are deeply marked, the skin sallow, and the veins communicate a dark hue to the face, or it is pallid and exsanguineous; these are characteristic either of premature old age, or of disease.

In judging, however, by the countenance, we must take into account the temperament of the individual, his state of mind, and several other extraneous circumstances, which modify the character of the face even in health. In those of a sanguine temperament, the complexion is more than generally florid in youth; it is of a deep hue in adult age; and the expression is soft. In the bilious temperament it is dark, the cellular texture compact and somewhat rigid; the eyebrows large and dark, the beard strong, and the iris and hair dark coloured. In the phlegmatic temperament, the countenance appears usually slightly tumified, the elasticity is defective, and the countenance is pale and sallow; the hair is apt to be lightly coloured, and the eyebrows

and beard are scanty. As far as regards the mental expression of the countenance, the causes which produce anger, fear, grief, anxiety, or despondency, are incompatible with health, whilst those of contentment, gaiety, and openness of countenance, indicate both a happy state of mind and a healthy condition of body. But several extraneous circumstances greatly modify every indication to be deduced from the countenance, and ought, therefore, to be kept in view: these are chiefly bodily exercise; the temperature of the weather or the room in which the examination takes place; repletion of the stomach, the free use of wine; or a state of defective nourishment.

The negative of these states indicate disease; but we must, in this case also, remark the state of action of the muscles, whether any unusual or inordinate actions exist, either general or partial, and whether these be really the effects of disease, or merely of a bad habit: as irregular and spasmodic movements of the muscles of the face may exist, and yet the patient be in the best possible health. It is unnecessary to enter upon the details of the effects of different diseases on the countenance; each has its peculiar characteristics, with which every man who pretends to cure diseases should be familiar.

With respect to *attitude* indicating health, the body is usually supported on one limb, whilst the other only moderately aids the maintenance of the body from falling, and is generally placed at a short distance, laterally, with the toe turned out; the trunk is gently inclined to the opposite side; the head is placed upright; and in the lateral aspect the spine appears gently curved. If the body be in motion, we find that in youth the step is rapid, quick, and elastic: in adult age, the step is firm and the body erect, but the gait is less elastic and more steady. If all elasticity be lost; if the step be slow and insecure; and the spine be much curved forwards, at this period, there is much reason for suspecting the presence of disease. In pregnancy, the natural attitude of the healthy female is altered, and in both sexes it is influenced by the state of the mind, and several extraneous circumstances, all of which ought to be taken into account in forming our estimate of health from attitude. In some diseases the criterion of attitude is much to be depended upon; thus, the erect posture is an uneasy one in vertigo; it is unnecessary to say how obviously paralysis is displayed by attitude and movement; in phthisis some particular posture is chosen in which the cough and dyspnoea are less oppressive than in any other, and in asthma there is an elevation of the shoulders, and an inclination backwards of the head, to fix the scapular and other muscles which aid the elevation of the chest during the paroxysm, and habit maintains this position when it is absent. In incipient affections of

the heart, on suddenly rising up, or on any rapid movement, a degree of dyspnoea is immediately induced: and in the same manner many other diseases are characterized by attitude or posture.

It is unnecessary to proceed more into detail in this part of our subject; the diagnostic appearances of diseases cannot be too closely studied for the advantages to be derived from it in practice, independent of its importance in determining on the propriety of insurances; and in this case, it is of more importance to ascertain the presence of health, than to determine the existence of any particular disease; neither is it necessary that a state of the most perfect health exist, in order that a medical man may, conscientiously, give a warranty that a person is in *good health*: it is sufficient that the individual enjoy a reasonable state of good health. The extent to which this may be carried is well exemplified in an action on a policy made on the life of Sir James Ross, quoted in Paris and Fonblanque's work, from Park on Insurance, which I will read to you*.

I have quoted this case to shew you to what extent a practitioner may legally venture in giving a warranty of health; but, at the same time, I would not advise you to act upon it; no physician, in my opinion, could lay his hand upon his heart and affirm, that with such an infirmity as Sir James laboured under, his life was a good one; and although the partial paralysis which afflicted him had no immediate connection with the malignant fever of which he died, yet by diminishing the powers of vitality it undoubtedly rendered him more susceptible of diseased impressions, and less likely to shake them off when they had fixed upon the habit.

In the printed queries issued by the Assurance Offices, several diseases are expressly named as tending to shorten life. Now the question is, What is the meaning of the term disorder to shorten life? It has been ruled that in this term is not to be included any disorder which is neither organic nor excessive, with which a person is afflicted before he effects an insurance on his life†.

From the tendency of the legal opinion in this case, it is obvious, that the warranty of a medical man, that a person has no disease which tends to shorten life, does not imply that he possesses that state of health which may be strictly termed perfect. The warranty in these terms only implies that he enjoys a state of health which may reasonably be regarded as good, in the common acceptance of the phrase. The question, Has he or she had the small pox? is always put down: for, when this has not occurred, and the person has not been vaccinated, the risk is justly thought to be augmented, and the

premium is considerably increased. I have said, *justly* thought to be augmented, because it has been demonstrated, by the clearest evidence from the most extensive inquiries, that the introduction of inoculation and vaccination has increased the mean duration of human life about three years and a half; and on this evidence a Monsieur Duvillard has computed tables, from which the risk arising from the chance that a person who has not been inoculated or vaccinated shall die of the small-pox, may be known, for any age. It is, nevertheless, a curious fact, that at one of the best Assurance offices, the Equitable, although a person who has been vaccinated is admitted on the usual terms, yet, if he die of small-pox, his policy becomes void. This is a regulation of the society, with which every person who insures in it is made acquainted, otherwise its equity might be justly questioned.

Another disease particularly specified is gout: Has he or she ever had gout? the probability of the recurrence of the disease being calculated upon, and a higher premium, consequently, is demanded. The hereditary nature of this disease, however, does not legally affect a warranty of health, as was decided by Lord Mansfield in a case, *Willis versus Poole*, which was a case of gout. "Such a warranty," says the learned judge, "can never mean that a man has not the seeds of disorder. We are all born with the seeds of mortality in us. A man subject to the gout is a life capable of being insured, if he have no sickness at the time, to make it an unequal contract." It is a curious fact, that out of 152,000 persons, insured in the Equitable Insurance office, from the year 1800 to 1821, of every age, from ten upwards, only twenty-six died of gout: the supposition, therefore, that gout tends to shorten life, is at least problematical. In filling up an insurance paper, however, the fact of the individual having had attacks of gout ought always to be mentioned; although the fact just mentioned would justify us in regarding it a disease not likely to shorten life. In filling up a certificate of health, if no specific question be put concerning gout, you are not bound to take any notice of it, in reply to the general question, Has he or she any disorders which have more or less a tendency to shorten life? As this, however, is a question involved in every medical certificate required by Insurance offices, before they issue a policy, and, as medical men are liable to be called upon to justify their certificates in open court, it is requisite that you should be well prepared to reply to the interrogatory, What are the diseases tending to shorten or endanger life? In strictness, every disease, however trifling, has a tendency to shorten life; but this is not the meaning of the parties: the question refers to those only which have a very decided influence in shortening life; such, for

* See vol. 1, p. 383, or 2 Park, 649.

† See Taunton's Reports 4, p. 763.

example, as apoplexy, ascites proceeding from some organic derangement of one or more of the abdominal viscera, cancer, hæmoptisis, pulmonary consumption, angina pectoris, lumbar abscess, and frequent vertiginous attacks. If any of these, or such like, exist in the system of the person to be insured, they ought undoubtedly to be noticed, otherwise the contract between the insurer and the insured is not equal. Insanity is another disease which ought to be noticed, not because it directly tends to shorten life, but because it is often complicated with epilepsy, apoplexy, and other diseases which have such a tendency. Fits of any kind are also grounds of exception, which are generally specified in the printed certificates; but, when this is not done, it is the duty of the medical practitioner particularly to mention them.

In almost all the printed queries of the Insurance Offices, a quest on is put respecting the tendency of the patient to attacks of stone or gravel. In forming your opinion upon this subject, you must not only take into account the condition of the person at the time, but the constitutional predisposition in the family, to such diseases; for this is peculiarly marked in some families, and has proceeded for successive generations. It is not necessary, however, to mention this in your answers to the Insurance Office; but the knowledge of the fact should make you more particular in your inquiries than, under other circumstances, you would think requisite. And these remarks, in a still more striking manner, relate to phthisis.

But the most difficult query to reply to is that which relates to any circumstance which, in the opinion of the medical man applied to, would render the assurance of the life hazardous. In this sweeping query many things are comprehended. Thus, a person may be free from either organic or functional disease, yet his mind may be so harassed by anxiety, from many causes, as to tend greatly to shorten the term of his life. I know of nothing more strikingly illustrative of this fact than the cause and fatal issue of the disease termed nostalgia by systematic writers on medicine. In this disease the causes are solely mental—a strong desire in a person who is in a foreign country to return home, without the possibility of accomplishing his wish. In the first instance, the spirits sink, the person becomes languid, pensive, emitting deep sighs, and losing interest in every thing around him. The liver and stomach soon feel the diminished energy of the nervous system, dyspepsia supervenes, the secretion of bile becomes unhealthy, tremors of the limbs succeed; and, as the whole of the secreting organs suffer, the lungs, especially if latent tubercles exist there, soon share in the general morbid state of the habit, and phthisis gradually displays itself. Dr. Avenbrucker, who has written on this disease, observed

that in several who died of it, the lungs were adherent to the diaphragm, in some parts indurated, and in others purulent. Here is an evident proof how powerfully mental causes operate, and, consequently, how essential it is not to overlook them in replying to the query to which I have referred. The very circumstance of a consciousness that some mental anxiety pressing on the powers of the constitution was likely to terminate in bodily disease, may indeed be the origin of a desire to effect the insurance; and, if this be known to the medical attendant, not to communicate it would invalidate the policy.

With respect to intemperance in reference to the abuse of spirituous liquors, there can be only one opinion of its influence in sapping the powers of life; every repetition of debauch deducts something from the strength and vigour of the constitution. To employ the elegant language of Dr. John Reid, "some leaves fall from the tree every time that its trunk is shaken:" and the dreary nakedness of winter is brought on long before that season would have commenced in the regular course of nature. But there is one species of intemperance, which is neither so easily detected nor so readily pronounced upon; I refer to the abuse of opium, the habit of indulging in the use of which is daily gaining ground in this country, to a most alarming extent. In an interesting Essay on the effects of opium eating, on health and longevity, published by Dr. Christison, in the 110th number of the Edinburgh Medical and Surgical Journal, and copied into the Medical Gazette of the 14th of January, 1832, we find that the opinion of that distinguished medical jurist is, that the habitual use of such a narcotic as opium, by disordering the digestive functions, and producing obvious emaciation and premature old age, cannot be consistent with the enjoyment of health in general, and is very greatly against the chance of an average prolongation of the term of human life; consequently, that the "*life of the opium eater is uninsurable.*" My own experience fully justifies this opinion of Dr. Christison: I have known several opium eaters, but all of them died of worn out and emaciated constitutions. Death from duelling, suicide, and all violent means that might have been avoided, nullifies a policy of insurance*.

Such are the chief circumstances to be attended to in framing your report respecting the insurable or noninsurable nature of a life. Under every circumstance, you must bear in memory that you have two duties to perform—one as a member of society, called upon to do justice between man and man, the other as a member of an honourable profession—and that neither of these characters can be upheld except by an implicit adherence to truth.

LECTURES ON THE INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF
MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE X.

IV.—The fourth of the formerly proposed distinguishing features in the structure of organized beings, furnishes the foundation for what is called **ORGANIC CHEMISTRY**, or that science which professes to describe the proximate principles of the tissues and fluids of plants and animals.

Inorganic matters may be either elementary or compound, and the latter may contain indiscriminately any of the fifty-four ponderable elements of all things: any single compound, however, has often only two such elements, and the combination, even when it has three or four, is always indirectly binary, being first one with one, and the compound thus formed, afterwards uniting with either an element or another binary substance. An organized being, on the contrary, is always an aggregation of compounds, each of which, while it can contain only certain definite elements—the chief of which are oxygen, hydrogen, carbon, and nitrogen, to which are sometimes added, in much smaller quantities, iodine, fluorine, chlorine, phosphorus, sulphur, aluminum, calcium, potassium, sodium, and some others, in all nineteen—has very rarely fewer than three or four, which are, at least after the cessation of its vitality, combined together directly into a ternary or quaternary substance. Again, an inorganic compound, the chemical nature of which has been once ascertained, may be in general easily imitated artificially; since its elements are associated, as well as held together, by common chemical affinity. An organic compound, on the other hand, however easily—at least after the cessation of its vitality—it may be analysed, cannot, if ternary or quaternary, be formed by art; since its elements, although after their association, held together by common chemical affinity, are always associated by a process called secretion. (*a*) Lastly, in an organic compound, the combination of the elements is too energetic to admit of any tendency to spontaneous separation; whereas, in an inorganic compound, such is commonly—after the cessation of its vitality—the weakness of this combination, if it be ternary or quaternary, that it generally tends rapidly, under favourable circumstances, to decomposition.

By the term proximate principle, then, is to be understood a vegetable or animal compound, formed directly by the union of certain elements, and characterized by distinct chemical properties, and, by its union again with others, contributing to form the several tissues and fluids of organized beings (*b*).

(*a*) It is true, some few vegetable and animal compounds—ternary, as stearin, or at least a fatty substance resembling it, and even quaternary, as urea, or at least something like it—are said to have been formed artificially, the former by Bérard, and the latter by Wöehler; but the accounts are rather apocryphal—at any rate, so rare at best have been such manufactures, that they cannot invalidate the general proposition advanced above. We know, indeed, that binary compounds, such as carbonic acid and water, may result equally well from common chemical affinity as from secretion; and there is nothing, therefore, irrational in the idea that ternary and quaternary compounds might do so likewise; but such combinations are certainly not commonly nor easily effected in a chemical laboratory. It has, nevertheless, been considered not improbable that we shall, in future, be able to form artificially, not only organic proximate principles, such as albumen, gelatin, and fibrin, but proper tissues

also, and even whole organs, such as bones and muscles; (*Edinb. Review*, vol. XXIII, p. 389); so that it may be hoped it will not much longer remain a secret.

What medicine 'twas that Paracelsus
Could make a man with, as he tells us;
and that we shall shortly be able to imitate the philosopher mentioned by Amatus Lusitanus, and compound a child outright, “marrow, bones, and all,” by the help of a pestle and mortar!

(*b*) Organic chemistry is a science of comparatively recent date. The ancients made nothing intermediate between their *στοιχεῖα* or elements, on the one hand, and their *διμοιομενῆ*, or simple organs, and *τύπα* or fluids on the other; and the earlier modern chemists are either quite silent on the subject of proximate principles, or speak often with the utmost indecision and vagueness. The two Rouelles and Scheele made some slight advances in the science about sixty years ago; but it is hardly thirty years

The proximate principles of vegetables contain in general a great proportion of carbon, while they are commonly destitute of nitrogen, and they are for the most part ternary (a); whereas those of animals contain usually much nitrogen, while they are in general comparatively deficient in carbon, and they are for the most part quaternary. The former, again, among the less common principles, contain more frequently potassium, whereas the latter contain more frequently phosphorus, sulphur, calcium, and sodium; and, while it is in vegetable compounds only that aluminum has hitherto been detected, animal compounds alone have afforded fluorine. Of course, from their deficiency of nitrogen, vegetable compounds in general are less prone than animal to that modification of spontaneous decomposition called putrefaction.

The following are the chief proximate principles—as composed at least of the four chief elements above alluded to:—

OF PLANTS.

I. *Binary.*

(Of oxygen and hydrogen).

Water.

(Of oxygen and carbon).

Oxalic acid.

(Of carbon and hydrogen).

Coutchouc.

II. *Ternary.*

(Of oxygen, hydrogen, and carbon, the two former in the same proportions as in water).

Sugar

Tannin

Sarcocoll

Fecula

Glycyrrhizin

Inulin

Olivile

Hordein

Piperin

Lignin

Gum

(Of the same principles, but with the oxygen in excess, with respect to the hydrogen).

Acetic

Sinapic

Strychnic

Citric

Kinic

Morox, lic

Tartaric

Gallic

Benzoic

Ellagic

Malic

Pectic

Meconic

Fungic

Boletic

Acids.

Acids.

(Of the same principles, but with the hydrogen in excess, with respect to the oxygen).

Resin

Camphor

Stearin

Cerin

Elain

Myricin.

(Of hydrogen, carbon, and nitrogen).

Hydrocyanic acid.

OF ANIMALS.

I. *Binary.*

(Of oxygen and hydrogen).

Water.

II. *Ternary.*

(Of oxygen, hydrogen, and carbon, the two former in the same proportions as in water).

Sugar.

(Of the same principles, but with the oxygen in excess, with respect to the hydrogen).

Acetic

Formic

Acids.

(Of the same principles, but with the hydrogen in excess, with respect to the oxygen).

Resin

Cetin

Stearin

Ambrein

Elain

Butyrin.

Cholesterin

since Dr. Rostock drew, for the first time, any thing like an accurate distinction between some of the leading proximate principles of organized beings, (*Nicholson's Journal*, 1805), and it is since that time that the subject has been taken up by Gay Lussac and Thenard, Berzelius, Marcet, Brande, Prout, Chevreul, Gmelin, John, and so many other savans, that perhaps no branch of science at present offers, as M. Virey observes, a more "brillante carrière de nouveautés." It is true that many of these "nouveautés" are but the naked results of analyses undertaken apparently without any motive, and of which one at present sees neither the immediate advantage, nor the ul-

timate scope; but, perhaps, when some powerful and comprehensive mind shall have arisen to do for organic chemistry what Bichtat did for general anatomy, and Haller for physiology, we may be able more fully to appreciate the value of many facts, of which it seems at present that, in the words of Seneca, "Hic usus inventorum fructus est, invenisse."

(a) It is from the fungous and cruciferous orders of plants that some of the vegetable compounds which contain nitrogen are obtained in the greatest abundance; but there are few orders which do not afford, in greater or less quantity, compounds containing this principle.

III. Quaternary.

(Of oxygen, hydrogen, carbon, and nitrogen).

Osmazom	Solania
Sodo-albumen (a)	Atropia
Colouring matter	Hyoscyamia
Extractive	Daturia
Cathartin	Strychnia
Colocyntin	Emetia
Asparagin	Cinchonia
Gliadin	Quinia
Narcotin	Brucia
Zymom	Morphia
Fungin	Delphia
	Picrotoxia
	Veratria.

III. Quaternary.

(Of oxygen, hydrogen, carbon, and nitrogen).

Osmazom	Fibrin
Sodo-albumen	Casein
Colouring matter	Salivary matter
Piciomel	Hematosin
Urea	Lithic
Gelatin	Allantoic
Mucus	Cantharidia (b).

} Acids.

Of the foregoing proximate principles, but very few comparatively are described as entering into the composition of the tissues of either plants or animals, the greater number being found in the fluids alone. Among the former, however, are lignin, osmazom, sodo-albumen, and fungin, which are said to constitute, with much water, and a small proportion of certain salts, the principal tissues of plants; and osmazom, sodo-albumen, gelatin, and fibrin, of which, with a still greater quantity of water, and a similar proportion of certain salts, the chief tissues of animals are represented as consisting. Thus, it is of sodo-albumen and gelatin principally, that the cellular tissue, as well as the several membranous tissues, and the vascular tissue, in all its modifications, is described as consisting, as it is of osmazom and sodo-albumen, chiefly that the nervous tissue, and of osmazom, sodo-albumen, gelatin, and fibrin, for the most part that the muscular tissue are said respectively to be composed.

The following are some of the characteristic chemical properties:—

OF OSMAZOM.	OF SODO-ALBUMEN.	OF GELATIN.	OF FIBRIN.
Sol. in both water and alcohol, cold and hot.	Sol. in cold water.	Sol. in hot water.	Insol. in either water or alcohol, cold or hot.
Coag. by tannin.	Coag. by alcohol.	Insol. in alcohol.	Coag. spontaneously.
	— by heat.	Coag. by cold.	
	— by tannin.	— by tannin.	
	— by salts of tin, lead, mercury, & silver.	— by salts of tin and silver.	

Now the question arises, What claim have the animal compounds just enumerated—to say nothing, for the present, of those of vegetables—to be regarded as really organic elements, or the proximate principles of the organized animal body? The substance of such a body has been elsewhere represented as consisting of certain tissues, organized or unorganized, or anatomical elements, and of certain fluids; and it is commonly believed that such tissues and fluids are all immediately composed of more or fewer of these animal compounds, the simple or primary elements of which have been associated by secretion. It has, however, been already stated incidentally that, however true this doctrine may be with respect to the unorganized tissues and fluids, it is more than doubtful with respect to the organized tissues, the chemical nature of which appears to be entirely *sui generis*, but, nevertheless, such as, immediately upon the cessation of their vitality, to resolve them into some of the compounds under consideration. The organized tissues have never—as was at

(a) It has been considered expedient to designate by this name albumen in its uncoagulated state, since it is to the possession of its soda, as shown by Dr. T. Thomson, that it owes all the properties by which it is recognized. The term albumen strictly means coagulated albumen, since it is only upon the principle of abstracting its soda that all the agents by which the coagulation of this substance is effected, operate.

(b) In the above table those compounds

only are mentioned which result directly from the process of secretion, and are found native in the several tissues and fluids of organized beings; since with those into which they may be subsequently converted by various chemical manipulations, we have at present nothing whatever to do. The leading principles of the arrangement followed above are those suggested by MM. Gay Lussac and Thenard.

the same time remarked—manifested, while still possessed of their vitality, that globular structure which appears to be proper to sodo-albumen, gelatin, fibrin, and so forth; and it has been noticed from a very early period as characteristic of such tissues, that they resist, so long as their vitality lasts, the action of all those ordinary chemical agents which operate with the greatest energy on their reputed proximate principles. Does water, either cold or hot, act in dissolving, or alcohol in coagulating, an organized membrane, which is nevertheless said to consist principally of albumen and gelatin; or does either water or alcohol display any solvent action on an organized nerve or muscle, which is still represented as containing osmazome(a)? It is a distinguishing property of fibrin to undergo spontaneous coagulation; but no such coagulation takes place in muscles—which are still described as containing this principle—till they are deprived of their vitality, when they rapidly become stiff; and it is to this cause, and not to the contraction of the muscles, that the rigidity of the limbs, which soon succeeds death, and continues till the putrefactive process has commenced, is to be attributed. It is a process very similar to that of the coagulation of the blood; the only difference consisting in this, that the blood stiffens, owing to the retention by its fibrin for a sufficiently long time of its identity, while the muscles stiffen, owing to the development in them of fibrin which they did not previously contain (b).

Again, various agents which are most active in corroding certain animal tissues when they have become disorganised, as the hydrochlorate of mercury and the nitrate of silver,

(a) Notwithstanding all this, we find chemists, in the accounts of their operations on organic matters, continually using the terms membrane, nerve, muscle, and so forth, as entirely synonymous with gelatin, albumen, fibrin, and the rest. Dr. Bostock, for example, says habitually, "*membrane* is soluble in this or that;" "*membrane* has a strong affinity for the tanning principle," &c.; "the action of nitric acid on *nerve* is so and so;" "pure potash dissolves *nerve*," &c.; "the *muscular fibre* is readily acted on;" and so forth. The grave-digger in Hamlet spoke more "by the rule" in these matters—"one that *was* a woman, but, rest her soul, she's dead."

(b) That the seat of this rigidity is the muscles is obvious, since it ceases immediately upon their being divided; but Hunter, Nyström, and most late physiologists have been mistaken in ascribing it to muscular contraction, excited by what Hunter calls "the stimulus of death," as is clear from the facts, that it does not take place till some time after death, whereas such contractions should be most powerful immediately on its occurrence, and that it takes place --and that even more quickly and remarkably--in weak subjects than in strong ones. That it is not obviated by palsy, or by the division of the spinal cord, although apparently a very strong argument against the notion of Hunter, is not really so; since the supposed contractions may be conceived to be quite independent of any stimulus naturally conveyed by the nerves. It has, indeed, been suggested by some chemical physiologists, that the contractions of muscles during life may be, to a certain degree, dependant on the coagulation of their fibrin; and Humboldt, Cuvier, and others, have supported the notion that the increased cohesion of muscles, under these circumstances, is attributable to this cause. Rudolphi accordingly endeavours to amalgamate the opposed doctrines, and ascribes the

rigidity of the limbs after death to muscular contractions, "excited by a chemical operation." The "chemical operation," however, unfortunately for this *juste-milieu* hypothesis, does not take place till the susceptibility of contraction has ceased—to say nothing of the probability that such a coagulation of their fibrin, far from effecting, would be incompatible with the contraction of muscles, or of the absolute superfluity of the presumption of any such contraction to explain the phenomenon in question. It is remarkable that this rigidity is prevented by most of the causes which prevent the coagulation of the blood; a circumstance which, while it favours the presumption that it depends on a strictly chemical cause, is not at first sight easily reconcileable with the hypothesis that the latter is prevented, in these cases, by the fibrin being inadequately re-composed, after its decomposition, owing to the congested state of the radicles of the veins, since this cannot apparently have any effect in preventing the development of fibrin in the muscular tissue upon the cessation of its irritability. It will appear, however, in future that the total want of muscular contractions, which likewise occurs after death under these circumstances, can be referred only to a defective deposition, owing to excessive irritation—such as that produced by electricity, violent exercise, an intense emotion of the mind, narcotic poisons, a blow on the head, and other causes of venous congestion—of that tissue on which the irritability of the muscles immediately depends; and if we are thus compelled to admit the defective decomposition of one tissue to explain one phenomenon, it is surely allowable to suppose that of another to explain the one under consideration, and to presume that the want of subsequent rigidity results from the defective deposition of muscular tissue, which is resolved into fibrin after death, only when perfectly prepared.

with respect to those which contain albumen, oxalic acid, with respect to those which contain gelatin and nitric acid, with respect to those which contain fibrin, have no action whatever on them so long as they retain their vitality; and even the gastric fluid, which so rapidly decompose, every kind of disorganized organic matters, and not unfrequently, after death, even the very surface by which itself was secreted (a), is totally inert with respect to such matters while still possessed of vitality. Hence seeds and small animals are well known to pass sometimes through the stomach and intestines of larger animals, and parasites even to harbour there for an unlimited time, without sustaining the least injury; whereas, had their vitality once deserted them, they would have been immediately digested. Lastly, what membrane, nerve, or muscle, under any circumstances of heat and moisture, ever, while it continues organized, runs on to putrefaction; and which of the compounds, of which they are severally said to consist, under the same circumstances is capable of resisting it (b)?

Have we not, then, a right to conclude that there is in reality no ready-made osmazon, no sodo-albumen, no gelatin, no fibrin in the organized tissues of animals, but only the same elements as these compounds contain, and even associated together, as they are in them, by secretion, but held together by a power quite distinct from common chemical affinity, in a state of combination peculiar to living matter; and that it is only at the instant of the cessation of the vitality of each organized tissue, that these compounds, or reputed proximate principles—which certainly exist from the first in the unorganized tissues and fluids—are formed—at that instant when the power called chemical affinity succeeds another power, which may be called vital affinity, by which it had been previously superseded, and common chemical compounds are all that is left of that organized mass into which the elements had been before combined? It is contrary to every principle, not only of philosophy, but of common sense, to admit the presence, in any substance, of a property which is never displayed by common chemical compounds, and, at the same time, the absence of all those properties by which such compounds are known, and still affirm that the chemical nature of this substance and of these compounds is identical. Upon what circumstance, if not upon a difference in their properties, can we at any time establish a difference in the nature of bodies? We know nothing of their *Υλη πρώτη*—nothing of any one of them abstractedly; and if asked what is osmazon, sodo-albumen, gelatin, fibrin, and so forth, what could we say but that each is something which has such and such characteristics, and which, when acted on by certain re-agents, manifests such and such phenomena? It is a mere truism, then, to say that organized tissues, which have other characteristics, and which do not exhibit, under the same circumstances, the same phenomena, cannot be of the same nature as they are; and, if this be admitted, it will be evident how mistaken must be the doctrine which regards the globules said to be found—at least after the cessation of their vitality—in the several organized tissues, and which, if they exist at all, are merely particles of sodo-albumen, gelatin, &c., as organic elements, or molecules, and inculcates that it is directly in them that the aptitude for life or vitality resides. The really organic elements, or molecules, are probably, under ordinary circumstances—that is to say, while the organized being not only possesses the aptitude for life, but manifests life itself—never for one instant the same, and are certainly such as to have entirely eluded, hitherto, all our attempts to overtake them. There has, nevertheless, been generally evinced the utmost unwillingness to admit that organized matter is, in its chemical nature, distinct from such as is unorganized, and that it is held together by a power distinct from common chemical affinity. Any compromise seems to have been commonly preferred to this: and endless modifications, by the supposed vital principle, of a chemical nature presumed to be common to all kinds of matter, and of a power presumed to be in universal operation, have been accordingly proposed by chemists to account for the peculiarities of such as is organized, without their having perceived that the proposed modifications were such as, not merely to qualify this supposed common nature, but to exclude it and establish a proper one in its place, and not merely to temporize with this common power, but to admit a proper one to counteract and supersede it (c). Organized matter, as on the

(a) This action of the gastric fluid was noticed first by J. Hunter, (Phil. Trans. 1767), and has been since illustrated principally by Baillie, Adams, Home, Burns, Meckel, Haviland, Gairdner, Want, Pascalis, Cheeseman, Ségalas, Beck, Travers, Cramp-ton, Davis, and Carsewell.

(b) So striking is the attribute of organized tissues of resisting putrefaction, that it has been regarded by some physiologists, for example, Stahl, Junker, and J. Hunter, as furnishing one of the best means of de-

fining life. Such is not the case; but it is nevertheless a necessary property of the composition of a living being. Life is certainly "*Putredini contraria*;" but we cannot with propriety regard it, as Junker does, as consisting in "*illud putredini contrarium*." The resistance of common chemical re-agents is coincident with life, but not identical with it.

(c) Thus, to cite the expressions on this subject of only a few of the most celebrated chemists of the present century, Chaptal

one hand, possessed of properties which have no parallel in such as is unorganized, and, on the other, destitute of those by which the latter is characterized, must be regarded as quite distinct from it; and chemical analyses accordingly must be considered as useful in showing us, not what such matter *was* composed of while it possessed vitality, but what it is composed of afterwards (a).

describes living bodies as all subject to the influence of common chemical powers, but the effect of these, he says, "is modified by the re-action of the vital principle;" (*El. of Chemistry*, 1800). Dr. Thomson speaks of these powers as being, in the living body, not super-added by, but "the servants of a superior agent, which directs them so as to accomplish always one particular end;" (*System of Chemistry*, 1817); by Dr. Murray, the parts of the living body are described as common chemical compounds, the result of common chemical affinities, "which have been exerted merely under peculiar circumstances;" (*System of Chemistry*, 1819). Dr. Dewar observes that the materials of which living bodies consist, are not in the least withdrawn from the influence of the chemical laws which belong to other matter, but "new laws are superadded by which the effects of these common laws are in the most important manner changed;" (*Ed. Med. and Surg. Journ.* 1821); and Dr. Henry, while he admits that there is, in the living body, "a directing principle superior to, and differing from the cause which has been termed chemical affinity," with singular inconsistency at the same time presumes, that "the processes of chemistry, performed on dead animal matter, exhibit its proximate principles in a state identical with that in which they exist in animal structure;" (*El. of Exp. Chemistry*, 1823)—as if a directing principle, confessedly different from common chemical affinity, could be conceived of, as producing nothing but common chemical compounds. It is needless to multiply examples of this attempt to reconcile the simultaneous existence and action of contradictory powers—this "vital principle," this "superior agent," these "peculiar circumstances," these "new laws," this "directing principle," are only other words to express a new power, which not only restrains and controls, but opposes and dispenses with common chemical affinity; and which, as giving rise to forms of matter quite distinct from all others, is justly entitled to be regarded as entirely *sui generis*. Mr. Mayo considers it as "highly probable that the laws of chemistry, and the property which controls the affinity of matter in living bodies, will prove eventually to be identical." (*Outlines of Human Physiology*, 1827). Perhaps they may—but in the meantime we must be allowed to consider them as perfectly different from each other, since it is by

their fruits only that we know either, and the fruits of the two are certainly—as far as they have been hitherto ascertained, as different as can well be imagined.

(a) Berzelius is among the few chemists—for he is a physiologist as well as a chemist—who have admitted this almost self-evident fact. "Les elements," says he, "paraissent obéir dans les corps vivans à d'autres lois que dans les corps morts"—(*Traité de Chimie, par Jourdan*, 1829)—not newly modified, but other laws—but among professed physiologists the admission has been almost universal. Thus Rudolphi expressly states that chemistry is able to investigate only the lifeless remains of organized beings. (*Grund. der Physiol.* 1821). Dr. Barclay—one of the strongest advocates for the existence of a vital principle—concedes to it with respect to chemical affinity, not only, like Choptal, a modifying, but a subversive influence; and remarks that the combinations of organized matter "not only indicate a species of chemistry unknown to man, but evidently imply a species of chemistry whose modes of operation are equally beyond his powers to imitate, and his powers to comprehend." (*On Life and Organization*, 1822). Adilon again speaks of vital affinity, contrasted with common chemical affinity, as "une force toute opposée;" and very justly demands, "les molécules qui forment les solides du corps humain, étant associées en vertu d'une affinité spéciale, dite vitale, et que les chimistes n'ont pas en main, comment ces chimistes pourraient ils prétendre faire une analyse de ces solides? Ils ne font que les détruire." (*Physiol. de l'Homme*, 1823). It may be noticed as singular, also, that Dr. Pritchard—one of the most successful opponents of the vital principle doctrine—still quite coincides in opinion with Dr. Barclay, on the subject in question, and maintains that "the component materials of the dead and living body are not existing under the same chemical circumstances." (*On the vital principle*, 1829). Finally—for the list need not be prolonged—Tiedemann describes the combinations of organized solids as depending on forces proper to their bodies: and admits that it is not till after death that chemical affinities enter into play; (*Physiologie*, 1831); and a similar opinion is now entertained by almost all who are capable of forming an opinion upon the subject.

LECTURES
ON THE
PHYSICAL EDUCATION AND DIS-
EASES OF INFANTS,
FROM BIRTH TO PUBERTY,
BY DR. RYAN,
*Delivered at the Medical School, Westminster
Dispensary, Gerrard Street, Soho;
Session 1834-35.*

LECTURE XXVII.

Congenital Excess of Parts—Hypertrophies.

THE foetus is sometimes born with hypertrophy, or excessive development of organs, with supernumerary parts, or with various excrescences. The brain has been so large as to resemble hydrocephalus (Chaussier), the heart, liver, spleen, kidneys, pancreas, and other abdominal organs, the prepuce and nymphæ, have been hypertrophied at birth, and M. Duges applied a ligature in two cases on a prolongation of the hymen beyond the vulva.

Infants have been born with six, eight, or ten fingers and toes on each extremity. M. Duges saw seven and eight fingers on each hand; and M. Gardien the usual number of fingers and toes doubled. Deformities of this kind are hereditary in some families. I have usually seen two thumbs on each hand, and on one hand only.

It is on record, that one individual had two tongues, two hearts, two spleens, &c.

When supernumerary fingers are attached by a simple pedicle, they may be removed with safety, as attested by M. Duges, who performed the operation; but if the supernumerary part be united by a complete articulation it should be allowed to remain.

Excrescences and tumours may exist on any part of the body at birth, and are erroneously ascribed by the vulgar to the influence of the maternal imagination. Some of these may be removed by ligatures; others are beyond the means of art.

It sometimes happens that a fungus forms after the falling off of the umbilical cord, which bleeds freely. This varies in size and is pedunculated. It is accompanied by a purulent or sanguineo-purulent discharge, and has been mistaken for hernia-epiplocele. Some practitioners advise a ligature, others cauterization with nitrate of silver, and more excision. In most cases I have found a saturated solution of alumen, 3s to the 3j of distilled water, with a compress of soap plaister and a bandage sufficient. I shall more fully describe excrescences when enumerating diseases of the skin.

Congenital defect—Diminution, or destruction of Parts.—Every part of the body may be defective or absent at birth. An infant may be born with one or both eyes or ears want-

ing, one of the thoracic or abdominal organs, an arm or a leg or both absent, or have one hand or foot, or one very much diminished in size. The heart, the greater part of the brain, an eye, ear, or the genital organs, are sometimes absent. M. Dumas describes a case of a person who had no legs, but the feet articulated with the thighs at the knees. I have seen a person whose upper extremities were wanting, and who had a small tubercle like a wart on each shoulder. I have seen a tumour of this kind over the site of the genital organs. Others have observed examples of absence of the thighs and legs, and the arms and forearms, and the hands and feet naturally developed. (Duges). This learned author also saw an infant whose arms terminated at the elbow. Though the greater number of these deformities are incurable, we ought to supply the want of organs when possible. Thus we see persons with an artificial eye of glass, an ear or a nose of silver, a steel substitute for a hand. Captain Derenzy has described a variety of instruments for persons who have lost one hand, in his work entitled "Enchiridion." A great many deformities of club feet, which are so detrimental to locomotion, progression, or walking, may now be remedied by art; and so great is the advance of science in this particular, that indeed I have not seen a child with perfect club feet for some years. This is a vast improvement. It is deplorable to witness a fine athletic man hobbling his weary way, whose health is injured, and whose life is shortened by the ignorance of the medical practitioner who was present at his birth. Even the illustrious Byron could not forget an infirmity, which, had he known it was, perhaps, the result of medical ignorance, he would have satirised in imperishable stanzas. There are some forms of clubfoot which cannot be remedied; but a great number of cases admit of relief. This must be obvious when we bear in mind the facility there is of moulding into proper shape the imperfectly ossified bones of a new born infant. I have now treated six cases successfully. Different parts of the foetus may be destroyed by gangrene during intra-uterine existence. This is proved by the detection of the gangrenous parts in the liquor amnii. (Chaussier, Adelon, Velpeau).

The extremities may also adhere to the trunk at different points. The head may be very defective.

Acephaly.—Acephalous infants appear with the greater part of the head absent. They generally survive only a few moments after birth; but there is invariably some portion of the brain or cerebellum in the base of the skull. The foetus appears a shapeless mass, attached to the umbilical cord, and contains some vessels and nerves, with a portion of the intestinal canal. In other examples the inferior extremities, with some of the viscera

and a part of the spine, but not the heart or lungs, exist. (Elben, Breschet, &c.)

In many the superior extremities, thorax, and trunk are developed, while the other parts and the head are atrophied; and these have been called by Geoffroy *crypto-cephalous* and *coecy-cephalous infants*. In all cases a portion of the head, covered with hair, is apparent; and this fact led Beclard and Duges to conjecture, that the head existed before the other mutilations took place.

In some cases the skull is flattened on a line with the face. The term *microcephaly* has been applied to this deformity. This diminution is ascribed to hydrocephalus, with rupture, or to hernia, or *hydrencephalocoele*. It may also arise from the pressure of tumours on the foetal head, or upon pressure applied to the abdomen of the mother in the first months of pregnancy, which Geoffroy has termed *thlipsencephalous*.

In other cases the pressure is applied on the face, which may be entirely wanting (*anopsy* or *aprosopy*), or it may be reduced in its inferior part (*synoty*), but it is most frequently at its superior part, the cranium at the same time projecting forwards, and the eyes approximate more or less, or unite (*synopsy*), or are confounded (*monopsy*). We sometimes observe cases in which a hydrocephalus bursts, the fluid finds its way between the bones of the face, separates them, destroys the olfactory and other nerves, and even one eye. A foetus with one eye (*monospy*) may live a few hours, but seldom longer.

Anencephalous infants are those in whom the brain is displaced or entirely absent. In some the brain and upper part of the spinal marrow are absent, and the cranium unites to the neck or cervical vertebræ; the trunk is curved, and the abdominal viscera form a kind of protrusion or umbilical hernia. *Anencephalous* infants shew very slight signs of life, according to Lallemand.

All these deformities are said to depend upon a primordial conformation (Gall), on an arrest of development (Meckel), on a local inflammation (Blandin), and on a hydrocephalus followed by rupture (Morgagni, Chaussier, Beclard, Duges, &c.) It is easy to understand that the serosity or water, as it is improperly called, may distend the brain, rupture its membranes, separate the bones of the cranium, burst the scalp, and finally escape into the amniotic fluid. The whole brain, membranes, bones and scalp are destroyed by absorption, and the base of the skull alone remains, forming the *acephaly*.

Malformation of the Eyes.—The following account of these deformities in man and animals is by Dr. Seiler of Dresden, translated from his work published in 1833, and entitled *Beobachtungen, Ursprang-icker, Bildungsfehler, &c.*

The first part of this production contains the most remarkable instances of every

species of general malformation of the eyes, as to situation, dimensions, &c. They are ranged under several heads, which are as follow:—

1. *Number of Eyes.*—Some authors, more or less ancient, have spoken of individuals who had more than two eyes; but these are not to be credited. Not so, however, of those related by Walter and Rudolphi, in which one eye occupied its normal situation, while the other was wanting. This is not to be confounded with *cyclopia*, in which both eyes are more or less joined in one, and placed in the centre of the forehead. M. Seiler proposes to call the former case “perfect monophthalmia,” and the latter “imperfect monophthalmia.”

2. *Situation of Eyes.*—The most remarkable anomaly is the cyclops (*monopsia*, *rhinencephalia*).

3. *Dimensions of Eyes.*—The globe of the eye may be too large (*megalophthalmia*), or too small (*microphthalmia*). The enlarged eye is more particularly observed in cyclopia, anencephalia, and hydrocephalia. *Microphthalmia* was first mentioned by Beer, and subsequently described by Dr. Peenitz, of Dresden.

4. *Complete want of Eyes.*—M. Seiler briefly mentions the various cases of this kind recorded. He describes one observed by Daniel of Halle, in 1765. He then gives an account of two monstrous children preserved in the Museum of the Dresden Academy; in both cases, the eyes were wanting: in the former, the orbits were only separated by a line; in the second, there was only one orbit. The different facts quoted by M. Seiler show, that we should not generally maintain that when an organ is wanting, its nerves do not exist: they also show that eyes may exist without optic nerves or retinæ, and that the different parts of the nervous system do not so much depend on each other, as that a nervous branch cannot be developed without being connected with the brain by its trunk. Kliakosch found branches of the fifth pair in monsters, in whom the trunk of that pair did not exist.

Second Part.—Particular malformations of the parts of the Eye, Eyebrows, and Eyelashes.—They may be wanting, be too short, too fine, or have a vicious direction.

Eyelids.—They have been wanting, been too short, had a vicious direction, or been separated into two lateral flaps (*caloboma palpebræ*). Children have been born with the eyelids adhering to each other, or to the ball of the eye, (*anchyloblepharon* and *symblepharon*): this, according to M. Seiler, is a consequence of intra-uterine ophthalmia. In cyclops, the four eyelids are united round the one orbit.

Lachrymal Organs.—Their absence is often synchronous with that of the eyes; some

times one or other part of the lachrymal passages alone is wanting.

Muscles of the Eye.—When there is no eye, muscles are rarely seen. Supplementary muscles of the eye have been observed.

Nerves of the Eye.—Generally wanting when the eye is wanting. M. Seiler, however, found them all in an eyeless child. Sometimes the different parts of a nerve exist, but are separated from each other by want of immediate parts. At others, the neurilemma exists, but is not filled in the nervous pulp.

Sclerotic and Cornea.—The former has remained transparent, and not been distinctly separated from the cornea, which in some cases has been replaced by the sclerotic. The cornea is sometimes too small or opaque over a varied extent. Neophytes also exhibit webs, excrescences, or fungous tumour of the cornea.

Choroid, Corpus Ciliare and Pigmentum.—A case of absence of the choroid recorded by Klinkosch, is the only one known. Congenital division of the choroid has been more frequently observed, generally accompanying a similar defect of the iris. The pigmentum is variously abundant; its absence constitutes *leucæthiopia* or *Albinism*.

Iris, Pigmentum, Pupil and Pupillary Membrane.—Half or less of the iris has sometimes a different colour from the rest of the membrane. The pupil may be too small, too large, misshaped, wrongly placed. There may be two pupils in one eye—an anomaly more frequently seen in cyclops. The pupillary membrane is sometimes existent after birth. Congenital division of the iris, called *coloboma iridis*, by Walther, consists in an imperfect development of that tunic; the division commonly extends from the pupillary edge towards the lower part of the ciliary edge, and often corresponds with a similar division of the choroid and retina. The iris is sometimes altogether wanting; eight cases of this kind are cited by the author. He might also have quoted one from the *Archives Generales*, vol. xxv, p. 405, and from the *Journal d'Ophthalmologie*, vol. i, p. 490.

Retina.—Except in the Magendie's case, this nervous expansion has been found wanting on every occasion where the optic nerve is wanting. The retina has been sometimes observed to be turned backwards at its lower part; this accompanies congenital division at the iris and choroid. The nervous pulp of the retina may be also too liquid.

Aqueous Humour.—Has been too abundant, or turbid in neophytes.

Lens and its Capsule.—Lenticular and capsular cataract, are the only congenital diseases of these organs. In cyclops, two lenses are sometimes seen in one eye. M. Seiler gives an instance of its total absence.

Vitreous Humour and Circle of Zinn.—The vitreous humour is found too fluid, too copious or turbid. In a child five weeks old, Professor Ammon saw it wanting altogether in one eye, and too large in the other. In the former eye there was a ciliary ligament, but none in the latter; in this case there was an immense hydrocephalus.—*Dr. Ryan's Med. and Surg. Journ.* 1834, vol. vi.

Congenital Dropsies.—The term hydropsy, or dropsy, is applied to a collection of serous fluid in the three splanchnic cavities, the head, chest, and abdomen, and also when it exists in the eye, scrotum, spine, ovary, and other parts of the body, as in those cases when it is encysted or sacculated. The most common congenital dropsies of new-born infants are hydrocephalus, or dropsy of the brain, hydrorachitis, or dropsy of the spine, hydrocele, or dropsy of tunica vaginalis of the testicle, infiltration of the scrotum, hydrothorax, or dropsy of the chest, ascites, or dropsy of the abdomen, and anasarca, or general dropsy of the cellular membrane under the skin, which may occupy the whole body. The best and most elaborate account of dropsy in our language, will be found in Dr. Copland's Dictionary of Practical Medicine, a work that ought to be in the possession of every medical student and practitioner.

Congenital Hydrocephalus.—This disease is of rare occurrence, and is said to be caused by an original laxity of the brain, by a defect or arrest of development of this organ, during the first months of intra-uterine life, by the pressure of tumours on the head, or by the infliction of injuries on the abdomen of the mother, among which we include *tight lacing*. The disease is sometimes of frequent occurrence in some families. Underwood described six infants of the same father who were affected with it, and those died about the age of two years. G. Armstrong reports that he frequently examined the heads of different infants of the same family; and supposed that it was hereditary. This last opinion remains however to be confirmed.

The immediate or proximate cause of dropsies is, an increased exhalation, and a diminished absorption, so that the effused fluid accumulates. The equilibrium between the functions of the exhalent and absorbent vessels, essential to health, is destroyed, and an effusion of serous fluid is the result. The ancient writers considered debility the cause; while most of the moderns are of opinion there is a determination of blood, a congestion, or a subacute inflammation in the serous membranes, which causes the effusion. You will find ample information on the pathology of dropsy, in Dr. Copland's Dictionary of Practical Medicine, to which I refer you.

It is difficult to comprehend how either of these causes can affect the foetus in utero; but certain it is, that there are congenital dropsies.

Hydrocephalic infants have been destroyed by the compression of the pelvis of the mother during labour—a fact attested by numerous obstetric writers. M. Capuron relates a case which he attended with professor Marjolin, in which they were compelled to puncture the head, when three pints of fluid escaped. The mother had received two violent falls during pregnancy. A drawing of a hydrocephalic infant was lately shewn at the Medical Society of London. The mother had rupture of the uterus, and gastrotomy was performed unsuccessfully.

The infantile head is liable to great compression, when the amniotic fluid or waters escape prematurely, or when it presents in a preternatural or wrong direction. In such cases, the circulation of blood in the scalp and head is impeded, and the infant is born with the head swollen, or it may be killed by the pressure. The infant is still-born, the face livid, and unless the navel-string is allowed to bleed from one to four drachms or teaspoonsful, and other resuscitating means employed as formerly mentioned, the congestion of the brain will destroy it, or predispose to hydrocephalus. The scalp is often tumefied in such cases, and is to be relieved by cold applications, and when these fail, the effused or extravasated blood may be removed by an incision as already described. Tedious or difficult labours are therefore highly dangerous to the infant as well as to the mother; they should be always abridged and speedily obviated by medical assistance. In such cases, contusions, tumefactions or infiltrations appear after birth; and unless removed by cold and resolvent applications, leave a congested state of the brain, which sooner or later, more especially if the head be inordinately developed, or when dentition commences, will predispose to effusion, or “water in the head.”

There are other soft tumours and extensive congestions on the scalp, especially over the occiput, which are congenital, and do not induce hydrocephalus. Ruysch describes a tumour as large as a foetus, connected with the occiput, the fluid in which communicated with that contained in the ventricles of the brain. He also remarked, that such tumours do not always consist of fluid, but partly of solid cartilaginous or fleshy parts. Wepfer describes a similar tumour on the occiput of an infant who lived for some years, was seized with dysentery and catarrhal fever, and died, after convulsions and paralysis of the left foot. On examination it was discovered, that the tumour communicated with the brain through a round aperture in the occipital bone. The ventricles of the brain contained more than a pint of sanguinolent serosity. Soft tumours may exist on any part of the head, and be connected with the brain. I remember a case of an infant in the Edinburgh Infirmary, who had a round

tumour attached to the root of the nose, and this was tapped twice, but death followed. On dissection, it was discovered that this tumour communicated with the ventricles of the brain.

Hydrocephalus may be accidental as well as congenital. It is often caused after birth, by falls or blows on the head, by a repression or sudden disappearance of cutaneous eruptions, small-pox, measles, scarlatina, itch, &c., &c., by dentition or teething, by whooping-cough, inflammations of the organs in the chest, by irritation in the bowels, from worms, ulceration, disease of the liver, &c.

When fluid is effused into the ventricles, or between the membranes of the brain, it will cause compression of the brain, and derange or suspend its functions; a train of nervous symptoms follow, which we observe, when hydrocephalus supervenes after birth.

At first the infant evinces a sense of pain and weight in the forehead, it is giddy, dull, and disposed to lay down its head; it soon falls into a state of stupor or insensibility, its intellectual faculties are changed and deranged, the pupils are dilated and gradually lose their sensibility, the pulse becomes slow or rapid, the appetite is lost, and the alvine evacuations and urine are depraved. In a short time the cheeks become florid, the eyes dull, vision diminished or lost, the scalp hot, the forehead prominent, the nose depressed, and sometimes thin, the bones of the head and nose become soft and transparent, the eyes become prominent, the power of speech and of motion is suspended. All these symptoms are caused by the pressure of the fluid on the brain, which prevents that organ from supplying innervation to the different parts in the body. Compression of the brain, caused by depressed fracture of the cranium, or by apoplexy, produces partial or total suspension of sensation and voluntary motion. Van Swieten describes the case of a man, aged thirty years, who laboured under hydrocephalus from infancy, whose head was so large, that the muscles could not support it. His body was no larger than that of a child of ten years of age, was supported in the erect position with pillows. Nevertheless he enjoyed the functions of his senses, but was remarkably stupid. There was a lachrymation from one or both of his eyes. He was almost constantly uttering plaintive cries. I have seen a case at Limehouse, with Mr. Warden, of a child six years old, who was affected with congenital hydrocephalus; it was nearly deprived of the functions of the senses of vision, hearing, taste, smell, and touch, and entirely of the power of motion. It was supported in a chair with pillows, and its chin rested on a bar, without which, the head could not be kept in the erect position. The eye-lids were partially closed, the hearing very dull, the head very much enlarged.

the forehead prominent, the *æces* and urine discharged involuntarily. Littre, gives the history of an infant affected with hydrocephalus for two years, which slept very little, and scarcely ceased to cry the whole time. Such cases were long considered incurable, but it will immediately appear that this opinion was erroneous.

When the disease advances there is loss of vision, hearing, and memory, and sometimes the sufferer becomes epileptic or paralytic. Finally, coma, lethargy, or convulsions terminate the scene.

In some cases the effusion takes place gradually, the symptoms are obscure, the disease is protracted for a long time; and death is preceded by stupor only.

Congenital hydrocephalus is most probably the result of inflammation of the membranes of the brain (meningitis) during intra-uterine life, or of a defect of conformation which cannot be easily detected, and which may be compared to a kind of nutritive hypertrophy of the brain. The fact of the excessive development of the brain, hair, and cranium, in hydrocephalous infants, warrants the conclusion. The disproportionate size of the head to the development of the rest of the body, and the luxuriant capillary growth in such infants, confirm the validity of this opinion. Infants, after birth, with such peculiarities, are predisposed to hydrocephalus. In these the bones of the head have acquired great size and thickness.

There are different varieties of congenital hydrocephalus. The disease may appear in the embryo, and obliterate the whole brain, or distend it into a membrane, or even destroy the bones of the skull. In such cases there is nutritive hypertrophy, which supplies a superabundance of blood in the brain, augments the secretion of its membranes, and causes effusion. If we admit there is want of nutrition, and an arrest of development in monstrosities, we must also allow the existence of excessive development.

Drs. Monro, Shearman, and others, attribute the disease, after birth, to debility.

Congenital hydrocephalus consists in the effusion of serosity into different parts of the brain, or between its membranes. The fluid is contained in the ventricles of the brain, between the arachnoid membrane and the brain, the pia mater and dura mater, but never between the last and the brain. The position of the effused fluid led nosologists to divide hydrocephalus into two species, *external*, hydrocephalus externus; *internal*, hydrocephalus internus, hydrencephalus. (Monro tertius).

The effusion may be general or partial. In the latter the serosity accumulates in one or both ventricles; the tumour may be circumscribed in any portion of the arachnoid, but generally towards the summit of the head, at sutures, fontanels or occiput. The quantity of fluid may vary from a teaspoonful—

3j—to thirty-five pints. When a large quantity is effused the convolutions of the brain may be so expanded as to appear like a membrane. Tulpius relates a case in point; and adds that the patient retained the enjoyment of his intellectual powers until death—a statement opposed to physiology and pathology; and I should declare—an unfounded one. I have often observed illustrations of vast enlargement of the head, and extension of the convolutions in the brain, but I never witnessed one in which the intellectual powers were not greatly affected or diminished. When the effusion takes place suddenly, the bones of the cranium are separated, and the fontanels enlarge; but when it is effected slowly, the bones will sometimes present no trace of sutures, and acquire a remarkable size and thickness. Lassus states that they have been found so large and so thick as to be mistaken for the bones of a giant. Such was the state of the cranium of a child of nine years of age, described by Duvernay; and of the left parietal bone preserved by Ruysch as a curiosity, which was of such a prodigious size that it could cover the whole head of an adult.

The disproportionate size of the cranium, while the bones of the face remain in their natural state, constitutes the pathognomonic sign of chronic hydrocephalus. The disease has so advanced in the foetus in utero, that the fluid has destroyed the substance of the brain, the membranes, bones of the scalp, and their integuments, and burst into the cavity of the amnios, or that membrane which surrounds the foetus in the womb.

Hydrocephalus may advance rapidly or slowly in the foetus before or after birth. It seldom occurs after the eighth year, but may even at the adult period of life. But when it attacks children after the eighth year, or persons at puberty or the adult age, the quantity of effusion is comparatively small, and varies from a drachm to two or three ounces. It may remain stationary, and continue to a very advanced age. It was well observed by Camper, that infants, the bones of whose heads were not separated, lived longer (to adolescence or later) than those whose fontanels (openings of the head) were large, and the sutures of whose bones were separated. Van Swieten narrates the case of a man who survived for forty-five years. It was generally supposed that death was, sooner or later, inevitable in cases of chronic hydrocephalus; but the improvements in therapeutics during the present century disproves this opinion, as the disease has been cured by paracentesis cranii (tapping of the brain), by Dr. Conquest and Mr. Russell, whose reports will be given when I describe the treatment of the disease. Hitherto, it too frequently defied our resources, and when of long duration was deemed incurable.

It may exist in the new-born infant, according to Billard, without the presence of

any morbid symptom. It also comes on insidiously in children, whose intellectual powers are active, who have large heads and a great growth of hair, whose instinct and mind are precociously developed. In such the brain is inordinately developed, the cranium is large, and the hair luxuriant; and if the infant thus constituted receive falls, blows, or suffer much from dentition, hooping cough, inflammation of the lungs, irritation of the bowels called infantile remittant fever, worm fever, fever from the teeth, the ataxic or typhus of foreign writers, the irritation induced by any of these diseases will increase the flow of blood to the head, and predispose to hydrocephalus. So also with precocious mental exertion, as when parents and teachers most unwisely attempt to make children, as soon as they can speak distinctly, paragons of perfection in learning and the sciences. Mental exertion of this kind has destroyed thousands of children. But of its bad effects I have spoken on a former occasion, when observing the moral and intellectual education of infants.

Hydrocephalus may be erroneously supposed to exist in cases of infantile remittant fever, irritation in the intestinal canal caused by worms, congestion or ulceration of the bowels. The configuration of the head, the appearance of the hair, and the history of the case, will enable us to form an accurate diagnosis. It is a popular error in this country, entertained by parents, that every infantile disease is water in the head, vermination or worms, or dentition.

There is a disorder which resembles in many of its symptoms hydrocephalus, and which is often mistaken for it. This is designated hydrocephaloid affection, by Dr. Gooch, who, as far as I know, was the first that described it; also by Dr. Marshall Hall; and acute asthenic hydrocephalus by Dr. Darwall and others. It attacks delicate children. The symptoms are, heaviness in the head, tendency to coma, pale countenance, eyes half closed, eyelids rapidly closed and opened, pupils dilated, features relaxed, respiration slow, superior and inferior extremities cold. The causes of this disorder are diarrhoea, severe purgation or hypercatharsis, want of nutriment, or too copious bleeding by leeches, &c. It often follows ablactation or weaning. It requires to be treated with nutriment and stimulants, beef tea, arrow-root, &c., and a few drops of aromatic spirit of ammonia, or brandy in milk or arrow-root. The limbs should be enveloped in warm flannel, and their temperature raised by the usual means. If depletion, purgation, blistering, &c. were employed, the infant would perish. I lately directed your attention to two cases of this kind at the hospital, for one of which the late house-surgeon prescribed leeches, &c., a plan I countermanded, and substituted aromatic spirit of ammonia, &c., as I asked the mother, had not her

child suffered from severe diarrhoea, which was the case. In less than three hours you saw the child lively, and apparently restored to health. Cases of hydrocephalus are recorded by Quin, Cheyne, Warren, Gollis, Gooch, Callaway, and others, in which no fluid was found in the brain, though death was supposed to have been caused by effusion; and in these it may be presumed the affection was hydrocephaloid.

Dr. Darwall describes another species of this affection, which he terms acute asthenic hydrocephalus, in which the child complains of pain in the head, restlessness, &c., but all the symptoms being milder than in acute hydrocephalus. He has succeeded in curing this complaint by administering four grains of the compound ipecacuan powder (Dover's powder) every three hours until sleep is produced, and afterwards he continues the medicine twice a-day for a week.

At our next meeting I shall describe the pathology and treatment of congenital and accidental hydrocephalus.

Reviews.

Traite Complet sur la Maladie Scrophuleuse; par M. A. Lepelletier, de la Sarthe, augmenté de Notes par Van Mons. A Treatise on Scrophula, by A. M. Lepelletier, de la Sarthe, with additional notes, by Van Mons. Brussels, 1833, pp. 318.

THE original Parisian edition of this work appeared several years ago, and went through more than one edition. The germ of the treatise is to be found in M. Lepelletier's inaugural thesis, published, as well as we remember, in the year 1817. On this monograph a most favourable opinion was pronounced by some members of the faculty of medicine of Paris; in their name M. Dumeril assured the author that further researches carried on in the spirit of, and with the perseverance exhibited in, those previously made, would form the groundwork of a most useful work. So encouraged, M. Lepelletier undertook and produced the treatise now under consideration. The Parisian edition was in two volumes, 8vo.; the Belgian editor and publishers have reduced it to a duodecimo: perhaps the rage for curtailing the garments of their female peasantry sways in the arrangement of the exterior of their books. We believe, however, that the whole matter of the former is to be found in the present edition; besides which, some very pertinent notes by Van Mons may be found.

Aromatic Fumigation.

Rx. Olibani,
Mastiche,
Succini, āā 3 iij;
Styracis, calan. ite, 3 ij;
Benzoini,
Tinct. opii, āā 3 j.

Fiat pulvis.

ELEMI.

This substance possesses the same properties as the preceding ones. It is scarcely ever used, except externally; it enters into the composition of several plasters.

STORAX.

This substance was very much employed formerly, but now it is scarcely ever used, except as a topical stimulant, or in fumigations. It enters into the composition of several officinal preparations.

The dose is from gr. x—3 ss, in pills.

FLUID STORAX

Possesses stimulating properties, but is used only in dressing wounds and ulcers.

Onguent de styrax composé. P. Employed in dressing ulcers and wounds whose borders are pale and unhealthy.

L'Onguent digestif of the H. de la Ch., is composed of two parts of the ointment of storax, add one part of the oil of olives.

CHAPTER V.

MEDICINES WHICH ACT PRINCIPALLY
ON THE URINARY APPARATUS.

DIURETICS, &c.

NITRATE OF POTASS.

In large doses the nitrate of potass causes irritation to the gastro-intestinal surface; in smaller ones it is an energetic diuretic. It also appears to possess a sedative property, and it is used as a temperant as well as a diuretic in the second stage of inflammation of the urinary apparatus, in cases of jaundice, &c. It is sometimes used externally in gargles and lotions as a refrigerant.

[Nitrate of potass has been exhibited in fevers and visceral inflammations in powder or drink from time immemorial; also in dropsies, certain diseases of the kidneys, and when the urine deposits a pink sediment (lithic acid), in active hæmorrhages, mania, cynanche tonsillaris, in purpura hæmorrhagica, and in sea-scurvy. Its antiseptic property in preserving animal substances from putrefactive decomposition is universally admitted. It was given with the best effects in sea-scurvy by Mr. Cameron (Treatise on Diet), and caused a florid excretion. This writer appeals to Sir Wm Burnett, Director of the Medical

Department of the Navy, in support of his statement; and he further contends, with what justice I cannot pretend to determine, that it was from his reports Dr. Stevens received the hint of exhibiting saline remedies in yellow fever, typhus, cholera, &c. It is certain that nitrate of potass was given in barley-water, whey, and other diluents, and in powder combined with antimonials, in febrile and inflammatory diseases, long before Cameron or Stevens was in existence. T.]

INTERNALLY.—As a diuretic, gr. vj—xx in ℥j. of a mucilaginous vehicle.

As a stimulant, gr. xij—3 j. or even 3 ij.

Poudre tempéranta de Stahl. P. ℥j 3 ss.

Powder for making an ordinary Ptisan.
(Chaussier).

Rx. Potassæ nitratis, 3 ss;
Sacchari, 3 iv;
Extracti canini,
——— glycyrrhizæ, āā 3 ij;
Gummi acaciæ, 3 j.

Fiat pulvis cujus sumat cochleare minimum ex aquæ cyatho.

It is used in acute urethritis.

This powder is very useful for persons travelling.

Anticatarrhal Powder. H. Germ.

Rx. Potassæ nitratis, 3 j;
Pulv. spermatis ceti, 3 ij;
Pulveris iridis Florentinæ,
Sacchari, āā 3 j.

Fiat pulvis cujus capiat cochleare minimum secundâ quâque horâ.

Camphorated Nitre Powder. (Swédiaur).

Rx. Potassæ nitratis, gr. x;
Camphoræ, gr. iv;
Gummi acaciæ, ℥j.

Fiat pulvis in doses duas dividendus.

Diaphoretic Powder. H. of America.

Rx. Potassæ nitratis, 3 j;
Antimonii tartarizati, gr. j;
Hydrargyri submuriatis, gr. v.

Divide in chartulas v, quarum capiat unam secundâ quâque horâ.

Aperient Pills. (Swédiaur).

Rx. Potassæ nitratis, 3 vj;
Pulveris gummi acaciæ, 3 iij;
——— glycyrrhizæ,
——— althææ, āā 3 iij;
Syrupi simplicis, q. s.

Fiat massa in pilulas gr. v dividenda ex quibus sumat v ad vj ter in die.

In acute gonorrhœa, dysuria, &c.

[*Pulvis Potassæ Nitratis.* (Ph. Nosocom. Edin.)

Rx. Potassæ nitratis,
Sacchari purif. āā 3 iv;
Pulv. gum. acaciæ, 3 j.

Misce et divide in doses xxiv. T.]

Nitre ought to be combined with some

mucilaginous substance, as in this formula, though it is often ordered in saline and diaphoretic mixtures.

Boluses used in Cough. H. de Montp.

Rx. Potassæ nitratis, gr. xij;
Pilulæ cynoglossi, gr.;
Conservæ rosæ, ℥ij.

Fiant boli duo horâ somni capiendi.

An Antiphlogistic Drink. H. of Germ.

Rx. Potassæ nitratis, ʒj;
Decocti hordei, Oij;
Syrupi aceti, ʒj.

Misce cyathus singulis horis pro dosi sumendus.

In inflammatory fevers.

Diuretic Ptisan. H. of Italy.

Rx. Potassæ nitratis, ʒij;
Oxomellis scillæ, ʒss;
Decoti radicis asparagi, Oij.

Misce sumat æger cyathum sæpe in die.

An Emulsion of Nitre. H. of Eng.

Rx. Emulsionis amygdali, ℥ij;
Potassæ nitratis, ʒj.

Fiat emulsio, cujus sumat unciam singulis horis.

In inflammations of the genito-urinary organs.

In the *Emulsion nitrée* of the military hospitals, the quantity of nitre is three times greater.

Camphorated Ptisan. H. of Italy.

Rx. Potassæ nitratis, ℥j;
Camphoræ, gr. viij;
Sem. melonis, ʒij;
Aquæ fontanæ, Oij.

Cola et adde,

Sacchari purif. ʒij.

A wine-glassful may be given every two hours, to which a little lemon juice may be added.

[*Mistura Potassæ Nitratis.* (Pharm. Nosocom. Edin.)

Rx. Potassæ nitratis, ʒj;
Aquæ fontanæ, Oij.

Solve et adde,

Acidi acetici, com.

Syrupi simplicis, āā ʒiss.]

Mixture Rafraechissante. H. of Germ.

Rx. Potassæ nitratis, ʒss;
Aquæ, ʒv.

Liqua et adjice,

Aceti,

Syrupi aceti rubi idœi, āā ʒj.

Fiat mistura, de quâ capiat cochl. mag. secundâ quâque horâ.

Potion of Nitre. H. de la Ch.

Rx. Potassæ nitratis, gr. xvij;
Decocti, ʒiv;
Syrupi quinque rad., ʒj.

Fiat potio cujus sumat cochleare magnum singulis horis.

The dose of nitre is sometimes carried to 3 or 4 grains during the day.

The *Potion apëriente* of the H. des Vèn does not differ much from the above. It is composed of ℥j of nitre, ʒj of the syrup of five roots, and ʒv of the decoction of the same ingredients. Sometimes the syrup is replaced by the oxymel of squills, and in some cases, ʒiv of the acetate of ammonia is added.

In the *Potion diuretic* of the Hôt. D., the vehicle is white wine; and the dose of nitre is carried to ʒss, in Oij of liquid.

Antinephritic Mixture. H. of Italy.

Rx. Petal. papaveris, ʒvij;
Aquæ, Oij.

Coque ad ʒviij, cola et adde,
Potassæ nitratis, ʒj.

Misce.

Sumat ʒij, pro dosi, mane nocteque, ex cyatho decocto lini.

It is used with advantage in acute affections of the urinary apparatus.

Julep of the Nitrate of Potass. H. of Eng.

Rx. Nitratis potassæ,
Acidi nitrici alcoholiz. āā,
ʒij;
Syrupi limonum, ʒiv;
Aquæ menthæ, ʒxss.

Misce.

Capiat ʒj, bis vel ter in die.

EXTERNALLY. ʒj, ad iv Oj of water, in gargles, lotions, fomentations, &c.

Refrigerant Gargle. H. of Germ.

Rx. Potassæ nitratis, ʒij;
Decocti hordei, Oj.

Solve et adde,

Mellis rosæ, ʒij.

Misce.

Refrigerant Enema. H. of Germ.

Rx. Potassæ nitratis, ʒss;
Decocti lini, ʒv.

Solve et adde,

Olei lini,

Oxymellis simplicis, āā, ʒj.

Fiat enema.

Fomentation. H. of Italy.

Rx. Potassæ nitratis, ʒij;
Ammoniaë muriatis, ʒij;
Aceti, Oj;
Aquæ fontanæ, Oiv.

Compresses dipped in this liquid are applied to contusions, ecchymosis, &c. They should be renewed every hour.

[Equal parts of nitre and muriate of ammonia dissolved in ten or twelve parts of cold water, will answer the purpose of the above. T.]

SUBCARBONATE OF POTASS.

In large doses, and concentrated, it is a corrosive poison; in smaller ones, and in a proper vehicle, it is an excitant of the mucous membrane of the intestines, and a pow-

erful diuretic. It is employed in cases of gravel and other calculous affections, depending on a superabundance of uric acid; in passive hydrops, serofula, the gout, &c. It is used also in effervescent draughts. (*Vide Carbonic Acid.*) Externally it is sometimes employed as a rubefacient.

Subst. incamp. Strong acids, lime water, the sulphates of magnesia, copper, zinc, iron, alum, the hydrochlorate of ammonia, the chlorides of mercury, the nitrate of silver, the tartrate of antimony, &c.

INTERNALLY. Grs. x—3j, in a proper mucilaginous vehicle, or in white wine.

Poudre gommeuse alcaline. P. Grs. xij— \mathfrak{D} j and more, progressively.

Diuretic Ptisan. Hôt. D.

Rx. Potassæ subcarbonatis, 3j ss;
Saponis duri, 3 ss;
Potassæ nitratis, \mathfrak{D} j;
Gummi acaciæ, 3 v;
Infusi baccarum juniperi, Oj.

Fiat mistura, cujus sumatur cyathus, pro dosi.

Used by M. Récamer, in treating hydrops. It may likewise be used in gravel.

Tisane Alcaline de Mascagni.

Rx. Potassæ subcarbonatis, 3ij;
Aquæ, Oij.

Solve.

To be taken during the twenty-four hours, a spoonful at a dose, sweetened with the syrup of gum.

Recommended in chronic pneumonia.

Solution of the Subcarbonate of Potass. H. of Eng.

Rx. Potassæ subcarbonatis,
Aquæ destillatæ, āā p. e.

Solve potassam in aquâ, et per chartam cola. Gut. x ad 3j, sumat ex vehiculo apto.

As an absorbent, stimulant, and diuretic.

Absorbent Potion. H. of Germ.

Rx. Liquoris potassæ subcarbonatis,
Magnesiæ subcarbonatis, āā 3j;
Tincturæ cinnamoni, 3ij;
Aquæ, 3vss.

Fiat potio, cujus sumat cochleare tria, post cibum.

Julep of the Subcarbonate of Potass. H. of Eng.

Rx. Liquoris potassæ subcarbonatis,
3 ss;
Aquæ menthæ, 3 viij.

Misce.

3ss ad j, bis vel ter in die, ex vehiculo apto.

Potion Savonneuse. H. of Germ.

Rx. Liquoris potassæ subcarbonatis,
3 ss;
Olei amygdali, 3jss;
Aquæ, 3x;
Syrupi hordei, 3j.

Misce.

Sumat cochleare singula semihora.

In cases of poisoning by arsenic.

EXTERNALLY. As an excitent, or even rubefacient, q. q.

As an antipsoric.

3ij in frictions.

Liquor de Lous-carbonate de Potasse. P.

In lotions.

(To be continued.)

REFORM IN THE COLLEGE OF PHYSICIANS.

To the Editor of the Original London Medical and Surgical Journal.

SIR—Will you allow a subscriber of your's, during the last seven years, a corner in your ably conducted and most independent Journal?—The proposed reform in the College of Physicians, of abolishing the distinction of grades is judicious, though it comes rather late, as there is no doubt but Mr. Warburton's bill would effect this. I cannot, however, understand how the College could license physicians who have not graduated as doctors, without infringing on the rights of the universities. If this were done, there would be an abolition of the doctorate. I cannot admit the soundness of such policy. I allow the medical education is much better in London than at our universities; but the preliminary education of students at Oxford and in London differs *toto cælo*. Every one will acknowledge, that a good general education is indispensable to medical practitioners; indeed all the witnesses before the medical committee at the House of Commons agreed on this point. Then comes a question, Have the medical students of London or the provinces received a proper preliminary education? I should fearlessly answer in the negative. Who will dissent from the poet, who says—

“ 'Tis education forms the human mind,
Just as the twig is bent, the tree's inclined.”

The proposed wholesale manufacture of physicians by the College, appears to me to be a set off against the rival institutions at Lincoln's Inn Fields and Blackfriars. It would wonderfully augment the funds of the College, but must eventually destroy the once respected degree of doctor, and before half a century demolish the College itself. But it is rumoured that the College is to grant degrees. This will be an anomaly never equalled. Some three or four gentlemen usurping the rights of universities! I question much whether the legislature will consent, though the present government might; and even this I consider very doubtful.

There is one thing certain, that the College must set its house in order. What a pity it neglected to do this a century ago! It is exactly in the same position as the old

Faculty of France, with which you so aptly compared it on a late occasion; but I, for one, think its case hopeless—*Nous verrons*—

Your's, obediently,

IATROPHILOS.

[There are so many rumours afloat about the intended reform in the Royal College of Physicians, that one half cannot be true. We know, however, that great changes have been proposed by the junior fellows, to which the senior would not consent. The reason is obvious. The few, perhaps the half dozen, who bask in the smiles of court, cannot appreciate the real state of opinion; the many who are clothed in scarlet gowns, and who are not exhausted by practice, take a different view of things. There is one thing certain, that unless the College make the most extensive alterations or reforms, its fellows and members will be annihilated. There must be some common sense amongst the fellows, though their past conduct too clearly shews it is trifling.—ED.]

THE BEST MODE OF ADMINISTERING
OIL OF TURPENTINE.

To the Editor of the Original London Medical and Surgical Journal.

SIR—In the last number of your truly scientific Journal you describe the best mode of exhibiting the oil of turpentine. If not out of place, would you be so kind as to receive a remark on the same subject from an old pupil, and to give to the consideration of your numerous readers the following formula?—

R_x. Olei terebenth., 3 iss vel 3 ij;
Magnes carbonat., 3 j;
tere et adde,
Aquæ menth. sativ., 3 v;
Syrup. limonis,
Spirit lavend. comp. āā, 3 ij.

Misce et divide in haust. iv, capt. j, ter quotidie.

This formula I have given with unvaried success for many years in gout and rheumatism, even to those who were previously disgusted by the taste and smell of turpentine, and also to those who, from acidity, could not retain it in any other form on their stomachs, (the violent chemical action that takes place on the admixture of turpentine and acids is familiar, though incomprehensible, to most medical men), being the cause in the greater number of instances why it is rejected. Some time ago, you made mention of something of the kind recommended by a French writer, as a novel mode of exhibiting turpentine. Now, I beg leave to say, that the Frenchman was forestalled by a pupil of your's, who prescribed the above formula, nearly two years ago, for Mr. Midgley, an eminent chemist in the Strand, who mixed his own potion and swal-

lowed it, and to whom your pupil refers you as his authority; and, if required, many more such references can be given by

Your's, most respectfully,

J. M. D.

Clapham, February 8, 1835.

PRESENT STATE OF LUNATIC ASYLUMS.

To the Editor of the Original London Medical and Surgical Journal.

[THE following letter, addressed to Sir Robt. Peel, Bart., on the present state of Lunatic Asylums, deserves the serious consideration of every medical practitioner, for all must admit that the present medical commissioners of the insane were badly selected, as they had little if any experience in treating those unfortunate beings labouring under mental alienation. They have not proposed any improvements in the treatment of insanity; they are controlled by the magistrates or lay commissioners to a shameful extent—country gentlemen, half-pay military and naval officers, &c. &c.]

We insert this document as the friends of humanity, and with the ardent hope that some of our influential readers will advise the Legislature or Government to improve the commissioners of lunacy. The medical part of these should consist of individuals who have devoted themselves to the study of mental disorders, and who from experience would be able to suggest improvements in the moral as well as the medical management of the insane. The present commissioners, "all honourable men," are the nominees of certain parties, but not one of them had sufficient knowledge of mental disorders before his appointment.]

To the Right Honourable Robert Peel.

SIR—There are duties which the more fortunate part of men owe to misfortune, and the history of your public as well as private life are sufficient to satisfy every reflecting mind that you are animated by this generous and exalted spirit. These duties you have in many instances performed with exemplary perseverance, wisdom, and humanity, and as a proof of this statement the revision of the criminal code will, I am persuaded, be regarded by your countrymen as a memorable and lasting illustration of your liberality and love of justice. You have seen that the virtuous as well as the vicious and abandoned may come within the grasp of these laws, and hence your anxiety to purify and simplify them. The ignorant are in these days instructed and taught to look forward to a better state. The slave has also been attended to and rescued from oppression, thralldom, and difficulty, as far as his intellectual improvement will admit of; but to the aid of those labouring under mental aberration—unquestionably the most unfortunate of the human species—no remedial hand, sufficiently powerful, has yet been

duly extended. Let me, therefore, implore your assistance in cleansing the Augean stable, and thereby directing the voice of humanity towards the relief of these our unfortunate and oppressed fellow creatures. Genius, mental aberration, and virtue, are often closely allied, and it becomes singularly humiliating to observe some of the most elevated minds not only overturned by these powerful susceptibilities, but degraded, trodden on, and insulted under this awful dispensation, as the consequence of the imperfection of the system of treatment to which they are subjected, combined with the apathy and cupidity of their immediate friends, who often neglect to provide or even grant them the use of their own resources, in contributing to their comfort and restoration to mental health. Those unfortunately labouring under this malady have as it were no protector, and are thus often placed at the mercy of the most unfeeling and rapacious part of human nature; and in this point of view the immediate friends of those so lamentably afflicted are not unfrequently to be regarded, because no steady efforts are enforced for the recovery of their deranged relatives, and when that event, their restoration to mental health, becomes improbable, no adequate attention due to the misfortunes and rank of the individual is directed to their comfort and wants. Nothing seems so anxiously thought of in many instances as the possession and division of the property of the deranged; and we may here remark that the present system of licensing and inspecting these establishments, instead of remedying these evils, has contributed to perpetuate them. The commissioners, with their late secretary, did no good to these unfortunate objects of their care; and mad-houses are never likely to improve while their superintendants are allowed to derive large emoluments from their professional intercourse with such receptacles. Among the traders in this line there are medical men, who are well known as participating in the emoluments of the mad-house keepers. What chance can a patient have of recovery under such a circumstance? Their superintendence, instead of being regarded as a system of virtuous and humane inspection, should be designated a system of corruption, negligence, and vile deception. The evils which were unfolded by the inquiries into the state of lunatic establishments afford ample proof of the careless, abandoned, and vicious measures which had extended themselves to these institutions. What could be expected when the guardians of the deranged were the retainers of the proprietors of lunatic establishments, and fed and supported as it were by their iniquities? It would well become the enlightened mind of the Lord Chancellor to direct his attention to this interesting subject of inquiry, in order to remedy the evils with

which the unfortunate objects of his care are afflicted. The most unprincipled scoundrel has a jury and a judge to aid his cause, but those labouring under mental derangement have neither friend nor assistant, but are in many instances exposed as it were to the full force of the pitiless and pelting storm. It may be here observed that there is a facility in depriving a fellow creature of his liberty under the imputation of mental aberration, which is altogether extraordinary in a country such as this. The certificate of a single respectable medical man should be sufficient to authorise temporary coercion when the patient unfolds propensities dangerous to himself or others, but such certificate should not, as at present, justify protracted confinement in a mad-house, or being sent to one, until deliberate inquiry shall take place. Before a step of such paramount importance is concluded, a solemn inquiry should be instituted, and that inquisition should consist of three or five, with powers to decide the question of sanity or insanity, and when insane, whether the individual so found should be sent to a mad-house or treated privately. With these preliminary remarks I now beg to place the following facts before you, as they are founded in many years' intercourse with establishments for the reception of the deranged, and are strongly corroborative of the necessity of erecting county asylums for the reception of those labouring under mental aberration. The patients sent to the lunatic establishments round London, and I may say throughout the British dominions, are, generally speaking, utterly neglected in a curative point of view. Diet, drink, classification, exercise, and cleanliness, which are of the utmost importance, are regulated by no fixed and judicious principles tending to the cure of the disease. No means are taken to employ the mind, and thus call it back to a state of health, by relieving it from the distressing scenes passing around it; so that from this want of attention the malady almost invariably assumes a permanent and incurable form.

No language can pourtray the horror to which the individual, who is only partially deranged, must be subjected to under such an arrangement. In this miserable and forlorn condition are they left from month to month, from year to year, forsaken by their friends, so that they become, in many instances, from the want of affection on the part of their relatives, a kind of property to their superintendants, who are interested in keeping them, and often unjustly representing them as mad. It here gives us no small degree of pain to state that these evils, as it were, in a great measure flow from the present system of inspecting and licensing madhouses. The clean and unclean, the noisy, those insensible to the calls of nature, the epileptic, the individual partially deranged, and the convalescent, are all blended

together by day, and often by night, so that rest, so essential for the refection of the powers of the mind and of the body, is utterly unattainable. There are often three, four, and five, deranged persons made to sleep in a small apartment, and in this most unhappy condition are they kept from eight in the evening until eight next morning. The gentleman, who has been accustomed to the decencies of life, and to shift his linen daily, must find himself in a most lamentable condition under such discipline. Such scenes and such treatment reflect eternal disgrace on the relatives of the afflicted individual, who are able to afford a plan of treatment more liberal and more likely to conduce to his recovery. It is not the proprietors of mad-houses that are, in many instances, to blame; but we again state that the disgrace attaches to the relatives of the deranged, who withhold such allowances as are absolutely necessary for the re-establishment of the mental health of their afflicted friends; a vigilant and well-conducted system of inspection would obviate these disgraceful evils. A proper system of inspection extended to paupers would not only benefit these unfortunate individuals, by restoring many of them to health of mind, but it would conduce to economy to an extent of which the public are not aware. County asylums, we again state, would contribute greatly to the comfort and recovery of those labouring under mental derangement, provided they are erected on an efficient plan, and that a proper system of discipline is impressed on them when they are in a condition to receive patients. The kind-hearted and benevolent Lord Robert Seymour, who possesses a thorough knowledge of the existing evils in the management of the deranged, has laboured in favour of these unfortunate men with a degree of perseverance, humanity and industry, that reflects the highest degree of credit on his character, and such conduct associates his name with the benefactors of the human race. It is devoutly to be hoped that his views may be carried into effect, as they are founded in experience and careful examination, which have enabled him to point out the means of remedying those evils that have been adverted to, and the existence of which are a signal disgrace to those who unquestionably have had it in their power to correct them long before the present period.

DEMOCRITUS*.

*. Justly holding in extreme abhorrence all kidnappers and lunacy fanciers, whether in the form of judges, masters in Chancery, doctors, lawyers, or mad-house keepers.

**REFORMS IN THE COLLEGE OF
PHYSICIANS.**

WE are always delighted when we find anything in the opinions of our contemporaries to which we can assent, or anything in their conduct which we can commend. We have, accordingly, derived much gratification from the leading article in the Medical Gazette of last week, in which that journal fairly abjures a part at least of its former errors, and declares itself friendly to reform in the College of Physicians. Yes—the Journal which erewhile could detect no stain or blemish in this noble institution, has at length discovered that the guardians of its honour “have remained unmoved observers of the progress of society, and of the signs of the times;” the Journal which for years has villified the licentiates, and eschewed Edinburgh degrees, is now of opinion that all the members of the College ought to be placed on a footing of honourable equality. We heartily congratulate our contemporary on his conversion, and are not disposed, as some less benign persons might be, to brand him with dishonesty and tergiversation; on the contrary, we hold that when a man has been all his life wrong, a sudden change to rectitude of opinion and conduct is a highly laudable species of inconsistency. Our green brother is now in the right way, and our only solicitude respecting him is, lest he should be led too far by the first impulse of new and generous sentiment—lest he should grow destructive, and become a medical *sans culotte*.

Certain measures of reform are, it appears, actually in progress in the College. The following announcement in the pages of our contemporary may, in some sort, be considered as official.

“At present it would be premature to

speak confidently of the result, particularly after the experience of last year, but we shall probably not mislead our readers in stating our conviction, that the first great changes in the shape of medical reform may be expected to emanate from the College of Physicians, and we have great reason to hope that they will be very much in conformity with the suggestions which have at various times been made in the pages of this journal. We do not mean that any thing which we have written has influenced the parties*, but that our opinions have derived their weight simply from being found to correspond with those prevailing among the most intelligent members of the profession who have directed their attention to the subject. The improvements, which we greatly hope will have passed through their first stage before the present number of our journal is published, consist in establishing an educational curriculum, and in taking from the English graduate his admission to the Fellowship as a matter of course, and in removing from other graduates the ban of exclusion which has been so long put upon them. All who completed a certain course of study, and attained a certain age, would thus, in the first instance, be licentiates, and all, after a certain time, be equally eligible to the Fellowship."

The Gazette anticipates some difficulty in converting the existing licentiates into fellows; but expresses a hope "that a large and free admission into the fellowship will be made at the outset—say of all respectable men of ten years' standing in the College." It is added, however, that "the objections to admitting all the licentiates are great and insurmountable, some of them being men who, never having had any adequate education, ought not to have been licensed by the College at all." On this we have only to remark, that if the want of proper medical education be a valid reason for not letting some of the licentiates in, it is an equally valid one for turning some of the fellows out; since the education implied in the possession of a medical degree from Ox-

ford or Cambridge is in no respect superior to that testified by a degree from Aberdeen or St. Andrew's. If the College has been unprincipled enough to let loose unqualified men upon the public, it would be cruel indeed to allow this *now* to operate to the prejudice of individual members of the profession.

We further learn that the College has "at length opened its eyes to the absurdity of compelling students aspiring to the highest honours in medicine to leave the metropolis, where, more than in any other part of the kingdom, opportunities of studying to advantage exist." Hereupon our contemporary reminds the College that it has the power of licensing persons as *physicians* who have no *degree*; and remarks, that "being physicians would place its members in public estimation, on the same footing as Doctors in Medicine: a physician without a degree would at most be but a nine days' wonder."

But the plan to which the Gazette gives the preference, is that of investing the College of Physicians with the power of granting degrees.

Now, on the one hand we see no reason why the town should be frightened from its propriety with Doctor *Sangrados*, and on the other we see a number of reasons why the power of granting degrees should not be given to the College of Physicians *alone*. Why not entrust this power to such a board, as was recommended by many of the most eminent physicians and surgeons in this metropolis before the Parliamentary Committee. It might consist of the College of Physicians and six recognized Lecturers on the different branches of medical science, who ought to be chosen by ballot every year. It is obvious that no individuals are so competent for the office of examiners as those engaged in teaching, and such are the examiners at all universities.

The annual election of Professors, according to seniority, would preclude the possibility of monopoly in teaching,

* *Quære*—May not the parties have influenced our contemporary?

against which all the Lecturers examined before Parliament contended. But, in opposition to the College of Physicians alone conferring degrees, we maintain the total incapacity of that body, as at present constituted, though we admit that they would interfere the least with the business of teaching, which is no doubt a point in their favour. If the sentiments of the Parliamentary Committee, and of all the Lecturers who petitioned the Privy Council against granting a charter to the London University, be borne in mind, we think there is no chance of any one of our medical schools obtaining the power to grant degrees, and that a reformed College of Physicians is likely to be the chosen body.

The favouritism which at present prevails at the College in the election of censors, renders such a board altogether unfit and incompetent to examine for degrees. It often happens that the junior fellows are the censors—individuals who have received the worst medical education in the kingdom, and who have little if any practical experience. It would be altogether preposterous to allow these men to grant degrees; and the necessity of associating with them some more competent persons is abundantly obvious. The admission of the licentiates to the fellowship will without doubt be an improvement in the constitution of the College of Physicians; but we will not deny that we regard any improvements in the existing medical corporations merely as steps towards an ulterior object—the establishment of one faculty, to which reforms in the present separate institutions will inevitably tend, though their influence may not be immediate. Thus, if the licentiates be admitted into the College of Physicians, its counsels will be directed by more enlightened views of medical science—men, a large proportion of whom have been educated and have practised both as physicians and surgeons, will see the intolerable

absurdity of recognising any distinction between these branches. Again, if a representative system can be introduced into the College of Surgeons, the superior intelligence of the general practitioners will soon begin to influence its proceedings; men who are, in effect, both physicians and surgeons, will spare no exertion to rescue surgery from the degraded state in which its present insulation has placed it, and to re-unite it with physic. The result of all this will be, that the two corporations will enter into a voluntary coalition for the formation of one great national faculty, and the monkish ignorance of the twelfth century will at last be dispersed by the increasing light of science—leaving men to wonder that its shadow could have stretched forward through so many ages of advancing knowledge.

—o—

HOMŒOPATHY AT A DISCOUNT.

—

THE following dialogue may serve to give some idea of the opinion held in Paris of the homœopathic doctrine. It took place in the Académie de Médecine, at its sitting of the 27th January.

The Minister of Public Instruction announced to the Academy that the Homœopathic Society, recently formed at Paris, had petitioned the government for a licence by which its existence should be legalized. According to their project a dispensary would be immediately established, in which all the patients would be treated gratuitously according to the homœopathic mode, and on the accumulation of sufficient funds, a clinical hospital, for the purpose of teaching the doctrine and method alluded to, would be founded. As these projected establishments have particular reference to the public health, the minister requested to know from the Academy whether it would be advisable to grant the necessary powers; and remarked in conclusion, that “the question was not one of opinion alone on a point of science, but of medical police, which the government were anxious to have solved.”

To answer this, a committee composed of MM. Hussen, Remauldin, Gueneau de

Massy, Sherminier, Boulay, De Sens, and Sispane, was proposed. Upon which,

M. MAINGAULT demanded that the committee should be composed of an equal number of members who believed and of those who disbelieved homœopathy. (*Great laughter*).

M. DENEUX thought that M. Maingault should be called on to point out the believers to the academy. (*Laughter*).

M. ANDRAL PERE.—We have first to solve a preliminary question. I should wish to know whether a minister of public instruction can ask a learned society to frame a report on an absurdity. Did the rules allow it, I would move the order of the day on the minister's letter. At all events, I shall propose that the president or the secretary write directly to the minister, expressing freely what the academy thinks of the piece of trickery adorned with the name of homœopathic medicine; and I shall resist the appointment of any committee. (*Right, right*).

M. LONDE.—The secretary should be ordered to inform the minister that he is imposed upon, and that it would be degrading to the Academy to be engaged in the discussion of such quackery. You will see the advantage that will be taken of our present proceeding: to-morrow we shall see it published that the Academy is discussing the doctrine of homœopathy, and has framed a committee thereupon.

M. LEPELLETIER.—I think, on the contrary, that the formation of the committee is the surest means of annihilating homœopathy. Messieurs the homœopaths throw the gauntlet to us: we ought to accept it.

M. KERAUDREN.—It might be better if the Academy entered into communication with the societies in Germany. (*Great interruption*). In that country homœopathy has made the greatest progress. (*Interruption*).

M. MARC.—Such is not the case; homœopathy is a subject of the utmost contempt in Germany: so much so, that, speaking about it very lately with a celebrated Berlin professor*, he said, "There are only three homœopaths in Berlin; one is a knave, and two are ignoramuses." (*Laughter*).

M. BRESCHET.—Some months ago I was

in Germany, in company with nearly 600 medical men. Some one attempted to raise the question of homœopathy, but no one would hear of it.

M. RENAULDIN observed, that the Academy should, however, answer the minister; the more as he had taken the precaution to abstract the question of science, and only proposed it as one of medical police.

M. COMAC.—Were all the members that are opposed to homœopathy named, we should all be of the committee.

The names of MM. Andral *Pere et Fils*, and M. Adelon, were then added to those first proposed for a committee.

INFLUENZA AGAIN PREVALENT.

—

A CATARRH, signalized by head-ache, painful cough, great prostration of strength, and rheumatic pains of the limbs, is at present epidemic in London. It is of the same character as the influenza that prevailed in 1833, with somewhat greater development of true inflammatory symptoms.

Hospital Reports.

—

ST. GEORGE'S HOSPITAL.

Necrosis of the Femur—Operation.

FEB. 5th.—A man, of middle age, has been some months in the hospital, having been the subject of a chronic inflammation of the femur, which has terminated in necrosis. The lower part of the thigh was considerably swollen, and had two sinuses in it; one of which was in its lower and outer part, just anterior to the popliteal space. These sinuses discharged constantly more or less of an offensive sanious matter; and a portion of bone was felt denuded of periosteum, at their bottom, when examined with the probe. A week ago a consultation of the various surgeons was held upon the case, when the general opinion was in favour of an operation for the removal of the sequestrum, which, from the duration of the case, it was now thought would be found sufficiently loose; and it was then understood that it should be performed to-day.

Accordingly, at the usual hour, the patient was brought into the theatre, and Mr. Keate commenced the operation by making an incision, about four inches in length, along the outer part of the thigh, commencing below the middle, and terminating just above the external condyle. By this incision the integuments and large mass of the external vastus muscle were divided, and at the same

* M. Dieffenbach, we suspect.

time several muscular arterial branches, three or four, which were disposed to bleed profusely, but were at once tied. Mr Keate now proceeded to separate the muscle from the bone, in order to allow of space for the application of the trephine. This was now employed, and, after much labour, a piece of the external case of new bone was removed. Endeavours were now made to remove the dead bone with the forceps, elevator, and other instruments, but after much toil only a little fragment was extracted. The trephine was, therefore, re-applied, and, by the removal of a fresh segment of new bone, the opening enlarged. The attempts at the extraction of the sequestrum were now renewed, but without effect, and it was found necessary to have recourse again to the trephine, as well as to one of Hey's saws, before more than very small fragments could be removed. At last the labours of the operator were rewarded by the extraction of a large irregular mass of sequestrum. The parts were now dressed, and the patient removed to the ward.

From many circumstances in the case, sufficiently apparent, the operation was attended with peculiar difficulty, and occupied the entire energies of the surgeon for the space of nearly an hour.

—o—

WESTMINSTER HOSPITAL.

Gun-shot Wound—Ligature of the Carotid— Necrosis of the Inferior Maxilla—Operation.

SAMUEL BRINNIGAN, aged 20, a native of Glasgow, was admitted into Northumberland Ward, January 7th, as a patient of Mr. Guthrie. He was in the service of Donna Maria during the Portuguese war, as a private in the regiment of Scotch Fusileers, and received a severe wound of the neck and face in an engagement at a village near Oporto, on March the 4th, 1833. It appears that a musket ball entered the left side of the neck, dividing the common carotid artery, and, passing diagonally across the upper part of the neck, emerged at the right side of the cheek, fracturing the angle of the lower jaw in its course. The artery was tied by Mr. Staff-surgeon Alcock, from whom he has a certificate. The wound in the face, by which the ball emerged, quickly healed, after two or three bits of bone had been discharged with the matter. About two or three months after the receipt of the injury, matter began to form about the angle of the jaw and summit of the neck, which broke through the skin and left a fistulous opening, which continues to discharge a glairy kind of pus, and is surrounded by a lurid patch of erythematous inflammation. Another fistulous opening also formed about twelve

months afterwards, about two inches above the other, and over the ascending ramus of the lower jaw. These fistulae are evidently connected with dead bone below. A very small opening also exists in the mouth, close by the last molar tooth of the lower jaw, and which discharges a little matter into that cavity. The patient himself says, that he thinks the ball must have passed through the mouth, as ever since he received the injury he has noticed a trifling loss of command over the motions of the tongue, and, as a consequence, a little impediment in his speech. This, however, is most likely owing to an injury of the hypoglossal nerve. There is considerable tumefaction of the cheek and neck around the diseased bone, and there has been a good deal of pain in this situation. Though of a delicate habit, at the present period his general health is good.

Feb. 3rd. During the last few days there has evidently been an increased degree of swelling and discharge, and the patient complains of more pain. The matter discharged is highly offensive. Mr. Guthrie said that he should in a few days endeavour to remove the dead piece of bone. The patient complains of a sensation giving him the idea of matter being confined within the cheek, particularly upon the sinus being probed.

7th. To-day Mr. Guthrie proceeded to the operation. He commenced by making an incision through the skin, the extensively thickened subcutaneous cellular tissue, and the masseter muscle, beginning at the upper sinus, and extending it outwards and downwards to the lower one. The bone being thus exposed, Mr. Guthrie endeavoured, by means of a strong knife and an elevator, to remove the dead portion; but after several trials, he only succeeded in getting away a small portion about half an inch in length. His efforts were now directed against a loose portion of considerable size; after the application of considerable force with the elevator and forceps, it was brought away, and was found to consist of a portion of the ascending ramus, and the whole of the condyloid process. It was entirely denuded of cartilage and ligament as well as of periosteum; it was almost of a black colour throughout, and was evidently in a necrosed state. There was, however, no attempt at its restoration, in the way of the formation of new bone. The wound was then dressed in the ordinary manner in such cases, and the patient sent to bed.

8th. The patient is going on well, and says that he has less pain than before the operation. Mr. Guthrie was gratified to find that there was no paralysis of the muscles of expression, of which he was apprehensive, considering that it was not unlikely that a main portion of the portio-dura might have been divided in the operation.

Abscess after Acute Rheumatism.

James Child, aged 54. was admitted Feb. 3d. into Northumberland Ward, as a patient of Mr. Guthrie. He is a carpenter by trade, of a stout make and plethoric habit, but states that he has uniformly been of temperate habits, and that during the last sixteen or seventeen years he has been quite exempt from ill health, until about a month ago, when he had a severe attack of acute rheumatism, from which he has just recovered. He has some recollection of having noticed a rather uneasy sensation in the right thigh; but whether it was connected with the present abscess he cannot say, as it either entirely disappeared during the arthritic attack, or was masked by its symptoms. During the convalescence, however, a swelling has appeared about the middle of the right thigh, on its anterior surface, which was attended with redness, heat, and pain; but there has been no rigors nor perspirations. He has been attending as an out-patient during the last few days, and has had poultices applied; and at the present time there is an evidently elevated and superficial swelling, affording a distinct sense of fluctuation, and covered by a livid coloured skin. The tumour is surrounded by extensively thickened integuments and other structures, giving it the brawny feeling of carbuncles. There is no appetite, tongue is covered with a whitish fur, and during the last two or three days there has been diarrhoea. The countenance is of a dirty yellowish colour; pulse 100, small and feeble. Mr. Guthrie made a free incision through the livid integuments so as to open the abscess, which discharged a large quantity of purulent matter—viz. about ten or twelve ounces. A linseed poultice was ordered to be applied, and the patient to take the following mixture:—

R_x. Quinæ. sulph. gr. xvj;
 Acid sulph. dilut. 3 ij;
 Tinct. cinchonæ comp. 3 ij;
 Infus. gentian. comp. 3 vj M.

Capt. cochl. ij ter in die.

6th. Considerable thickening remains in the structures surrounding the abscess, which has discharged matter pretty freely since it was opened, but has now nearly ceased to do so; it is now dressed with pledgets of simple dressing and a roller. To-day the patient has pointed out a fresh tumour, situated in the inner side of the calf of the opposite leg, in which there is redness, and heat, and pain, having a peculiar formicating character. There have, however, been no rigors nor perspirations, although the patient's attention has been directed to this point. A poultice has been ordered to be applied. The tongue is not nearly so much turred as at last report, and the bowels are moderately open. The pulse is 84, moderately full and strong. He continues the mixture.

7th. General health is improved; suppuration has not perceptibly advanced in the calf.

8th. The abscess in the calf is advancing towards the surface; general health good.

9th. The same as at last report.

PROCEEDINGS AT THE COLLEGE OF
 PHYSICIANS.

—

To the Editor of the Original Medical and Surgical Journal.

SIR—The company at the College of Physicians was informed by the learned President, that "in consequence of the exceedingly irritable state of the stomach and liver of the late Duke of Gloucester, no food could be retained in the former organ, and that *therefore* the royal patient sank." It is to be hoped that the major part of the Baronet's audience was composed of the unlearned in physic; otherwise it is hard to say whether the ignorance or the impudence of the reader was uppermost when he put forward the above exquisite piece of pathological reasoning: the chain of consequences is about as clear as that in the lines—

"He does not affect to dissemble his love,
 And *therefore* he kicks him down stairs."

Had the Baronet attended somewhat more to living, and less to dead languages, he might possibly have given us some more *modern* explanation of the cause of the death of his patient. As it is, the idea of death from the want of food, in fever, is precisely the converse idea of the old women that frequent almost all sick chambers, and lay it down, that if the patient "would but eat" he would soon be better—*therefore*, if he dies, he dies from the want of food: the prognosis of these old women is invaluable.

I need not take up the space of your Journal by shewing how the irritable state of the royal patient's stomach was connected with the unfortunate termination of his sufferings. There are few practitioners, I trust, who have treated a bilious or gastro-enteric case, who could not give a better account than that on which I have animadverted. It is lamentable to hear such trash proceeding from the head of a learned body, and pitiable to think that an enlightened Prime Minister, and some hundreds of educated professional men should have been obliged to listen to it.

Your obedient servant,

JULIUS.

—o—

Foreign Medicine.

Rickets.

THIS disease is sometimes announced by a state of debility, before any visible deformity of the bony system. The children neither can nor will go on their feet: they cry and moan when raised from the recumbent posture: this is the first degree of the disease.

At a later period the respiration begins to be difficult: sometimes a periodical suffocating state comes on: the patients perspire a great deal, particularly about the head: at this point rachitism commences.

Rachitic children have a peculiar way of placing their legs when lying freely in bed. They keep them crossed and drawn up, so as to have the abdomen between the thighs. Their urine has an odour altogether peculiar—the odour of mice. Their tears and cries are also characteristic when the disease is somewhat advanced; and a practised ear may always discover the existence of the complaint by this sign alone. Such children are rarely thirsty, even when labouring under inflammatory fever, with or without local affection. The head is frequently enormous, besides the vices of formation it generally exhibits, and they are generally more intelligent than other children: watery head is exceedingly rare with them.

There are rachitic children who have, notwithstanding, every appearance of health: this is *rachitis florida*. They are for the most part of a scrophulous habit: in them the disease probably depends on an actual want of osseous matter. The treatment in this case is the same; but the prognosis is more favourable, and the little patients sometimes rapidly get well in the spring or summer.

Previous to undertaking the cure, all the accessory symptoms, as cough, diarrhoea, &c., must be removed: M. Goëlis then prescribes, and mostly with good effect, the following powder:—

Prepared powdered oyster-shells, $\frac{1}{2}$ an ounce.
Iron filings $\frac{1}{2}$ drachm.
White sugar 3 drachms.

Mix and give a pinch of it morning and evening.

Three times a week a bath of hay-seeds is to be had. For diet, the children are to take once or twice a-day an infusion of acorns with milk: beef-tea: no farinaceous food should be given. They should not be allowed to remain seated, or much carried on the arm; the recumbent position is the best: they should not, however, lay in feather-beds.

M. Goëlis says that it is wrong to suppose that the oxides of iron are better tolerated by the patient than the filings. Madder, even when used for a long time, has never with him produced the smallest benefit in the treatment of rachitism. The most disastrous complication of the disease is the whooping cough.—From "*A brief Account of the different Modes of Treatment used in the Hospital for Children at Vienna*," by Dr. Goëlis, physician of the establishment.

Chronic Tension of the Skin.

This disease (*cutis tensa chronica*), though by no means rare, is scarcely at all known. It is characterized by a peculiar shining red tension of the skin of the face, chiefly about

the mouth: or else of the palms of the hands, the soles of the feet, or the upper and inner parts of the thighs. Gradually the stretched parts become harder and wrinkled, the lips become covered with scabby crusts, which extend to the cheeks, and under these crusts an acid liquid is found, that corrodes the tissue beneath. Ulcerations of the thighs, about the genitals, the soles of the feet, and palms of the hands, also break out.

This disease is for the most part traceable to a syphilitic taint, and the treatment is quite in accordance with this theory; calomel is the only remedy, the specific. M. Goëlis prescribes it, in the dose of a quarter or third of a grain, according to age, twice a-day. For beverage he orders a decoction of heart's-ease in milk, and some he orders a bran bath.

The disease is however seldom removed without leaving its traces behind it: around the mouth particularly marks of it remain. Caries, or some other disease of the osseous system, not unfrequently follows upon it. In the milder cases it passes into *crusta lactea*.—*Ibid.*

Sanguineous Tumours of the Head.

M. Goëlis advises that these tumours, when met with in neophytes, should not be opened: he says that children frequently die in consequence of such an operation. These, as also subcutaneous lymphatic tumours and œdema of the scalp, he touches with nitrate of silver, to which he says they yield. In like manner he treats *navi materni* with lunar caustic, and eradicates them by producing suppurative inflammation.—*Ibid.*

Subcutaneous Lymphatic Tumours.

After using caustic to them, as in the last instance, if upon being open they are ill-looking, they should be sprinkled with a mixture of rhubarb and finely powdered charcoal, as is done in scrophulous ulcers.—*Ibid.*

DEATH OF BARON DUPUYTREN.

THE renowned surgeon-in-chief of the Hôtel Dieu expired on Sunday last, Feb. 8th, in the fifty-sixth year of his age, and in the possession of his faculties to the last moment. He was the author of several works on anatomy, physiology, pathology, surgery, gravel, and numerous other treatises. We were the first to render his admirable surgical lectures in our language. When he visited this country, he inspected all our great hospitals. On coming into the theatre of Guy's Hospital, Sir Astley Cooper turned to the large assemblage of students, and said, "Behold the first surgeon in the world."

M. Dupuytren gained the summit of fame by his ability and indefatigable industry.

His hour for visiting the Hôtel Dieu was 6 o'clock in the morning, and he remained until 10 o'clock. On arriving at that great hospital he put on an apron and pair of slippers, and then proceeded to examine every patient under his care with the greatest minuteness. He also dressed most of their ulcers. He had a roll, containing the names of the students, called over every morning, and if any one was absent three times, he ordered his name to be erased from the list. This was his plan when we attended his instructions. After having visited his patients, he repaired to the theatre, and delivered a clinical lecture on the most important cases under his care.

M. Dupuytren was profoundly learned in surgery. He was acquainted with the best works in English, German, and Italian, and quoted them in his lectures. His practice was most extensive for some years past, and he amassed a large fortune. He has bequeathed to the faculty of medicine 200,000 francs for the endowment of a professorship of pathological anatomy. The faculty are about to arrange in the New Hospital a museum of anatomy, which they propose to call Musée Dupuytren. He has bequeathed his body to MM. Broussais and Cruveilhier, who, with MM. Basnillaud, Delmas, and Marx, have performed the autopsy. The brain presented a great size. It weighed, after having been partly dried, 2lb. 14oz. In the right hemisphere traces of a former apoplexy were discovered. The heart was enlarged, and weighed 20 oz.; the usual weight is about 12 oz. The right cavity of the chest contained a quantity of serous fluid. The kidneys were softened and contained gravel. The body was interred at Pere la Chaise on the 11th inst.

MM. Sanson and Begin are deputed to prepare the eulogy, and M. Marx, his former pupil, is to edit his works.

—o—

CORRESPONDENTS.

- A Dublin Friend.*—We merely replied.
An Old Subscriber.—It interests very few.
Q. in the Corner.—Mr. Guthrie had nothing to do with it; but it happened in the school with which he is connected.
Scrutator.—Sir R. Peel is not cajolable. He effected more salutary reforms in the criminal law than any statesman in England. He will not listen to corporate proposals, for he well knows that medical reform is much more important to the public than to the medical profession. We entertain no doubt but he will be influenced by Mr. Warburton's bill.
A Bristol Friend.—Real medical Tories.
A Manchester Subscriber.—We have numerous friends at Manchester.
Z., of Liverpool; A General Practitioner, at Hull; C. D., of Nottingham; Galen, of Edinburgh; E., of Durham; Medicus, at Newcastle-upon-Tyne—Dr. Ryan's Lectures, and Translation of the Formulary of Hospitals, will appear regularly, if time permit.
Castigator.—A reptile beneath contempt.
The Portsmouth Cholera Gazette.—We have received fifty-four letters during the week, complaining that the Gazette is forwarded "free, gratis, for nothing," as a sealed double letter, to non-subscribers. The parties must be hard up, to adopt this proceeding. We advise our friends to send it back in the same shape, through the two-penny post.
A Reformer.—A physician of the London College, one of the "aliene homines," the "minus docti," has a right by the Act of Hen. VIII., which confirms the charter of the College, to practise surgery; and he may supply medicines, free of expense, without incurring the slightest danger of prosecution by the Company of Wholesale Druggists, who smuggled an act through Parliament, as the Apothecaries' Company.

ON

MEDICAL JURISPRUDENCE,

DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,

At the University of London; Session 1834-35.

LECTURE XVIII.

Disqualification for Military or Civil Service.

GENTLEMEN—The next subject to which I have to direct your attention, is *Disqualification for Military or Civil Service.*

Every situation in life which requires active powers, implies a capability of exertion in the individual; but in these occupations which may be regarded as of a public nature, and in which the duties must be fulfilled, not as suits the convenience of the persons performing them, but the demands of the community, it is of importance to ascertain the capacity of the person engaging to perform them. In military service especially, the nature of the duties requires the fitness of the recruit to be minutely investigated, and the power of the soldier to perform them narrowly watched. On this account the qualifications for military service refer both to the admission to the service, and the performance of the duties during continuance in it. In the English army every recruit is examined by the regimental surgeon before he is permitted to join his corps, or, as the term is, before he is finally approved. He is stripped naked, in order to ascertain that he has the free use of every joint and limb; the perfect use of the various organs of sense; that he is not ruptured; is free from scrophulous affections of the glands; has no sores nor marks of old ulcers on his legs, nor varicose veins, nor diseased enlargements of the joints. No man deformed in his limbs is considered fit for service. Out of 30,603 conscripts examined for service in the French infantry, 36.2 per cent. were found to be unfit for military duty, in consequence of being deformed or infirm. It is even requisite that the recruit should have good teeth, to enable him to bite off the end of the cartridge. Many deformities of a different

kind, such as the ankylosis of joints, paralysis, and nodosities, impeding the free motion of the limbs, are obviously such insurmountable obstacles to the performance of the active duties of a soldier, that it is scarcely necessary to advert to them. Pulmonary consumption, whether already it have produced vomicae, or even a tendency to their formation, renders the person equally unfit to undergo the fatigues of a military service; and, therefore, every recruit unsound in such particulars must be rejected. It is scarcely necessary also, to mention *vertigo* among the causes of rejection: a man, with a loaded musket on his shoulder, becoming giddy in the ranks, might fall down, and, entangling the trigger of his musket in some part of his dress might shoot his neighbour, or any one near him: and if this be true of *vertigo*, it is still more so as regards *epilepsy*. Insanity, imbecility, dumbness, and blindness, are also very obvious adequate causes why a man should not be enlisted. Some other diseases are equally proper causes of rejection: such, for example, as gravel, requiring frequent evacuation of the urinary bladder, habitual incontinence of faeces, and fistula in ano. The most complete tables of diseases which unfit for military service are to be found in the French *Code de la Conscription*; and a translation of them is contained in Dr. Beck's *Elements of Medical Jurisprudence*, to which I beg leave to refer you. Mr. Marshall says, that recruits should not be approved who weigh less than the medium weight, namely—

At 17 years of age .	116 lb 9 $\frac{3}{4}$ averdupois
18	127 9 $\frac{1}{2}$
20	132 7 $\frac{1}{2}$
25	138 12 $\frac{1}{2}$

The mean height of the British infantry soldier is 5 feet 7 inches.

Men are generally more anxious to get out of the army than they were to enter it: but it is often, especially in time of war, politically wise to retain them with diseases which would have prevented their enlistment; and much caution is requisite to distinguish between true and feigned diseases, as soldiers soon become adepts in simulat-

ng diseases, to escape the performance of duty.

In noticing some of the principal simulated diseases, I will not confine my remarks solely to those put on by military impostors. The knowledge of feigned diseases, and the mode of detecting them, will be found useful in every situation, either public or private, which can be filled by a medical man. Many curious instances are recorded in the writings of Mahon, Foderè, Dr. Hennen, and Mr. Copland Hutchinson: and an excellent article on the subject is found in the eighth part of the *Cyclopedia of Medicine*, by Drs. Scott, Forbes, and Marshall. (Dublin Hospital Report, vol. 4; and the *Medical Gazette*, vol. vii, p. 238). All feigned diseases may be divided into two classes—*external* and *internal*. The principal affections intended to be simulated, which may be comprehended under the first class, are *ulcers, deformities, tumours, paralysis* of some member, *ophthalmia, blindness, and deafness*; those under the second, are *fevers, epilepsy, catalepsy, convulsions, syncope; hemorrhages* of various kinds; *affections of the heart, of the kidneys and urinary organs, dropsy, parietes, pregnancy, and insanity*. I will endeavour to give you a brief account of the mode in which each of these affections is simulated, and the method of detecting the imposition.

Ulcers have been at all times a fertile source of imposition, both in the army with skulkers, and out of it with mendicants. Formerly the credulity and ignorance of the public was easily imposed upon. A young woman went to the King of France, says Pigray, an old French surgeon, to be touched for a cancer of the breast: an imposition was suspected, and Pigray discovered it to be a slice of spleen neatly fixed on the mamma. The formation of real ulcers, however, is more common; they are produced by various means—incisions are made in the fleshy part of the leg, and copper coins imbedded in them, which soon brings on inflammation and the ulcerative process. They are also produced by the application of the recent root of several of the species of *ranunculus*, particularly the flammore, which possesses great acrimony. In the years 1812 and 1813, the number of patients in the Hospital at Sheerness with sore legs was alarmingly great; the surgeon, Mr. Robertson, suspecting some fraud, employed spies, and discovered that these ulcers were caused by a process termed, in the flash language of the place, *Far-hunting*, which consisted in rubbing the sand, used for scouring the deck of the hospital ship, with the thumb upon the skin, until it was rubbed down nearly to the bone. Mr. Robertson having cured half-a-dozen convicted of this practice, had them flogged, and never again was troubled with a feigned ulcer in his hospital since. The diagnostic symptoms between ulcers of this kind and real ulcers, are the absence of any constitutional disease, the

deficient callosity of the edges of the sores, and the generally more superficial nature of the ulcer than is usually found in the real state of this disease. The simulated ulcer is easily cured, by simply bathing the part with luke-warm water, and covering it with some clean lint. Ulcers formed with mineral acids are very difficult to detect: and those also formed with lime and soap.

Beggars frequently pretend to be maimed and deformed, with the view of exciting more compassion; but this is easily detected on stripping the patient naked: although sometimes, from long-continued disuse, and the keeping the limb always in the same position, contractions take place, and the member appears more emaciated than its fellow. In simulated ulcers the deceptions can be detected by closely watching the presumed patients, and observing whether the diseased appearances subside or disappear, when the opportunities of employing the hurtful substances are taken away. If the ulcers heal readily when the patients are closely watched, and re-appear when they are allowed greater freedom, we may conclude that our suspicions of deception are well founded, and means may be taken to expose or to counteract it.

Tumours of different kinds are imitated by blowing air into the cellular tissue. Thus it is blown under the integuments of the head, to give the appearance of hydrocephalus. A fraud of this kind, practised by a mendicant, is mentioned by Sauvages; it was discovered by removing the patch which covered the hole, and prevented the air from passing out. Nothing can be more easily detected than a fraud of this description, by remarking the absence of all constitutional symptoms; and even in emphysema arising from wounds penetrating the chest and lungs, which this species of inflation most readily imitates, the symptoms are very distressing: the patient labours for breath, his countenance becomes livid, his senses are stupified, and unless speedy relief be obtained, he falls a victim to the disease. Foderè mentions that a woman succeeded, by this method of inflation, in producing a remarkably excellent representation of ascites; but the symptoms which accompany dropsy being absent, she was soon detected: indeed, in these inflations there is the mere existence of tumour, with a quiet state of the system.

One of the most common simulated diseases is palsy; and such is the extraordinary self-possession of some individuals, that burning wax, moxas and heated irons, have been applied, in order to discover the fraud, without the smallest retraction of the supposed paralytic member being produced. Foderè gives two cases of this kind. (See vol. ii, p. 473.) I have seen some cases, and also remarked the stoicism with which the impostors bore to be pumped upon, pricked with needles, and many other pain-

ful applications, without the smallest appearance of feeling, particularly when they had reported that the members, besides being devoid of motion, were also insensible. Mr. Hutchinson recommends in these cases, when the patients belong to the navy or the army, and suspicion falls upon them, that an anodyne draught should be administered, and under its operation, that the nostrils be tickled with a straw; if the paralysis be not simulated, the healthy member only will be raised to the irritated part; but, when fraud is intended, both arms are likely to be employed, by shifting the irritation from one nostril to the other. A still more effectual method of discovering the fraud, is to drop some melted wax upon the paralysed arm or leg, just as the person is dropping off to sleep, under the influence of the narcotic. An excellent method is, to give the pretended paralytic an electrical shock, when he does not expect it; this rarely fails to expose the fraud. Whatever means are adopted, they should be put in practice when they are not suspected, when the pretended paralytic is off his guard: his stoicism, however sturdy, is not proof against unexpected pain, when the mind is not directed to the feelings of the body.

Ophthalmia is frequently simulated by soldiers, who wish to be exempted from duty, or to obtain a discharge from the service, by applying corrosive sublimate, and other irritating matters to the organ, sufficient to cause a considerable degree of inflammatory action in the part. In a paper by Dr. John Vetch, contained in the 4th vol. of the *Edinburgh Medical Journal*, we are informed that this practice was carried to a very great height in the 28th regiment of foot, at the time when the Egyptian ophthalmia prevailed in the British army. The manner in which this feigned ophthalmia may be detected is, by remarking whether it appear in one or both eyes; and, as it is produced in one eye only, we shall find that the affected eye, in general, is the right eye; unless the individual be left-handed, when it is as invariably the left eye. The simulated ophthalmia arrives at its acmè in a few hours; the swelling is chiefly in the conjunctiva, whereas, in real ophthalmia, the palpebræ are also much affected. In the simulated disease, when the sight is lost, there is rarely much organic alteration. By attention to these symptoms, the simulated disease can be readily detected.

Blindness is frequently simulated, not only by soldiers, but by mendicants. This is not so easily detected as is generally supposed, because, as Richter has ascertained, in true amaurosis the iris is sometimes sensitive to the stimulus of light, and contracts: but if, on throwing the reflected rays of the sun, from a mirror, upon the eye of a person supposed to be feigning blindness, no contraction of the pupil takes place, we may

then conclude that the disease actually exists; and, if the contraction be sudden and considerable, there is also some reason for concluding that the blindness is feigned. Short-sightedness is one of the disqualifications in the enlistment of soldiers, and is frequently feigned when men are drawn for the militia. The plan adopted by the French in ascertaining the truth in this respect, in men who wish to avoid the conscription, is ingenious. From knowing that short-sighted persons can read, by means of concave glasses, when a printed paper is brought close to his eyes, they put such spectacles on the noses of those who declare themselves to be short-sighted, and desire them to read a paper held close to the eye; if they can do this, the defect is admitted, but not otherwise.

Deafness and *Dumbness* have been occasionally admirably simulated; and it is difficult to detect the simulation. It may be done, however, by a little address; by relating something of interest to another person, whilst you are feeling the pulse of the impostor, or suspected impostor; the change in the countenance of the individual, and the effect which a consciousness of this being detected, produces on the pulse, generally leads an acute observer to detect the deception; and, if he can thus ascertain that the individual hears, the idea that he is dumb must fall to the ground. The plan which the celebrated Abbe Siccard pursued to detect an impostor who pretended to be dumb, may also be adopted. The Abbe required the impostor to answer a number of queries in writing, and finding that he spelt many words, not according to their established orthography, but according to the sound, he correctly concluded that he could not have been born deaf and dumb, because he wrote as we *hear*, and not as we *see*. But this proof would be rendered nugatory by a well educated impostor. I recollect, when a boy, being accessory to the detection of an impudent beggar, who had long levied contributions upon the public, on the plea of dumbness. It was agreed that whilst his attention was fully occupied by a fellow student, by conversing with him on the fingers, I was suddenly to prick his leg with a large needle, fixed to the end of a stick. The effect was electric; on feeling the puncture, he suddenly started and exclaimed—"Good God! what is that?" The sequel may be imagined: the impostor was turned out of the house, and was obliged to leave the neighbourhood.

Strictures of the Urethra have been so well simulated, that a bougie could not pass into the bladder, until the attention was deeply engaged in conversation, and of course withdrawn from the part. Had the confession of the individual who simulated this disease not confirmed the suspicions of Mr. Hutchinson, who has recorded a case of this kind, I confess that I should have been scepti-

tical with regard to this. In instances of *spasm*, where there can be no fraud, we find that much advantage results from abstracting the attention of the patient from the affected part. The same gentleman mentions another very singular instance of the power of volition over muscles not usually under the control of the will. A man was impressed into the navy, from on board a merchant vessel; and, to avoid being detained in the king's service, stated that he was ruptured in both groins: that he had been overhauled, that is examined, a dozen times by the surgeons of different ships of war, and as frequently discharged, as unserviceable.

"There certainly," says Mr. Hutchinson, "was a swelling in each groin, very much resembling hernia, but the weather at this time being extremely hot, and the scrotum therefore very pendent and flaccid, my attention was particularly called to it, and, on examination, I found the scrotum to be an empty bag, and the testes, of their natural size, lodged in the groins. As soon as this discovery was made, the poor man, from being at length and so unexpectedly detected, became quite unnerved, and so agitated, that, upon re-examining the parts, the testes were found to have descended into their proper places in the scrotum. After commending the man for his ingenuity, and, in place of physic, administering to him a glass of grog, his spirits were rapidly restored; and, seeing no longer any chance of eluding the king's service, he displayed before us several remarkable feats of the power which he possessed over these organs. He pulled both testes from the bottom of the scrotum up to the external abdominal rings, with considerable force, and again dropped them into their places with incredible facility." He could elevate the testicles either singly or together, and drop them in the same manner.

This power of the will is not confined to the moving organs, but sometimes extends to the nervous system. Women have appeared to be in so deep a magnetic sopor, that they have borne melted wax to be dropped upon them without the least agitation of countenance, yet the whole has proved a deception.

But the most extraordinary instance of the extent of the power of the mind over the vital functions, is related by the celebrated Dr. Cheyne, in his *Treatise on Nervous Diseases*. It is the case of an English officer, a Colonel Townshend, who could stop the motion of his heart and arteries at pleasure; he could die or expire when he pleased, and again revive. The story is too long to be told; but it is well authenticated: those who cannot procure Dr. Cheyne's work, may read it in Dr. Elliotson's translation of Blumenbach's *Elements of Physiology*, in which it is quoted at length.

It is not easy to determine the object of

these deceptions in many instances. I might mention several cases recorded by authors, in which no motive could be traced; but I will notice one only, which came under my own care. A young lady, only 16 years of age, who was in good health, affected to be suddenly attacked with excruciating pains about the region of the bladder. Large doses of opium and other means were prescribed to relieve her, but with apparently temporary benefit only: the pains appearing to return with unabated violence three or four times a-week. At one time the urine was retained for twenty-four hours, until the bladder was prodigiously distended, and she submitted to have it drawn off by a catheter. These symptoms continued, with little variation, for nearly ten months, during which time she had been seen, in consultation with me, by three of the most eminent physicians in London. During this period, my suspicions were several times raised, but they were almost as quickly suppressed, by reflecting on the respectability of the patient, and the absence of any motive for deception. At length I was sent for, late at night, and was seriously informed that my patient had discovered the cause of all her sufferings, and would now get well; for she had that night passed two stones from the bladder of urine. These stones, however, which were put into my hand, were never formed in the human body, but were small pebble stones, picked up from a gravel walk. She had no return of the pains, and was soon afterwards married. No motive could be assigned for this continued system of deception, except the desire of exciting commiseration, and being made the subject of conversation. When she ceased the practice, another and more exciting feeling, *love*, had taken possession of her mind; she became indifferent about *pity*: but it was necessary to terminate the apparent suffering under which she had so long laboured, by something which, in her opinion, would fully explain her hitherto inexplicable disease. She adopted the means which I have mentioned, and, whilst making water, dropped the stones into the chamber-pot, in the presence of her mother, who was as much the dupe of her deceit as the physicians had previously been. There is great difficulty in detecting frauds of this description; for, although a practitioner of observation remarks the distinction between the symptoms presented to him and those of real disease, yet, not suspecting fraud, he endeavours to account for the anomalous appearances; and, although still puzzled, he continues to treat them as cases of actual disease. If the medicines which he prescribes are taken by the patient, he traces their usual operation upon the body, but is disappointed in his hope of their relieving or removing the symptoms by the medicines to which they have generally yielded when no particular idiosyncrasy has existed to op-

pose their operation. The profession is brought into disrepute by the apparently repeated failures; and the practitioner, if a young man, is not only deeply injured in character, but he begins to lose his confidence in medicine, and, consequently, to abate his ardour for inquiry, and to relax his attention in observing the influence of remedies, and gradually sinks into the state of a mere routine prescriber. But a more serious evil springs from these deceptions, when the object of the individual practising them being attained, the patients appear to owe their recovery to certain plans of treatment which are of a novel character, or to the employment of a new remedy. In these instances, the plan of treatment or the new remedy is published to the world, and others are misled by the representations, to perhaps the irreparable injury of unfortunate patients. I will illustrate this remark by a case which came under my own care, and was published eight years since, in a work which has been extensively read, besides being noticed in several journals.

The patient was a young lady, under fifteen years of age, of a sanguine temperament and quick parts, but not fond of study, and impatient under restraint of any kind. She stated, that a year before the time at which I saw her, she suffered under an attack of tic douloureux, for which Dr. Baillie attended her. It was less severe than her present attack, but sufficient to oblige her to be removed from school. She described the pain, the seat of which was about an inch backward from the symphysis of the lower jaw, and apparently in the course of the branch of the ninth pair of nerves which supplies the genio-hyoideus muscle. She described the throat as being also partially affected, and stated that deglutition was somewhat impeded, as well as speech disturbed. The screams of the patient, when the paroxysm returned, and the writhings indicative of the torture caused by the pain, were most heart-rending to those who witnessed them.

Finding that every remedy with which I was acquainted had previously failed in the hands of Dr. Baillie, I resolved to try the effect of a powerful mental impression; and, with this in view, I made inquiry of the lady under whose charge the patient was at school, whether she knew of any strong antipathies of her pupil. She stated that she had an unconquerable dislike to a dog who was in the house; and, having obtained this information, I proceeded to the room of the patient, and informed her, with as much gravity of countenance as I could command, that the only other remedy which I had in store for her disease, all others having failed, was to have the affected part rubbed with the back of the dog, and that I meant instantly to have it applied. Whilst I was stating my intention, she became as pallid as a corpse, large drops of sweat formed on her

forehead, and she appeared passing into the most alarming syncope. From that moment no other attack of tic occurred until eighteen months afterwards, when the disease recurred in the same apparent degree and manner as before; but it was immediately arrested by suddenly taking the patient out of bed, and hurrying her into a shower bath. Now, at the time when the cure in both instances was published, it was attributed to the powerful impression made upon the nervous system through the mind; but, to shew the fallacy into which a physician may be led in reasoning upon the apparent effects of medicines, I have only to mention, that, eight years afterwards, I received a letter from the patient, who was at this time married, and the mother of two children, acknowledging that the whole of the attacks under which she was supposed to labour, when at school, were feigned, with no other view than to get from school*.

Internal diseases are simulated in two ways:—1. a temporary diseased state of the body may be produced by substances of various kinds taken into the stomach, or applied to the surface of the body: 2. appearances very similar to the symptoms of diseases may be altogether the effect of imitation. Both modes are not unfrequent; but the first method is chiefly practised by soldiers and sailors.

Fevers are simulated by swallowing a mixture of soap and tobacco, which produces a small rapid pulse closely resembling that of continued fever, with a brown fur on the tongue. The same state, Foderé says, can be produced by smoking cummin seeds; and Dr. Paris informs us, that a paroxysm of fever may be excited and kept up by the introduction of a clove of garlic into the rectum. But these deceptions are readily detected by confining the person to bed, and closely watching him; the symptoms, instead of increasing, as in real fever, entirely disappear in a few hours. It is not more difficult to detect the simulation of ague by old soldiers, who, Dr. Hennen informs us, are deeply versed in the history of a paroxysm of intermittent, and very skilful in imitating the rigors, and giving the febrile aspect of the tongue, by whitening it with chalk. The absence of the hot and sweating stages of the paroxysm readily discover these imitations.

Epilepsy being a disease which recurs only at intervals, and which can be readily assumed at the moment most convenient for the object of an impostor, has been more frequently and successfully simulated than most other general diseases. To give the appearance of bloody froth, which frequently issues from the mouth in real epileptic fits, in which the tongue is often wounded, blood is sucked from the gums and soap chewed,

* The lecturer here read the letter—merely withholding the name of the lady,

The best means of detecting this imposition is to wait until the sleep, which is the usual termination of the paroxysm, be imitated, and then either to drop hot sealing wax, or to apply a red hot iron to the leg of the impostor; the true epileptic is insensible to pain at this time; but it is rarely that the impostor does not display sensation on being thus tried. It is of no use to apply such means during the pretended convulsions, as during the compression of the nervous filaments, by the voluntary violent contractions of the muscles, sensibility is so much reduced that pins and needles may be run into the body, and the most irritating applications made to it, without the individuals betraying the least consciousness. A more satisfactory method of detecting the deceit is to ascertain the contractility of the pupil, which does not take place in real epilepsy, and also to observe whether the face become livid. Another method is the application of sternutatories to the nostrils, which have no influence in real epilepsy, but produce sneezing in the feigned disease. De Haen relates the case of a girl who was brought to the hospital at Vienna with epilepsy, which, from occurring once or twice a day, now occurred every hour. The resemblance was good in every respect but one; during the paroxysm she did not open her eyes with a winking, but in the natural way, which, along with the natural state of the pulse, and the contractility of the pupil to light, led De Haen to suspect some deceit. He ordered her to be taken out of bed, and directed the attendants, in her hearing, to place her erect, and, if she fell, to chastise her severely. She took care not to fall, and by this display of volition the fraud was detected. An excellent method of detecting the feigned disease in a beggar was practised at Paris. This man had excited so much compassion, that a bed of straw was prepared, on which he might fall without injury to himself: at length, the fraud being suspected, the four corners of the bed of straw were set on fire, whilst he lay on it in a paroxysm of the disease. He quickly sprang up, and fled.

Dr. Beck justly remarks, that "one fact should be kept in view respecting this disease. The real epileptic is desirous of concealing his situation, and attaches to it a kind of false shame, while those who feign the disease talk about it, and take no precaution to avoid publicity.

Catalepsy is a disease of very rare occurrence, but is, nevertheless, occasionally feigned. The real disease consists in an instantaneous rigidity of the trunk and limbs, the suspension of the senses, and temporary interruption of the exercise of the intellectual faculties. The posture and expression of countenance at the moment of seizure is retained by the patient, and from its not varying, and the fixed attitude of the body, the person appears actually like a

statue. The pupil contracts on the approach of light, but the eyelids continue fixed, and the balance of power between the flexor and extensor muscles is so equal, that any new position in which the limbs or trunk of the body is placed by force, is maintained. The return to the natural state is as instantaneous as the attack of the disease. It is generally the result of sudden and powerful shocks to the nervous system; and the symptoms are so singular that Dr. Cullen and several other medical writers have considered it as in every instance a feigned disease. I have seen two cases of it, in one of which no doubt could be entertained of the reality of the disease; and, in the other, no motive existed for deception. I will describe to you the most interesting and undoubted of these cases. I was attending, nearly twenty years ago, an officer in the army, who was labouring under phthisis, in the last stage of the disease. His hope of recovery was still, however, kept alive in his mind and that of his wife, so that his friends could not persuade him either to make his will or to sell his commission, which was all that he had to bequeath to his wife and an only daughter. At length he became sensible of his danger, and drew up a petition to the commander in chief, for leave to sell out; and at the same time he made his will. I was sent for to witness his signature to both. Having executed these deeds, his mind seemed much relieved, and I left him more happy than he had been for many months. I had not, however, left the house five minutes before the servant ran breathless after me, and required my immediate presence, as her master was much worse. I returned instantly, but my patient was dead: he had fallen back on the bed immediately I left the house, and expired without a groan. His poor wife was standing by the side of the bed like a statue; pale, her eye fixed, as it were, on vacancy, and insensible evidently to my entrance into the room. Finding that her poor husband was past all human aid, I approached Mrs. —; she seemed to take no notice of anything; I took her hand—she felt it not; I spoke to her—my voice was unheard; no pulse was perceptible at the wrist; and it was only by the dew on a mirror approached to her mouth that I was satisfied that she breathed. It instantly occurred to me that it was an attack of catalepsy; and I was confirmed in my opinion by finding that the arms and other parts of the body remained fixed in any position in which they were placed. She was put to bed, and continued in this state for forty-two hours; after which she suddenly seemed, as it were, to awake, was sick, and re-action soon came out, and augmented to fever. She was two months ill, and in a most precarious condition.

This case is a parallel to one described by the late Dr. Good, which I will take the liberty of reading to you. (The lecturer

read the passage from Good's Study of Med. vol. iii, p. 578.) I will also notice another remarkable case quoted by Sir Alex. Crichton from the fifth vol. of the Psychological Mag., and quoted in his work on Insanity. (The case was read.) These statements are sufficient to convince you, I hope, that catalepsy is a real disease; and, from its nature, it might be thought one unlikely to be imitated; but this has been attempted several times, with variable success. Dr. Hennen mentions an instance of it in a soldier, in the royal African corps, of the name of Drake, who assumed an appearance of total insensibility, and resisted every kind of severe treatment for some months, even the shower bath and electricity; but on a proposal being uttered in his hearing, to apply a red hot iron, his pulse rose; and when preparations were made, and the hot iron was approached to his body, he displayed sufficient signs of sensibility: on proposing to send him to Bethlem hospital, he gradually recovered. Another case is recorded of a young soldier, who resisted measures of still greater severity; he permitted pins to be thrust under his nails; his head to be trephined; and several other cruel acts committed; yet persisted in the deception until he procured his discharge; immediately after which he was seen in perfect health, employed actively in his father's house. The following curious method of detection was employed by John Hunter:—The patient was a young man, a patient of St. George's Hospital; he apparently lost every power of volition and consciousness, and remained in the attitude in which he was placed. John Hunter commented on the case to the students surrounding him, whilst the man stood near, with his arm extended and a little elevated—"You see, Gentlemen," said Mr. Hunter, "that the

hand is supported merely in consequence of the muscles persevering in that action to which volition had excited them prior to the cataleptic seizure. I wonder," continued he, "what additional weight they would support;" and, so saying, he slipped the noose of a cord round the wrist, and hung to the other end a small weight, which produced no alteration in the position of the hand. Then, after a short time, with a pair of scissors, he imperceptibly snipped the cord; the weight fell to the ground, and the hand was as suddenly raised in the air, by the increased effort which volition had excited for the support of the increased weight, and at once unveiling the imposture, as the possession of both consciousness and volition was thus demonstrated. It might be supposed that such deceptions as this would readily be recognized by the state of the pulse; but the power of the will over even the function of the heart, which some persons possess, is truly wonderful. In proof of this, it is merely necessary to refer to the case of Colonel Townsend, related by Dr. Cheyne on Nervous Diseases, p. 307*.

This extraordinary case may be regarded as an example of the power which may be exerted, of feigning *syncope*; and another similar instance used to be noticed by D. Cleghorn, of Glasgow, in his lectures; in which the individual had so completely the power of arresting the action of the heart, that he could render the pulse imperceptible at the wrist, whenever he pleased; and thus feigned death without any difficulty.

At our next meeting I shall conclude this subject.

* See Elliotson's Blumenbach, p. 266.

LECTURES ON THE INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF
MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE XI.

Applications of Organic Chemistry to Physiology.

In the remarks which have preceded, it has been throughout presumed that, however distinct may be the chemical nature of the several Organized Tissues, and that of the Unorganized Tissues and Fluids, all the vegetable and animal compounds, above enumerated as proximate principles, are the results of the associations of certain elements effected by secretion, as a process, although not identical with, still analogous to common chemical affinity; but it would be improper to dismiss the subject without remarking that it is by no means certain, on the one hand, that these alleged elements are really so, or, on the other, that secretion is not a process essentially different from common chemical affinity, as well in the *material* as in the manner of its operation. The avenues by which all the oxygen and hydrogen, which these compounds contain, enter the organized system are

supposed to be sufficiently obvious; but, with respect to the carbon, it has been proved by ample experiments that plants and animals in general excrete constantly from their respiratory organs alone—to say nothing of its consumption in other ways—much more of this principle than has any evident ingress into the system (*a*); and the source of such an abundance of nitrogen as many plants and all animals, herbivorous as well as carnivorous, contain, is a subject involved in much obscurity. It is known to be abundantly evolved from some of the Fungi and Cruciferae, as the mushroom and mustard, when nourished by apparently perfectly pure water (*b*); it exists in zoophytes, which remain permanently attached to rocks at the bottom of the sea; and it has been found that fishes (*c*), which, of all animals, most abound in this principle, and in the air-bladders of some of which it is found almost pure, as well as some reptiles (*d*) live and grow though kept for years in water alone. Again, plants which grow in sand, or upon granite, are found to contain as much lime—the chief element of which is calcium—as those which grow in a calcarous soil (*e*); the bones of the native animals of some districts of New South Wales, in which not a particle of lime, it is said, is to be detected in either the soil or the vegetable productions, contain this substance, in the state of phosphate of lime, in the usual quantities; and the same has been found excreted, in the state of carbonate, with the egg-shells of hens, in quantities for which the food taken is quite inadequate to account (*f*): the enormous masses also of carbonate of lime sometimes laid down in the form of coral-rocks, &c., by minute animals, without any manifest supply of its ingredients, are sufficiently well known. Similar to these anomalies is that of the abundant excretion of sodium, in the form of carbonate of soda, by plants—the *Salsola Soda*, for example—when growing in a soil which does not contain an atom of it (*g*); as well as that of the occasional presence, it is said, of copper in some shell-fish, and of gold in the bezoards, or intestinal concretions of certain herbivorous quadrupeds, the sources of both which are equally obscure. It is true that attempts have been made to explain, on ordinary principles, the evolution by plants of the great quantity of carbon above alluded to (*h*), as well as that of the nitrogen (*i*), of the calcium (*k*), and of the sodium (*l*); and similar attempts have been made to account for the appearance of some of those elements in animal compounds, the source of which is equally ambiguous—in particular of the nitrogen, which has been confidently traced, as well in herbivorous as in carnivorous animals, to the food on which they subsist (*m*). Of most of these attempts, however, it is sufficient to say that they are by no means satisfactory; and that the source of many of the presumed elements in the reputed proximate principles of both plants and animals is still very problematical.

May we not then hazard a conjecture that these presumed elements, or at least many of them, are not really elementary, but composed of ulterior atoms, for which we have no names, but which, united together in various proportions, constitute the substances in question? We call the latter elements only because we are incapable of either decomposing or composing them in a common chemical laboratory (*n*); but it is not certain that

(*a*) That plants evolve, in this way, more carbon than can be satisfactorily accounted for, was proved long ago by Dr. Crell; and, with respect to animals, of the forty-three ounces of carbonic acid lately mentioned as voided day by day from the lungs of man, nearly twelve ounces are pure carbon, the only obvious source of which is the aliment. Now, admitting that of the hundred ounces of aliment received in this period, at least ninety are nothing but oxygen and hydrogen in the form of water—which constitutes so large a proportion, as well of our solid as of our liquid food—ten ounces only are left to furnish, with much more oxygen and hydrogen, all the carbon and nitrogen of the system.

(*h*) Saussure, Goëppert, &c.,

(*i*) Kirwan, &c.

(*k*) Bergmann, &c.

(*l*) Saussure, Davy, &c.

(*m*) This conclusion has been drawn by Magendie, who found that animals soon died when fed exclusively on pure gum, sugar, oil, or any other substance quite destitute of nitrogen, with distilled water. The result, however, of the unfortunate experiments made many years ago upon himself, by Stark, of Vienna, sufficiently displays the inadequacy of any kind of aliment, if too long persevered in, to support the vital powers; and it has been well shewn by Dr. Paris that highly concentrated aliment is very ill adapted to this end, as not affording a sufficient stimulus to the digestive organs, and that it was not for lack of nitrogen, but for lack of food—abundant and, abstractedly considered, nutritious as their food was—that the subjects of the experiments of Magendie perished. The most highly azotized aliment, under the same circumstances of want of change and excessive concentration, would have had precisely the same effect.

(*n*) "The number of substances admitted as elementary," says Sir Charles Morgan, "is liable to perpetual variations; for, the

the powers brought into operation in the laboratory of the organized body—the powers of secretion—cannot first decompose, say oxygen or hydrogen, into certain ulterior atoms, and afterwards re-combine some of the latter into carbon, or nitrogen, or other reputedly elementary substances, the source of which has just been represented as so mysterious. However this may be, we seem at least justified in concluding, not only that the immediate chemical nature of organized matter is very different from that of such as is unorganized: but also that its alleged elements are somewhat questionable, that the process of secretion—by which the ultimate ingredients of all vegetable and animal compounds, whatever they may be, are associated together—is an infinitely more subtle and searching power than that of common chemical affinity, and that there exists between the two, perhaps only a very faint and remote analogy.

Taking then all these circumstances into consideration, we need be at no loss to account for the very little advancement which either physiology, pathology, or therapeutics, have hitherto derived from the study of organic chemistry—an advancement certainly very disproportionate to the expectations which were at one time entertained of it, and to the ardour with which it has been so long prosecuted (*a*). We indeed tacitly acknowledge that the composition of an organized being, whether in health or in disease, is out of the pale of common chemical doctrines, by in general, instinctively, as it were, abandoning such doctrines, whenever we come to speak of the proper business of these sciences. Is there any thing, for example, in the history of the properties of osmazom, of sodo-albumen, of gelatin, or of fibrin—pompously and circumstantially as these are sometimes set forth, under a vague impression of their importance—which assists us one jot in explaining any one of the physiological properties of a membrane, a nerve, or a muscle? Is it from any change in their reputed proximate principles that membranes contract adhesions, nerves become softened, and muscles indurated? or do we seek to remove the first by dissolving their sodo-albumen or gelatin, to harden the second by coagulating their osmazom or sodo-albumen, or to soften the last by acting in any way on their osmazom, sodo-albumen, gelatin, or fibrin? The idea is palpably absurd. We *feel* that organized tissues, whether sound or diseased, are not amenable to common chemical laws, nor within the reach of common chemical agents, as having, in fact, none of these so called proximate principles in their composition; nor has the application of organic chemistry to the unorganized tissues and fluids, as connected with certain conditions of the organized parts, been hitherto so happy, as at all to invalidate the conclusion above adopted. We know indeed that the chemical character of the mucilage, for example, of the bile, of the stools, of the urine, and of several other secreted fluids, is variously affected in numerous diseases, and we have established about four distinct kinds of biliary concretions, double that number of intestinal, and almost double that number again of urinary; but what real light, it may be asked, has the knowledge of these facts thrown either on the processes by which such matters are produced, or on the means by which such processes may be counteracted or subverted? On the other hand, most of the hypotheses—when such have been broached—whether physiological, pathological, or therapeutical, which rest on a chemical foundation, involving either the supposed proximate, or the supposed ultimate principles of the body, have been eminently unfortunate. Witness the hypothesis lately alluded to, that the contractions of muscles depend on the coagulation of their supposed fibrin; and that, still more absurd, which assumes that these contractions are effected directly by the motions of the fibrin of muscles already coagulated, and represents accordingly the crassamentum of the blood as susceptible of the same, on the application of a stimulus (*b*). How vaguely, again, has diabetes been ascribed to the presence of ready-made sugar in the blood (*c*), and scrofula, or a tendency to deposit tubercular matter in various parts of the body, to a superabundance in it of sodo-albumen (*d*), and abstinence, therefore, from the white of eggs, in this disease, gravely inculcated (*e*). How idly has

epithet referring to one's own powers of operation, and not to qualities inherent in the subject, it becomes applicable or otherwise, as the species in question is affected by the progress of chemical research. The term element must not therefore be taken as conveying a positive assertion respecting the intimate nature of the body to which it applies. It does not signify undecomposable, but undecomposed."—(On the Philosophy of Life, 1818, p. 29.)

(*a*) It was long ago perceived by Sprengel that organic chemistry could never afford any principles of physiology; and it was

sagaciously remarked by one of our best medical journalists, soon after it began to be fashionable to apply this study to physiology and pathology, "We are not even certain that we are in the right path, and that we shall not be obliged to retrace our steps." *Edinburgh Medical and Surgical Journal*, 1816. How prophetic was this observation!

(*b*) Tourdes and Circaud, contradicted by Heidmann, *Reil's Archiv*. VI., S. 417, &c.

(*c*) Dobson and Rollo, contradicted by Wollaston, Marcet, Thenard, and Vauquelin.

(*d*) Dr. Parr, *Medical Dictionary*, 1809.

(*e*) M. Ségalas goes even further than th

it been attempted to establish a connection between the liability to croup, with the consequent formation of a morbid membrane in the trachea, and the quantity of fibrin in the blood (a)—and seriously recommended to try to obviate this effect by copious dilution (b)—nay, how incorrectly do we almost constantly speak of the rudiments of any new growth, as merely coagulable lymph, or fibrin, *effused* by the arteries, and organized, as it were, mechanically (c), instead of a proper germ or matter, *secreted* by these vessels, and containing within itself the rudiments of its own organism. All this, however, is quite of a piece with the conceit so long entertained, and still by some persons so fondly clung to, that numerous diseases, such as scrofula (d), urinary calculi of uric acid (e), gout (f), and rickets (g), have their origin in too acid a state of the blood; while others, on the contrary, as diabetes (h), urinary calculi of the phosphates (i), exostoses (k), and sea-scurvy (l), arise from too alkaline a state of this fluid; and hence the alleged reason that acid substances are injurious, and alkaline beneficial, in the former diseases, while the reverse is the case in the latter. Again, either an alkaline or some other morbid condition of the blood, has been presumed to prevail also in most of the diseases of the skin (m), and in all the so-called putrid diseases (n), and to be the cause of all the peculiarities which they severally display. Nor is it only with respect to the supposed proximate principles of the blood—which has been thus ingeniously inferred to be saccharine, or too albuminous or fibrinous, when the secreting vessels have formed from it *de novo* compounds, which are found to contain these matters, or too acid or alkaline, when these vessels have deposited in the same manner a calculus, or a gouty concretion unfortunately containing an acid, or

and condemns cow's milk in scrophula, not only because it contains albumen, but because cows, as shown by M. Huzard, are very liable to tubercular accretions! By what process, or series of processes, these are to pass *en masse* out of the body of the cow with her milk, and again into the body of the drinker thereof, does not immediately appear: but, granting that the secreting vessels are thus easily influenced with respect to the nature of the organized matters which they deposit, we need be at no loss, at any time, for a new pleura or peritoneum, a new nervous system, or a new set of muscles, as occasion may require, since, without trying to manufacture them in a laboratory, as some persons have presumed that we shall in no long time be competent to do, they may easily be got by feeding on isinglass or carpenter's glue, on the white of eggs, or on the clot of the blood of bulls or of goats. M. Bonhomme's suggestion of taking crude phosphate of lime in rickets, for the purpose of setting new bones, was a mere bagatelle to what may be done in this way.

(a) Dr. Mason Good, Study of Medicine, 1822, the early fellow-labourer of Dr. Parr, has the credit of having first directed "the prying eye of philosophy" into this promising field.

(b) Piorry.

(c) See Home and Bauer's ingenious suggestions respecting the squirting out of carbonic acid from the reputed fibrin, at the instant of its supposed coagulation, leaving channels into which the blood from the contiguous parts was squirted in, and thus the organization was effected. Phil Trans. 1818 and 1820.

(d) This doctrine is as old as the times of Arabian physicians, who were the first to substitute a supposed vitiation of the humours as the cause of diseases in general for the supposed loss of balance in their distribution, as maintained by the first humoral

pathologists.

(e) Wollaston, Magendie, &c.

(f) Mazuyer, &c. The "specificité" *à toto* of gout has been denied by the Broussaists, and lately by Dr. Leese; but we may admit the "specificité" of the inflammation without attributing it to the cause above alluded to.

(g) The notion that rickets arose from this cause originated in an absurd hypothesis invented by the chemists, to explain ossification, which they chose to represent as quite analogous to petrification, or the deposition of tufa, the matter being first deposited by a fluid in the state of a soluble super-salt, and afterwards reduced to that of an insoluble neutral salt by the removal of its superfluous acid. This, in the former case, was of course to be effected by the absorbent vessels; but these, if already overcharged with acid, refused to do so, and hence the earth of bones was left in a soluble state. The blood in rickets was accordingly found by M. Vienac to effervesce in a wonderful manner with the carbonates of alkalies!

(h) That diabetes depends on too little phosphoric acid in the blood is the conclusion to which Dr. Latham arrived after several years spent, as he expresses it, "in weaving hypotheses" to explain this disease; his success is certainly as remarkable as his assiduity was exemplary.

(i & k) These two diseases are directly opposed to rickets upon the principles above stated; while their immediate cause is the same as that of diabetes, as might indeed have been anticipated from the great similarity of the symptoms.

(l) This idea respecting sea-scurvy has been prevalent from the earliest writers on the disease down to the time of Cullen. It has been shown to be false by Deyeux and Parmentier, by Lind and by Parry.

(m & n) Lorty, Cullen, Mason, Good, &c.

matters of which the ingredients either are, or are supposed to be, too alkaline—that such doctrines have been adventured; but a loss of balance in the presumed elements of the organized body has been frequently, and in general equally unhappily, put in requisition to explain various diseases: and, in the first place, in whatever way these elements may be conceived to enter the animal body, it has been very generally inculcated that to the subsequent expulsion of each, except the oxygen, which goes off indiscriminately by every avenue, a specific organ is appropriated, the hydrogen, for example, escaping with the bile from the liver, the carbon with the carbonic acid from the lungs, the nitrogen with urine from the kidneys, and so forth (*a*); consequently, when any one of these organs performs less or more than its assigned part—to say nothing of the probability that more or less of these principles may at the same time be taken in—there must arise either an abundance or a deficiency of some one of them, and from each in either case its own train of diseases. Moreover, males, it is said, under ordinary circumstances, always abound more in oxygen, and females in hydrogen, so that the embryo derives almost the whole of the former principle from its father, and almost the whole of the latter from its mother (*b*); but from each of them thus in excess in the respective sexes certain liabilities to disease will of course arise. Thus, a superfluity of oxygen has been confidently represented as giving rise to phthisis, as a deficiency of it has to sea-scurvy (*c*); and it is on these grounds that the inhalation of hydrogenous gases in the former, and the employment of acids and ascescent fruits and salads, as containing oxygen, in the latter have been supposed to be beneficial. On the other hand, an excess of hydrogen produced by dram-drinking has been supposed to give rise to catacansis or spontaneous combustion (*d*); and an excess of carbon, occasioned by the undue admixture of venous with arterial blood, to give rise to all the bad symptoms of cyania or morbus cæruleus—whether, on the one hand, any diseases arise from a deficiency of either of these principles is uncertain.

Again, it has been imagined that it is from a superabundance of nitrogen that urinary calculi of uric acid and gout take their rise—the uric acid unfortunately containing nitrogen as one of its ingredients—and it is on this account it is supposed that, besides the use of alcalies, vegetable food agrees but with persons troubled with these diseases; whereas it is from too little nitrogen, on the contrary, that diabetes has been conceived to arise (*e*), and hence the advantage experienced from exclusively animal food in this disorder. But it is not only these chief elements which either in excess or deficiency may be, it has been supposed, at the bottom of so many diseases, but others of less importance, as sulphur, arsenic, &c., when superabundant, may act in a similar way, and such has been imagined to be the cause of cancer (*f*) and certain other affections, and the application of chemical hypothesis to therapeutics has been equally woful. What shall we say to the doctrine which teaches that it is by a kind of tanning of the several tissues that astringent medicines take effect in the several diseases in which they are used? What to that which inculcates that it is by combining with the oil of a Bronchocele, and thus converting it into a soluble soap, that soda is of service in this disease; or to that which would persuade us that it is by its affinity for the ammoniacal salts of the blood (*g*), or by its forming with the hydrochloric acid of the saliva a soluble hydrochlorate—whereas with the urine it could only have formed an insoluble phosphate (*h*)—that mercury acts as a sialagogue? What shall we say to the presumption that yeast is of service to the reputedly putrid diseases, upon the same principle as carbonic acid prevents meat from putrifying (*i*); or to that which assumes that hydrochloric acid is beneficial in the same diseases, because contagious miasms are thereby rendered inert (*j*)? What again to that which attributes the advantage of cold affusion in fevers to the decomposition of the water, and the entrance of its oxygen into the system (*k*)? But it is superfluous dwelling any longer on such wretched mummery as this. If doctrines like these were applicable at all—that is to

(*a*) Fourcroy.

(*b*) This is the hypothesis of Ackermann, differing from that of Galen, lately renewed by Rolando, with respect to the communication to the embryo of certain tissues from each parent, only in being much less tenable. We smile in our wise moments at the reveries of our predecessors; but how often do we, in our foolish moments, imitate, or even surpass, them!

(*c*) Beddoes. On the other hand, M. Baudelocque has lately, with equal probability, represented scrofula, of which phthisis is merely a node—as arising from too little oxygen, or, at any rate, as depending on too rare a renewal of the air.

(*d*) Le Cat, Marc, Kopp, &c. It is perhaps on this account that drunken old women, who may be presumed to be excessively hydrogenous in their composition, are the chief victims of this disaster!

(*e*) Rollo.

(*f*) Peyrilhe, Ewart, &c.

(*g*) Cullen, Lect. on Mat. Med. 1773.

(*h*) Murray, Materia Medica, 1828.

(*i*) Cartwright.

(*j*) Guyton-Morveau.

(*k*) Mason Good. It is fair to observe, however, that the learned writer only “throws out this hypothesis as a hint, to be prosecuted by”—those who have nothing better to do.

say, if the living body were to be regarded at any time as a merely chemical machine—they must obviously be so much more frequently than has ever been presumed; since the proportion of the principles of the blood, proximate or ultimate, if liable to be ever disturbed in the way that has been supposed, could hardly, under every slight variation of circumstances, escape disturbance, and such disturbance, if it produced the few diseases which have been stated, must have produced innumerable others; and since the operation of medicines, if even determined by chemical affinities, must have been always more or less under their influence. But the human body is regarded as a merely chemical machine only as often as it is convenient so to consider it—and while in discussing some few diseases and remedies chemical doctrines are all in all, in speaking of the great majority of both, it seems to be forgotten that there are such things as sodo-albumen or fibrin, acids or alkalies, oxygen or hydrogen in existence. Such partial hypotheses are *prima facie* suspicious; and, were this the place for discussing the subject, all which have been just alluded to might easily be shown to be individually, as well as collectively, erroneous. At present, however, it is sufficient to observe, in conclusion, that, as formerly a false estimate was made of the scope of mathematical science, in applying it to explain the *actions* of organized beings, so in recent times a similarly false estimate seems to have been made of that of chemistry, in applying it to explain either its actions or its *composition*; and that the doctrine of angles and logarithms and algebraical equations is not in general more foreign from the one, than that of definite proportions and solubilities and chemical re-agents is from the other.

The more or less rapid spontaneous decomposition of organic matters, if ternary or quaternary, when deprived of their irritability or vitality, arises from the complexity of their combination being such as rarely to allow of the affinities of any of their elements being fully satisfied. The oxygen in them, for example, is not in sufficient quantity to saturate their hydrogen and carbon—therefore they are all inflammable; and the constant tendency of all their elements to run into binary, instead of ternary or quaternary compounds, is such as to effect, under favourable circumstances, their speedy separation. The most remarkable kind of spontaneous decomposition of quaternary organic compounds is putrefaction. In this case if the substance which is about to undergo it, whether vegetable, as extractive or animal, as sodo-albumen or gelatin, be exposed to the atmosphere, it first acquires from it more oxygen, and thus are formed, with a portion of the hydrogen and carbon, water and carbonic acid. In the mean time other portions of each of the latter, uniting together, form carburetted hydrogen; while the remainder of the hydrogen, uniting with the nitrogen, forms ammonia—the distinctive product of this kind of decomposition. This process is favoured by any means which either diminishes the cohesion of the particles of the substance, or exerts an affinity for any one of the resulting binary compounds, the free access of the atmosphere being of course essential to it; and it is accordingly in the former of these ways that a moderate temperature—such as that between 60 and 80 deg. and a moderate supply of moisture, promoted of course by the contact of deliquescent salts, seem to operate; while it is in the latter way that lime and other matters generally called septic, which predispose to the formation of carbonic acid, &c. appear to act (a). On the other hand, the process is retarded by any means which either increases the cohesion of the particles of the substance, exerts an affinity for the quaternary compound as it is, or excludes the air; and it is accordingly upon the first of these principles that either great heat or great cold seems to operate, the former by drying up and the latter by congealing the moisture (b); it is partly upon the first and partly of the second principle that numerous matters, commonly called antiseptic, such as alum, nitre, sea salt, and corrosive sublimate, appear to act; while it is upon the third principle chiefly that keeping the substance in full and well-stopped bottles, or, as lately observed in carbonic acid or other gases, or smoking it, or imbuing it with wax, honey, sugar, gum, resin, balsam, pitch, oil, paint, varnish, oil of turpentine, alcohol, vinegar, and so forth, seems to produce the effect in question (c).

(a) Hence the common practice of putting lime into the coffins of persons who have died of really or reputedly contagious diseases—a practice somewhat superfluous, perhaps, since such diseases pretty certainly cease to be contagious long before decomposition, however accelerated, can take place.

(b) It is sufficiently well known that dead bodies, left either on burning deserts or in the glaciers of Alpine districts, do not undergo this change.

(c) It is remarkable how soon the prac-

tice of embalming, which originated in a belief in the celebrated doctrine of the *metempsychosis*, led to a knowledge of the influence of all these solid and liquid substances in preventing the decomposition of the dead, with the exception of corrosive sublimate, oil of turpentine and alcohol, with which mankind was not acquainted till the age of the Arabian physicians, who introduced, for the first time, the art of sublimation and distillation. The word mummy is derived from the Egyptian *mum*, or wax, as embalming is from the *balm* employed in

If, again, a substance susceptible of putrefaction be kept in water, it undergoes these changes more slowly; and, provided there be present at the same time any acidifiable matters, such as stearin or elain, the results are different from those first stated. In this case the water, if not retained undecomposed by a mixture with it of alcohol, or any other substance having a strong affinity for it, first affords the requisite oxygen, and the same, or nearly the same, results as in the former case, are produced. But now the ammonia, instead of being dissipated, seems to remain in contact with the substance, and to predispose the acidifiable matters to absorb oxygen and to become acid, which acid, subsequently uniting with the ammonia, give rise to a kind of salt, or soap, called adipocere (a). It was till lately believed that none but the fibrinous parts of animals, when interspersed with fat, were capable, under favourable circumstances, of undergoing this change; but it has been recently established that the albuminous and gelatinous parts are equally liable to it (b). Lastly, quaternary organic compounds when below ground, undergo changes, according as the soil is either dry or moist, similar to those which they undergo in either air or water, but generally speaking, more slowly than in either, particularly if they have been well enclosed and buried deep—if, however, such changes have begun to take place previously to burial, it is important to know that they are not retarded by this measure. The decomposition of interred human bodies has been said to be, under ordinary circumstances, perfect at the expiration of about three years, if the grave be four feet deep; and of about four years if it be six (c). Upon what principle it is to be explained that such spontaneous decomposition of the animal body does not always take place, even when no extraordinary means have been employed to prevent it, or certainly not within the usual period, is quite unknown; such, however, is said to have been the case in not a few very remarkable instances (d), but the authenticity of the majority of these is somewhat questionable.

**LECTURES
ON THE
PHYSICAL EDUCATION AND DIS-
EASES OF INFANTS,
FROM BIRTH TO PUBERTY,**

Dispensary, Gerrard Street, Soho;
Session 1834-35.*

LECTURE XXVIII.

*Acute, Congenital and Chronic Hydrocephalus
—Stages — Pathology and Treatment—Pa-*

*racentesis Cranii (tapping the brain) — Cases
in which the Operation is justifiable — Cases
in which it is unjustifiable — Remarks on the
various Remedies employed in Hydrocephalus.*

GENTLEMEN—I have now to direct your attention to the pathology and treatment of the varieties of effusion in the brain, or the disease called hydrocephalus. This is a subject of intense interest, and one that requires the recollection of the anatomy, physiology, and pathology, of an organ which is one of the most important in the animal economy..

the process. The ancient Jews, Greeks, and Romans commonly burnt their dead; but were accustomed to preserve their organic rarities in honey, as we do in alcohol. Savages often, in the present day, smoke-dry their dead by way of preserving them; but in some places, as Nova Scotia and Otaheite, embalming has been in use from time immemorial.

(a) This singular effect of water, as “a sore decayer of your whorson dead body,” was noticed for the first time during the extensive exhumations which took place at the Cimetière des Innocens, at Paris, about fifty years ago, and was most remarkable in those bodies which had been buried about three years. It was proposed to turn the discovery to useful purposes first by Dr. Smith Gibbs, Phil. Trans. 1794 and 1795, while the first satisfactory explanation of the *rationale* of the process was given by Chevreul.

(b) This fact has been established by Devergie, by whom the spontaneous changes of the several parts of the human body in water have been particularly investigated. (Ann. d'Hygiène Publique, 1829).

(c) Petit.

(d) It is related that the body of Tullia, the daughter of Cicero, was discovered perfectly sound in the pontificate of Paul III., after having lain in the ground fifteen hundred years; and the same was the case, according to Lactantius, with the body of Maximianus, which was disinterred at Marseilles, after eight hundred years interment. It is said, also, by Jones, that the body of Vladimir, who first introduced Christianity into Russia, is still to be seen quite entire, with that of his mother likewise, in the church of St. Sophia, at Novogorod; as is that of the Duc de Croz, covered by a glass case, in the church of St. Nicholas, at Revel. A similar story is related of the corpse of a man of the name of Bancroft, interred in St. Helen's church, Bishopsgate, London, which was annually exposed for many years, in conformity with his will, and constantly found unchanged. Numerous other accounts of this kind are on record; but they are for the most part so ill authenticated, that it would be idle to speculate upon them.

At our last meeting, I made some general observations on the nature and treatment of hydrocephalus; and I shall now place the received opinions in the simplest order, so that the youngest of my auditory cannot fail to be informed on the subject.

The history of congenital dropsy in the brain, justifies the conclusion that the treatment of intra-uterine hydrocephalus is by no means determined. It is difficult to suspend the nutritive action of the brain, caused by an increased quantity of blood in the organ, and to excite the absorption of the effused fluid. Do the remedies which strengthen the lymphatic system possess any preservative power? In adopting the affirmative of this question, M. Gardien preserved, an infant whose four brothers had died between the fourth and fifth month of hydrothorax (Capuron). It generally happens that a woman has seldom more than one hydrocephalic infant; but if her offspring were remarkable for large heads, analogy would justify the use of remedies during utero-gestation. When the disease becomes chronic, or appears after birth, a variety of remedies are employed, and these are varied according as the disease is acute or chronic.

Acute Hydrocephalus.—This disease generally affects children before the seventh year, from this age to puberty, and rarely adults. It is preceded by lassitude, slight fever, pain or heaviness of the head, and then slow labouring pulse, dilated pupils, somnolence, drowsiness or stupor.

Hydrocephalus usually attacks children of a scrofulous habit, but others free from any disposition to this disease. It is divided into a febrile stage, a stage of stupor, and a stage of effusion.

Symptoms of the Febrile Stage.—Languor, lassitude, loss of appetite, thirst, peevishness, pain in the head, frequent or constant vomiting, tongue white, bowels obstinately confined, skin hot, countenance pallid or flushed, intolerance of light and sound, frequent, sharp, strong pulse, fever remittent, generally increased towards evening, pulsation of the carotid and temporal arteries; excessive pain in the head, restlessness, screaming, pulse 130 to 160, respiration accelerated and soon retarded, great moaning, and finally stupor.

Symptoms of the Torpid Stage.—Pain in the head and vomiting increased, incessant rotation or rolling of head, grinding or gnashing of the teeth, pulse slow, or rapid; rubbing of the forehead with the hands, or raising the hand towards the forehead, strabismus or squinting, respiration at one moment slow, and another rapid, sensation diminished, vision, audition, olfaction, gustation and palpation decreased or suspended, obstinate costiveness, retention or incontinence of urine.

Symptoms of the Stage of Effusion.—The vomiting ceases, the stupor is profound for some time, the pupils are dilated, the pulse is remarkably slow, or frequent, sometimes so high as 200 or 250, vision is lost, there is paralysis of one or both sides of the body, great groaning, convulsions, clammy cold sweat on the extremities, a diminution of these symptoms, or death, closes the scene.

The exciting causes are injuries on the head, frequent stooping or incurvation of the body, in which young children very much indulge, excessive exercise, exposure to great heat, hooping-cough, dentition, measles, scarlatina, small-pox, sudden disappearance of other eruptions of the skin, convulsions, infantile remittent fever, &c.

The predisposing causes are excessive development of the brain, scrofula, and a debilitated constitution.

Diagnosis.—Hydrocephalus is frequently mistaken for vermination (worms), marasmus, infantile remittent fever, and dentition.

In cases of worms, the appetite is variable, sometimes absent, sometimes voracious; the bowels are very much relaxed or confined, the pain in the head is periodical or intermittent; and worms are sooner or later expelled.

In hydrocephalus, there is a large head with copious capillary growth, there is constant want of appetite, the bowels are obstinately confined, the pain in the head is constant and excruciating, there is intolerance of light and sound, pulsation of the carotid and temporal arteries, heat of the scalp, &c.

In marasmus, the febrile symptoms are absent or remittent, but seldom constant. In infantile remittent fever, the infant is feverish in the evening, or at some particular hour of the day; at other times apparently well, but debilitated, until the feverish symptoms return. In acute hydrocephalus, there is scarcely any well marked remission of the symptoms, vomiting does not relieve the pain in the head, but usually increases it; intolerance of light and sound continues, as well as the increased action of the arteries of the head and neck.

The diagnosis of dentition and hydrocephalus may be easily established. The state of the gums, the copious flow of saliva, the elevation of the hand towards the mouth, the pain caused by warm or cold fluids when taken into the mouth, the pain on pressing of the gums, and the removal of all these symptoms by incising or cutting the gums, enable us to form a correct diagnosis. Incision of the gums will not relieve the symptoms of hydrocephalus; the pain in the head will continue after the operation, so also will the intolerance of light and sound, the obstinate constipation, the remarkable dejection of the countenance, the vacillation of the pulse, the inability of the patient to re-

tain the erect posture, the stridulous or sharp intonations of the voice, the squinting, dilated pupils, constant rotation or rolling of the head, grinding or gnashing of the teeth, coma, or frequent convulsions, paralysis of one or both sides, and laborious or difficult respiration, which characterise hydrocephalus.

The prognosis is favourable when the disease is treated in the first stage, when the bowels are steadily acted on by medicines, when vomiting may be speedily relieved, when the remedies employed are efficacious, and when the headache, pulsations of the arteries, and fever are controllable.

The prognosis is unfavourable, when the first stage passes rapidly into the second, if the strabismus, dilatation of the pupils, coma or convulsions are present; when there is gnashing of the teeth, convulsions, rolling of the head, paralysis of one or both sides, blindness, the pulse being very slow or rapid, the prognosis or result is very unfavourable.

Pathology of acute Hydrocephalus.—M. Charpentier, in his work—*De Nature et du Traitement de la Maladie Hydrocephale aigue (meningo-cephalite des Enfants)*, 1829, informs us that he observed the disease at the Hospital des Enfants in Paris, in 1824, and denies the conclusions of many of his predecessors.

After the most sober reflection on all the facts, reasonings, and analogies put forth by former writers, he contends that the effusion of fluid into the ventricles does not constitute the disease, that it is but the effect—an effect much less important than is thought, because it does not modify the progress, the symptoms, or reveal its own presence, and does not offer any particular curative indication. He thinks the term acute hydrocephalus extremely unfortunate, as it gives a false notion of the cause and treatment of the disease. He considers the brain, and not its membranes, the primary seat of the disease; and in proof of this opinion, he refers to the symptoms, the progress of the malady, and the appearance of the organs after death. After a long discussion on these points, he concludes that acute hydrocephalus is a combined inflammation of the brain and its meninges—a meningo-cephalitis, but most frequently it is not discoverable in which tissue inflammation commences. He is of opinion, that the condition of the brain and its membranes which constitutes hydrocephalus in infants, produces atonic fever (low nervous fever), in an individual more advanced in life, and serous apoplexy in the aged. There is in fact a simple difference of form, but not of nature. He combats the assertions of MM. Parent, Martinet, and Serres, who attribute the symptoms of acute hydrocephalus to arachnitis at the base of the brain, referring arachnitis of the convexity to adults, especially in atonic fever, the essential character of which is delirium. In fact these writers

assert that delirium exclusively depends upon meningitis on the convexity of the brain. M. Charpentier very justly asserts the contrary, for in the greatest majority of cases of arachnitis in the basis of the brain, he observed traces of inflammation at the same time on the membranes of the convexity, and he considers the defect of delirium in cerebral affections of infants, as dependent on the state of the intellectual faculties in the first years of life, and his opinion seems well founded, for in 125 cases of meningitis reported by the writers already named, delirium was not observed before the eighteenth year, and there was arachnitis on the convexity in thirteen cases, the subjects of which were under that age. It is to this difference of age M. Charpentier properly ascribes the hydrocephalic cries, and the frequent convulsions; but he thinks the dilatation of the pupils, their oscillations, and their insensibility, rest upon this—that the base of the brain is oftener affected in infants than in adults. Dr. Abercrombie asserts that the seat of effusion varies in different cases; it is found in the ventricles, under and over the arachnoid, between the layers of the septum lucidum. He also has shewn that the effusion depends on inflammation in the substance and central parts of the brain, and that it terminates by remollissement or softening. M. Martinet observes, in his *Pathology*, speaking of the morbid appearance in acute hydrocephalus—"The arachnoid membrane lining the lateral ventricles and base of the brain, presents no alterations on the convexity; it is rather dry: the superior convolutions of the hemispheres are depressed and flattened, and when touched give a sense of fluctuation; the lateral ventricles, considerably dilated, are filled with a limpid, straw-coloured fluid, without any flocculi; the dilatation is most manifest towards the digital cavity; the third and fourth ventricles are considerably enlarged. Sometimes no fluid is found in the ventricles, though dilated, which arises from the fluids being absorbed immediately before death had occurred. The pia mater enveloping the external surface of the brain, may be injected with blood, but this is not a very frequent occurrence, and should not in any case be considered as the cause of the effusion into the ventricles. Finally, when the disease has lasted for a considerable time, the digital cavity, the fornix, and corpus callosum may become softened, in the same way as has been described when treating of arachnitis of the ventricles." It must be admitted, however, that his conclusions seem founded on observation and pathology; but he must be aware that the writers of this country have long since maintained the views now propounded—that the effusion of serum was the effect, and not the cause of hydrocephalus. The disease is generally treated upon this pathology by nearly all British practitioners.

But this pathology is not received by all medical men in this or any other country, because considerable effusion of serum may be found in the cerebral ventricles of infants and adults, and no morbid lesion of the cerebro-spinal organs discoverable. It is unnecessary, I presume, to cite authorities on this point, which is universally admitted. I therefore think Charpentier has gone too far in dogmatically pronouncing meningo-cephalitis the morbid state which invariably induces effusion into the ventricles. The term meningo-cephalitis, proposed by M. C. is not more accurate than that already employed.

Upon a review of the opinions of this author, I find it necessary to make a few further comments. In the first place, he has been anticipated in his views of the morbid state of the brain, to which he very improperly refers every form of acute hydrocephalus. His countryman, M. Itard, had partly arrived at the same conclusion, that inflammation of the brain or its membranes produced the effusion. (*Dict. des Sci. Med. art. Hydrocephale.*) But Drs. Beddoes, Withering, Carmichael Smith, Quin, Rush, Cheyne, Yeats, and Ayre, had published similar opinions long anterior to either of the former writers. Again, we have the testimony of Quin, Cheyne, Warren, and Golis, that all the symptoms of hydrocephalus may be present, and no effusion found on dissection. Dr. Shearman is also of opinion, that the disease does not depend on inflammation, it is the result of excitement, favoured by fever and predisposition. We have also most respectable evidence against this author's opinion, that hydrocephalus is always an idiopathic disease of the brain. Hoffman considered stagnation of fluids in the duodenum a remote cause of cephalalgia, vertigo, torpor of the senses, and apoplexy. Dr. Cheyne maintains that hydrocephalus arises from sympathy with disease of the liver, and Dr. Anthony Todd Thomson adds his testimony in proof of this opinion, as he found the liver affected in nine cases out of eleven. Dr. Yeats also asserts, that the disease commences in organs remote from the brain. M. Itard states, that when the pain in the head is diminished, the epigastric region was painful on pressure. This writer is also of opinion, that irritation of the brain is sometimes a cause of the disease, and in some cases dentition, gastric and encephalic inflammation, extends to the stomach. He found the stomach the organ generally affected, next to the head, the intestines ulcerated, or invaginated, and the liver rarely affected. On the other hand, Dr. Golis informs us that he found all the alvine viscera generally healthy. In fact, M. Itard has anticipated the pathological views of this author, and published an essay on hydrocephalus, very far superior, both as to the nature and treatment of the disease.

Treatment.—The remedies in the first febrile or inflammatory stage of the disease are general and local bleedings, leeches to the base of the skull behind the ears, and on the neck over the course of the jugular vein, opening the jugular vein or temporal artery, repeated purgation with calomel, scammony, and other drastic remedies, croton oil, &c., the warm bath, with cold to the head while it is being employed, the cold dash or pouring cold water in a small stream through the pipe of a teapot, &c., cold or iced lotions to the scalp, mustard cataplasms, or fomentations to the legs and feet, friction on these parts with warm oil of turpentine, or blisters applied to the legs, thighs, or between the shoulders, to the nape of the neck, and lastly to the scalp.

In the second stage, when torpor supervenes, the free use of calomel in small and repeated doses, every second or third hour, mercurial inunctions over the angles of the jaws, on the axilla with a drachm of strong mercurial ointment every second, third, or fourth hour, according to the urgency of the symptoms. When the pulse is rapid, from 120 to 160, tincture or infusion of digitalis, and nitrous æthis are advisable.

Even in this stage, depletion is indicated, when the countenance is flushed, the pulse strong and sharp, the arteries of the head and neck pulsating, and the scalp hot.

In the third stage, when effusion has taken place, the indication of treatment is to cause its absorption by mercury, iodine, purgatives, diuretics, squill, digitalis, &c., &c.

Dr. George Armstrong was the first who reported three cases treated by mercurial frictions, and the internal use of calomel and oxymuriate of mercury. (*Treatise on Diseases of Infants.*) Six other cases successfully treated by the same remedies are recorded in the *Edinburgh Medical Commentaries*, and a seventh which was very much relieved. Professor Murray of Gottingen, speaks most favourably of mercury in his work on *Diseases of Infants*. Many eminent writers have strongly recommended the various medicines already mentioned—depletion, purgatives, refrigerents, and diaphoretics to abate febrile or inflammatory action, and to prevent effusion, and when this has happened, purgatives diuretics, mercurials, blisters, &c.

M. Charpentier has made the most serious omissions in the treatment. He has not recommended venesection, so much lauded by Beddoes, and we believe by Withering, Mills, Maxwell, Rush, and others. Dr. Maxwell asserts, that he cured sixty out of ninety cases by copious depletion. Dr. Beddoes considered depletion as necessary in this disease as in pneumonia. Dr. Golis recommended arteriotomy. But to this it may be replied, that excessive depletion causes effusion into the ventricles of the brain. Again,

Charpentier has omitted to mention the internal and external use of mercury. Dr. Percival was a strong advocate for this remedy, also Drs. Dobson, Mills, Cheyne, Fisher, Itard, and Jadelot. The last physician recommends mercurial inunction to the scalp, and repeated doses of calomel daily. Mercurials and antimonials are very generally employed in this country. Dr. H. Davis treated the disease successfully with mercurial inunction, calomel, and digitalis. Dr. Carmichael Smith employed calomel and squills, as also M. Labonnarderie, and Itard, squills and digitalis. Bricheteau and Flajani, laud squills alone. M. Itard is a strong advocate for the vapour bath, and the various remedies already enumerated, as well as those proposed by M. Charpentier. In addition, he advises repeated blisters to the extremities, neck, and head; in obstinate cases, moxa to the vertex, and a seton in the neck. Dr. C. Smith applied caustic to the vertex.

When depletion, purgation, counter-irritation, &c. have failed, some have advised a seton in the neck, moxas, antimonial ointment, repeated doses of calomel, 2 or 4 grains every second or third hour, or combined with James's Powder, while others advise nauseating doses of tartarized antimony. Martinet used frictions with squills and digitalis over the limbs and body, when the disease became chronic. MM. Recamier and Andrieux prescribed a bath composed of a pailful of water, and one ounce of tartarized antimony. I have used frictions with iodine advantageously. The following case now under treatment, and repeatedly observed by you all, proves the value of this remedy.

G. D. aged two years and a quarter, was admitted under my care at the Western Dispensary in November last. Her mother observed that the head of this infant was remarkably small at birth, but at the end of six weeks began to enlarge, since which time it has continued to do so. It now measures twenty-three inches in circumference. The infant has no power of voluntary motion, vision is lost, there is strabismus, almost constant moaning, the appetite is bad, the alvine dejections unhealthy, sometimes white, brown, and very offensive. The anterior and posterior fontanelles are enlarged, and the sutures are unossified. The parent stated that her parturition with this infant was natural. The digestive function was improved by calomel and rhubarb, with aromatic powder; and the head was rubbed with a drachm of the following ointment night and morning:—hydriodate of potass, $\mathfrak{z}\text{j}$, adeps $\mathfrak{z}\text{j}$,—she was also ordered a mixture composed of acet. potassæ gr. x , aq. $\mathfrak{z}\text{iss}$, syrup $\mathfrak{z}\text{iv}$: $\mathfrak{z}\text{j}$ 3 in die.

These remedies were continued for a month, during which the head decreased half an inch in circumference. The intellectual powers

began to develop, the appetite improved, alvine dejections became natural. The hydriodate was now substituted for the acetate, but this did not act as a diuretic or absorbent. The child continued to improve until Feb. 3rd, 1835, when she had acet. potass $\mathfrak{D}\text{ss}$ a. q. $\mathfrak{z}\text{ij}$; $\mathfrak{z}\text{i}$ 3 in die. 18th. The remedies are continued.

A few years since, this case would have been considered beyond the power of medicine; indeed, no remedy, except an occasional aperient, would be prescribed. But the success of Dr. Conquest and Mr. Russell in curing chronic and even congenital hydrocephalus by paracentesis cranii (tapping the brain), has convinced the profession of the propriety of employing remedial measures. Lecat was the first to propose tapping the brain, according to Capuron; but the operation was rejected as rash by Camper. "This operation," says M. Capuron, "cannot repair the injured state of the brain when it is partially or totally destroyed. It therefore appears to be condemned and disapproved of by nature herself, as infants always perish when the meninges (membranes of the brain) and scalp are spontaneously lacerated.—*Traité des Maladies des Enfants*. Such was the opinion of the learned and experienced French professor some years ago; but he has lived to see it controverted by many successful operations.

According to Professor Velpeau, another distinguished French writer, tapping of the brain was proposed by Vose and Holbrook. It was, I believe, first performed unsuccessfully in this country by Mr. Angus, of Liverpool, and next by Mr. Callaway, of Guy's Hospital. But Dr. Conquest, late of St. Bartholomew's Hospital, was the first practitioner in this, and perhaps in any other country, who performed it successfully. The following is his account of the operation, as published in the London Medical Gazette, 1830. He introduced a trocar obliquely—

"Close to the edge of the right frontal bone, about midway between the crista galli process of the ethmoid bone and the anterior fontanelle, so as to avoid the longitudinal sinus on the one hand, and the corpus striatum on the other. The instrument entered about two inches below the scalp. An ounce and a half of bloody serum, mixed with portions of cerebrum, escaped. The pulse became feeble, and temporary collapse followed. The fluid was allowed to escape stillicidium, and within eight-and-forty hours about two pints and a half flowed out of the opening. Almost immediately after the operation, the pupils became sensible to the stimulus of light; the drowsiness was succeeded by disinclination to sleep, and the pulse, which had always before been remarkably slow, became about eighty-five. Two days after the operation, the brain evidenced signs of inflammation, with high constitutional disturbance; and great alarm was excited by a rather formidable at-

tack of convulsions. Leeches to the temples, and the constant application of cold to the head, subdued the local inflammation, and within four-and-twenty hours all became tranquil. The head was well strapped, and from the cessation of cerebral excitement no unfavourable circumstance occurred.

"When this interesting child was exhibited to the class on Saturday evening, every one was struck with the improvement of its appearance, and by the intelligence and cheerfulness of its countenance." Dr. C. stated that he considered it perfectly well, and as exhibiting a most gratifying and triumphant proof that this seemingly formidable proceeding might be safely and successfully adopted under similar circumstances.

The other case, to which the doctor has often adverted during the winter, he operated on last autumn, assisted by Dr. Hodgkin, the talented pathologist of Guy's Hospital. Nine ounces of serum were withdrawn from the posterior fontanelle. The head became lessened six inches in circumference, and no increase in its size has yet recurred.

When I was about to edit the last edition of Dr. Hooper's Physician's Vademecum, which the celebrated author declined, on account of indisposition, I requested Dr. Conquest to favour me with an account of his success in tapping the brain. He very politely and readily complied with my request, in these terms:—

"My first successful operation was performed at St. Bartholomew's Hospital in the autumn of 1829, when only $\frac{3}{4}$ iss of serum escaped, but during the subsequent two days, not less than $\frac{3}{4}$ xiv flowed. The child had been the subject of frequent convulsions, &c. before tapping; but only one paroxysm followed. Two years afterwards the child was in perfect health. The second patient was tapped thrice; first on the 20th of November, when $\frac{3}{4}$ xij of serum were taken away; secondly, on the 2nd of December $\frac{3}{4}$ viij were evacuated; and on the 16th $\frac{3}{4}$ ij. Dr. Hodgkin assisted me in this case.

"The third terminated fatally after drawing $\frac{3}{4}$ lvijss by five operations, a fortnight intervening between each.

"The fourth case was and is a patient of Dr. Caldwell of the City Dispensary. $\frac{3}{4}$ xxiv of serum were taken away by two operations, $\frac{3}{4}$ xij of fluid escaping each time, a month having intervened between them."

In the *Lancet* of September the 15th, 1832, Dr. C. details the case, and states that at the end of two years the child continues well.

"The fifth patient is a child yet living, but will eventually die. I have tapped it four times since February, 1832, and taken away $\frac{3}{4}$ xlv altogether. I believe the child would have recovered had the parent consented to one or two more operations.

"I have operated on five other cases; in one instance the child survived (two tappings,

one of $\frac{3}{4}$ xvj, the other of $\frac{3}{4}$ xij) six months, and then died of hooping-cough. In another case, the infant lived some months, and was carried off by teething. Another case is yet under my care, promising to do well, having been tapped three times, and the others ended fatally." December 7, 1832.

Mr. Russell, of Aberdeen, details the following case. A fine trocar, such as is used for hydrocele, was introduced into the head of a female infant aged eight months, about half an inch in depth on the right side of the anterior fontanelle; and three ounces of serous fluid were discharged through the canula. A piece of adhesive plaster was applied over the wound, and a roller round the head. A slight degree of fever followed. In ten days afterwards a similar puncture was made on the opposite side, and five ounces and a half of turbid serum were evacuated. No unfavourable symptom followed. In five days afterwards the head was diminished two inches and a half in circumference, and two and a quarter across the vertex. In a fortnight after the last operation the trocar was passed near the first position in an oblique direction into the ventricle, when nine ounces of serum escaped in a continued stream. The pulse became weak and feeble, and she became faint; but she soon revived, and no bad symptom followed. She recovered completely, and became a lusty child of her age. —*Edinburgh Medical and Surgical Journal*, July, 1832. *Vide Dr. Hooper's Physician's Vademecum*, 1833.

I need scarcely remind you that the experiments of various modern physiologists who incised the brain without destroying the lives of the lower animals, and the fact that musket balls have been lodged in that organ for a long time with impunity, and even a great portion of the hemisphere were often destroyed. Hennen, Larrey, and Cooper, shew the feasibility of the operation under certain considerations. A British practitioner is entitled to the honour of having established the operation of tapping the brain! The operation will henceforth be performed when circumstances demand it. Some of our Gallic contemporaries appear unacquainted with the progress of surgery in this country. Thus, the late M. Billard, the indefatigable observer of infantile diseases, and upon the whole one of the most experienced in infantile pathology of modern times, thus expresses himself:—

"I believe it will be difficult to establish the treatment of this disease (congenital hydrocephalus). How can we diminish the nutritive activity of the organ (brain), and effect the absorption of the effused fluid? Nevertheless, authors have advised different means, among which I shall particularly state mercurial frictions. These were first employed in this disease by Armstrong (George); and Lefebure de Villebrune has detailed, in his translation of Underwood, many cases by

Armstrong and Hunter, in which the efficacy of this remedy is evident. But it is to be remarked, that the infants who were the subjects of this disease were advanced in age, and presented the symptoms of acute or chronic meningitis before the simple effusion of serosity into the cerebral ventricles. I therefore think it useless to try any remedy when hydrocephalus is not caused by any particular accident, and that we must confine ourselves to hygienic measures, of which the chief object should be to avoid all cerebral excitement. If meningitis should supervene, we must have recourse to the remedy which I have advised in giving the history of this disease."—*Traité des Maladies des Enfants Nouveau-Nés et à la Mamelle; Deuxième Edition, &c.; Par M. de Olivier (D'Angers), 1833.*

It appears from the statements already advanced in this lecture, that tapping the brain is not justifiable until all other remedies have failed. It is also evident that the operation is safe and successful even as a last resource.

It is important to be aware of the fact, that mercury, when used in excess, has produced the worst results. Though it is barely possible to salivate a child afflicted with hydrocephalus, yet destructive gangrene of the cheek and gums has been frequently induced by mercury; and the lower jaw has been separated from its fellow by this remedy. A practitioner, whose self conceit and vanity far exceeded any thing I have ever observed or imagined, and who was a most ignorant person withal, prided himself on having arrested hydrocephalus by mercury, though the articulations of the inferior jaw-bones were destroyed, and the miserable infant was deprived of the lower part of the face. I need scarcely state that it died in a short time, notwithstanding the cure of its hydrocephalus! Every experienced and rational practitioner well knows, that in urging mercury in excess, he runs a great risk, and can never calculate upon the consequences. Digitalis is also a most dangerous remedy, in truth, a powerful poison when administered too freely. I am well aware that dangerous remedies ought to be tried, when all others have failed, and when a disease appears to be hopeless; but they are always administered in such cases, by experienced practitioners, with caution, and often with dread. It is of little consequence whether an infant dies of hydrocephalus, or the bad effects of mercury or digitalis. We should always remember the infantile constitution; and if we do, we shall invariably urge dangerous remedies with fear and trembling. We have now the satisfaction to know that tapping the brain is successful when all medicines have failed. But this operation cannot be performed in acute cases. A child may be destroyed by congestion of the brain without an effusion, or with a small quantity of effusion; and in such cases the brain, or its membranes, are not only inflamed or congested, but the substance

of the former may be slightly, if thinned at all. It is, therefore, one thing to pass a sharp instrument through a brain as thin as paper, a condition common in congenital or chronic hydrocephalus, and another, through an organ of ordinary thickness. Lastly, we should never forget that all the symptoms of hydrocephalus and of apoplexy, may be present in cases of congestion of the brain or its membranes, without any effusion whatever; and therefore, it behoves us to be extremely cautious in proposing or employing tapping of the brain, unless the history of the case justifies such a proceeding. There is another practical observation worthy of remembrance in treating diseases of the brain. It is the impropriety of applying leeches, cupping, or blisters on the scalp. These only increase the determination of blood in the affected organ. (Sabatier, Copland, Graves, &c.). Dr. London of Leamington caused the greatest tumefaction of the breasts in amenorrhœa, by repeated applications of leeches to the mammae; and the late Mr. Ware had previously observed, that the application of leeches round the eye, greatly aggravated ophthalmia. Looking at the circulation of the blood as a circle, I feel convinced that more good will be done by applying leeches round the arms, to the thighs, or other parts remote from the brain in hydrocephalus (a practice adopted by our continental contemporaries), than by applying them directly to the scalp. The application of a small stream of cold water to the head (cold dash) while the patient is in the sitting posture in a warm bath, is also scientific practice. The cold lessens the quantity of blood in the brain, while the warmth determines it to all the rest of the body. The warm bath, unless cold be applied to the head at the same time, will and must do more harm than good. It is also most important to keep the head raised, so as to facilitate the return of the blood from it. The constant application of cold or freezing lotions, bladders of cold water, ice, snow, &c. to the head, has often preserved life, when every thing else has failed.

Counter-irritants to the lower extremities are of immense value in acute head affection. But they must not be applied too long, or they will induce ulceration, gangrene, or sloughing.

But there are some cases of congenital and chronic hydrocephalus, in which the substance of the brain is reduced by the absorption caused by the pressure of the effused fluid to extreme tenuity, to the thinness of gauze, in which all remedies are useless. Suppose a brain so constituted was tapped, we could not possibly expect, that the organ might regain its pristine consistence and substance. The probability would be, that if we drew off the effused fluid to day, it would be regenerated to-morrow. But if our patient was young and undeveloped, our prognosis would be the more favourable; because

in such cases, hydrocephalus may exist to a certain extent, without causing destructive absorption of the cerebral substance. It would be one thing to see a child confined to the recumbent position, deprived of sense and motion, with the head inordinately enlarged; and another to observe it with diminished sense and motion, but in the partial enjoyment of its intellectual and physical powers. In the latter case, the operation of tapping would be infinitely more feasible. It is therefore obvious, that paracentesis cranii, or tapping of the brain, must not be resorted to unless in certain cases of hydrocephalus.

In conclusion, I have to inform you, that mercury has been administered in immense quantities in chronic hydrocephalus, and that it finally effected a cure. This practice was rash, but it is considered right to follow the old maxim—in dangerous diseases we must use dangerous remedies. When every thing else has failed, and our patient is considered in a hopeless condition, we are justified in administering any remedy, though a violent or dangerous one, which has effected a cure under such circumstances. In hydrocephalus, or other diseases of the brain or its membranes, I am decidedly opposed to the application of leeches to the temples or scalp, to blisters, moxas, issues, or setons; as every one of these must increase determination of blood to the brain and scalp, and do much more harm than good. I can fancy cases in which the pressure of serum or blood on the brain, or a congestion of brain or its membranes, may dull sensibility, may even obliterate it in the head; and in such cases only are the remedies I object to justifiable. I feel convinced that the indiscriminate use of these remedies in acute diseases of the brain only expedite the fatal termination.

Rebiew.

An Inquiry into the Nature and Properties of the Blood in Health and in Disease. By the late Charles Turner Thackrah. Edited by Thomas G. Wright, M.D. To which is added a Biographical Memoir of Mr. Thackrah. London. 8vo. 1834. pp. 246.

(Concluded.)

THE fifth chapter is on the diversities of property in blood from different vessels of the same order. This is a subject which has nearly escaped the attention of preceding physiologists; it is, however, one of considerable interest, and has been illustrated by Mr. Thackrah in a series of experiments.

We have only room for some of the most important inferences. From a comparison

of blood taken from the jugular vein and vena cava inferior, it results—

1. That concretion* almost always takes place sooner in blood from the cava than in that from the jugular.

2. That the solid contents are larger in proportion in jugular than in caval blood.

3. That the proportion of fibrine is less uniform in jugular than in caval blood.

Our author's next observations were made on the blood of the vena portæ, and his conclusions are—

1. That the blood from the vena portæ is darker and of a browner tinge than that from other veins; that it has not the homogeneous character of other blood, and that its appearance gives the idea of defective elaboration.

2. That there is no marked difference between the specific gravity of portal blood and that of blood from other veins, or from arteries.

3. That in ordinary circumstances portal blood concretes much sooner than blood from other veins.

4. That portal blood contains about 1-10th to 13-10ths more serum than blood from other veins.

5. That the process of coagulation is slower and less perfect in portal than in jugular blood.

6. That the serum of portal differs in colour from that of jugular blood.

"Portal serum is always red; while jugular, if agitation be avoided, is straw coloured. The hue of the portal evidently depends on the detention of red particles of the blood. Does this detention arise from a difference in the sp. gravity of these particles? or from a diminished power in the crassamentum to attract or envelope them? or from a change in the serum, enabling it to hold in solution what other serum precipitates?"

"With the view of throwing some light on these questions, a definite quantity of the serum of portal blood was poured on the crassamentum of jugular blood, and a like quantity of the serum of jugular blood, taken from the same animal at the same time, poured on portal crassamentum. At the end of twenty-four hours the fluids were separated as carefully as possible from the solids. We found, in the first place, that

* By the term *concretion*, the author means, throughout the work, the *commencement* of the process of coagulation.

we could not obtain from the portal crassamentum the quantity of serum that had been poured on it: about one-sixth part was lost in the coagulum. The whole of the serum added to jugular crassamentum, on the other hand, was re-obtained without difficulty. In the next place, we observed that jugular serum which had been poured on portal crassamentum attained the red hue always seen in portal serum. Finally, the weights showed that the jugular serum had gained more from portal crassamentum than portal serum from jugular crassamentum.

"These observations, made in three experiments, led to the opinion that the difference uniformly remarked in the colour of portal serum, does not depend on a peculiar power in this fluid of absorbing or holding the red particles in solution, but on the state of the crassamentum, in portal blood."

7. That the specific gravity of portal serum, when merely poured off from the coagulum, is rather greater than that of jugular, when poured off in the same manner; this, however, probably arises from the detention of red particles in the former.

8. That portal serum concretes more quickly, but less completely, on the application of heat, than jugular.

9. That the disposition to putrefaction is less in portal than in jugular serum; the former yields a peculiar animal odour, while the latter emits a pungent ammoniacal smell: the same remark is true of the dried contents of the two kinds of serum.

10. That portal serum affords more solid matter than jugular; this however arises from the red particles detained in the former, since, when separated from these, portal serum appears to contain no larger, but probably even a smaller, proportion of solid matter than jugular.

11. That the crassamentum of portal blood is always of a looser texture than that of jugular, and contains serum up to the period of putrefaction.

12. That portal blood contains, in general, a much smaller proportion of fibrine than jugular.

13. That portal blood in general contains a much less proportion of albumen and hæmotosine than jugular.

Mr. Thackrah makes the following physiological reflections on the results of his experiments on portal blood:—

"The less elaborated and more liquid state of portal blood tends to show a source of

supply not generally supposed. If this blood be less rich, we can refer the difference only to the admixture of a diluent. And whence can this fluid be derived? Only, I conceive, from those surfaces on which we find the ramifying origins of the vein: the alimentary canal, and the stomach in particular, present a source of supply. Much of the liquid we drink is taken up, I conceive, by vessels which open directly into the radicles of the vena portæ, and thus enters the circulation without passing through the route of the lacteals. To physiologists it has long been a matter of observation and surprise that certain drinks show themselves in secretion much too soon to have traversed the intestinal lacteals, mesenteric glands, thoracic duct, and general circulation. Here we have a probable explanation of the fact. The fluid received into the stomach is rapidly taken up into the vena portæ, transmitted through the hepatic veins into the cava, and thence thrown into the current of the circulating blood.

"From the muddy character of portal blood, the tardiness and imperfection of its coagulation, and of the coagulation of its serum by heat, it seems probable that something more than water is taken up by the vein. Is it albumen in an imperfect state of elaboration?—The comparative rapidity of concretion arises, perhaps, from a lower state of vitality in the vessel.—The quantity of albumen is on the whole less in portal than other blood, but this does not militate against the supposition that a quantity of fluid, as taken up by the radicles of the vena portæ, contains a portion of this substance in an imperfect state."

He concludes the chapter by observing—

"Blood from the vena cava was examined in many of the experiments which investigated the contents of the vena portæ, as contrasted with those of the jugular. A considerable diversity was found, but the details are not sufficiently numerous and accurate to lead to any positive inferences. I may state, however, my conviction that there is a great difference in the state of the blood in different parts of the circulation, and consequently that the general opinion is incorrect, which considers the blood uniform in every thing but colour. I may hint also my suspicion that if the contents of four or six large vessels in different parts of the body were examined, no two specimens would be found the same, or even nearly the same, in their constituents and proportions. This opinion, if proved to be correct, may not be unimportant in therapeutics.

"Blood is a varying fluid. It varies every moment even in the same vessel; and at no time can we obtain blood with the same proportion of elements from two vessels even of the same order and size. The current of circulation is, like the stream of human life, incessantly pursuing its round, but as inces-

santly changing its elements. Sometimes much is thrown out of the blood by the secretions; sometimes much is taken up by the veins or lymphatics: and this contrast and variety are as applicable, I believe, to a single vessel as to the whole system. We at once see both the importance of this property, and the difficulty which it presents to the physiological investigation of this chapter. No two blood-vessels will yield at one time a fluid precisely similar; and I conceive that ignorance of this fact has occasioned many of the errors and the discordant statements of experimenters on the blood."

The sixth chapter, on the differences between arterial and venous blood, is added by the editor, who has incorporated with it some experiments illustrative of this subject, which the author did not live to prosecute according to his intention. The following experiments and observations on the chemical analysis of the two kinds of blood are worthy of observation:—

"Chemical Analysis has detected only slight differences in the composition of these two fluids. Arterial blood generally appears thinner, and yet it is found to exude less serum than venous. Its odour is also stated to be more pungent. Dr. Stevens asserts, that 'there is not one particle of free carbonic acid in healthy arterial blood,' but 'that it exists in the venous, even in that of the smallest veins.' Mr. Thackrah has ascertained the relative proportions in two instances.

"Exp. CLVI. Portions of blood taken from the femoral artery and the jugular vein of a small dog, analysed twenty-four hours after being drawn, were found to contain—

Arterial Blood.			
Serum	439.6	or 10 : 12.7.	
Crassamentum	560.4		
<hr/>			
	1000.0		
Venous Blood.			
Serum	515.2	or 10 : 9.0	
Crassamentum	484.8		
<hr/>			
	1000.0		
Dried fibrine.....	1.8		2.4
— serum.....	45.4		41.0
— crassamentum, 106.0			130.4
Water	846.8		826.2
<hr/>			<hr/>
	1000.0		1000.0

Exp. CLVII.

Blood of a dog from the		Jugular vein.	
axillary artery.			
Dried fibrine.....	3.0		3.2
— serum.....	53.0		40.7
— crassamentum, 209.0			194.5
Water	735.0		761.6
<hr/>			
	1000.0		1000.0

"Of their ultimate constituents MM. Maccaire and Marcet have detailed the following average:—

In Arterial Blood.			
Carbon.	Oxygen.	Nitrogen.	Hydrogen.
50.2	26.3	16.3	6.6
In Venous Blood.			
55.7	21.7	16.2	6.4

"In this table we observe that venous blood contains 5.5 per cent. more carbon, than arterial, and is deficient in almost an equal proportion of oxygen. The changes which take place during respiration satisfactorily account for this, as shown by the interesting experiments of Priestley, Lavoisier, Davy, Allen and Pepys, Dr. Edwards, and many other distinguished philosophers, to whose writings it is unnecessary further to allude. Dr. Dalton ascertained that eleven ounces and a half of carbon were taken into the stomach daily by a person in ordinary health, in his solid and liquid food, and an equal quantity daily given off from the body, of which ten ounces and a half are supplied from the venous blood, and expired in the form of carbonic acid gas."

The seventh chapter treats of the influence of different states of the animal system on the blood. We shall here only notice those points which the author has illustrated by original observations:—

Effects of Digestion and Diet.

"Digestion and Diet have, of course, a great effect on the blood. When the digestive organs are impaired, the chyle must be different in quantity or quality, and the blood consequently degenerate from a state of perfect health. Habitual vomiting is said to reduce the proportion of red matter, and to increase the element of water. Fasting will be expected to have a similar effect."

The following are the general conclusions, from numerous experiments, on the effects of fasting; the blood was taken from the jugular veins of dogs at different periods after feeding, but the effects of extreme inanition were not investigated:—

"The specific gravity of the blood was examined in many cases; but some doubt as to the accuracy of the several observations leads me to omit them. I may state, however, that they exhibited a universal superiority of specific gravity in the blood of dogs which had fasted.

"From the preceding table it appears, that blood from the fasted animal does not so quickly concrete; that its serum contains a proportion of albumen about equal to that from one recently fed; that its crassamentum yields rather more læmatosine, albumen, and fibrine; and, as a consequence of all these, rather less water. The blood, in

fact, is rendered somewhat denser by inanition, though, on the whole, the contrast is by no means striking.

"The principal difference lies in the period of concretion. Is not the greater disposition to cake, in blood from a recently fed animal, dependent on that want of vital energy in the general system, which results from the activity of the digestive organs, and the more than ordinary quantity of this energy which they demand. I scarcely need refer, in illustration, to the well known languor, chilliness, and shivering which sometimes occur in man after a full meal, and to the more marked sluggishness and drowsiness which are constant in the dog. That the disposition in blood to concrete is proportionate to the debility of the system, we shall soon be able to prove and illustrate.

"The trifling excess of water in the blood of animals that have been recently fed, may be referred to the absorption from the stomach of the thinner parts of the aliment, before the more solid constituents can be elaborated by the small intestines and lacteals."

Mr. Thackrah made some experiments to ascertain whether the milky appearance sometimes observed in the serum of the blood, was dependent on digestion. The observations of Marcet and Berzelius renders it probable that the white substance is chyle not yet assimilated.

"What chemical observation leaves doubtful, physiological experiment has established. We find in dogs, that when the lacteals are fully distended, this cream-like appearance is almost always presented in the blood. Indeed, we can generally produce it at will by taking blood a certain time after a full meal. Without adducing observations which run through a course of experiments on other subjects, I give but one example.

"*Exp. CLXVII.* Four hours after a hearty meal, a dog was destroyed. The lacteals were found distended; and the blood from the jugular, portal, and caval veins presented a cream-like appearance in the serum.

"From such as this, contrasted with negative observations, we infer that *the substance mixed with serum is chyle not yet elaborated into blood.*"

Influence of Strength and Debility on the Blood.

Some experiments are detailed, made on animals bled to death, from which a comparison is drawn between different portions of blood received into vessels at intervals from the time of the animals being wounded to that of their death. From these experiments it appears—

"That in the dog, sheep, horse, and hog, the blood concretes slowly in regular proportion

to the tonic state, or that condition of the system in which the vital powers are strongest: blood received immediately before the death of the animal first assumes this change; next that which is taken at the middle period; and lastly, that which is received on the first effusion from the wound. In oxen, however, it was frequently found that coagulation took place most slowly at the middle period. At first I was at a loss to account for a circumstance so much at variance with almost every other observation. On reflection, however, I concluded that the mode by which oxen are slaughtered was the cause of this disparity; the animal being first stunned with repeated blows on the head, and afterwards bled to death by a division of the jugular vessels. The ox on falling, I conceive to be in a state resembling apoplexy, with the vital powers languid; but after the loss of a considerable quantity of blood, the nervous system is relieved of its burthen, and the constitution regains somewhat of its wonted vigour. Here, then, the powers of life are strongest at the middle period; next so is the first or comatose state; and the weakest is after great evacuations, or on the eve of death. I have further noticed, that when a comatose state is not induced, either from the inexpertness of the butcher in striking the ox, or from the animal being more than ordinarily tenacious of life, concretion commonly takes place in the same order as that which obtains in the blood of other quadrupeds. Coagulation was twice observed to commence slowly in the last-received portion of blood, but this exception being found only in the ox, may be attributed to the deranged state of the nervous system."

With regard to the exudation of serum, repeated and uniform observation has convinced the author that a state of debility causes a retardation or imperfection in this process. Blood taken from an animal in articulo mortis, never fully separates its serum, and rarely throws off even a small quantity: hence, although debility remarkably promotes concretion, it as decidedly retards and diminishes the exudation of serum; the crassamentum, therefore, retains a considerable proportion of this fluid.

The eighth chapter is on the peculiarities of the blood in different classes of animated beings. The whole subject is ably discussed; the author's own experiments, however, refer only to the following points:—

The relative quantity of Serum and Crassamentum.

"I examined," says Mr. Thackrah, "the proportion of serum to crassamentum in many experiments on various animals:

"In dogs the average appeared to be as 10 to 20 or 25
 Oxen, 10 to 16
 Horses, 10 to 13
 Sheep, the medium of some examples has been . . . 10 to 21
 While in others it was but as 10 to 8!
 Swine, 10 to 18
 Fowls, 10 to 16

"Although my experiments are far from evincing a disparity uniform in its reference to the classes of animals, yet it appears probable that a more complete examination would prove the *crassamentum* to bear a proportion to the strength and ferocity of the animal; since I never found the serum in such quantity as in the timid sheep, nor the *crassamentum* so abundant as in the predatory dog.

The Periods of Coagulation.

"In the blood of the Horse, concretion occurred in from 5 to 13 min.
 Ox, 2 to 10 —
 Sheep, hog, and rabbit, . . . ½ to 2 —
 Lamb, ½ to 1 —
 Dog, ½ to 3 —
 Duck, 1 to 2 —
 Fowls, ½ to 1½ —

"Haller observed that the blood of a mouse coagulates in a moment.

"From these observations a general inference may be drawn, that *coagulation commences sooner in small and weak animals, than in the large and strong.*"

The ninth chapter contains a very learned and judicious review of all that is known of the influence of disease on the blood. The author's own experiments relate chiefly to coagulation and the buffy coat. On the former point, his most important conclusions are—

1. That the speedy occurrence of concretion on the effusion of blood, is a sign of debility, and hence contra-indicates further depletion. The completion of coagulation does not observe the same regularity as its commencement, the perfection and duration of the process varying greatly; in a case of petechiæ hæmorrhage, related by Mr. Pretty in the London Medical and Physical Journal, the blood drawn showed no serum for eight hours, but afterwards separated a small quantity: if, however, on the division of the coagulum, at the expiration of from eight to twenty-four hours, no considerable effusion of serum ensue, and the *crassamentum* remain extraordinarily firm,

the author believes that further depletion is fully warranted.

2. That in *antonic* diseases the proportion of the *crassamentum* to the serum is increased, and, *vice versa* in those of an *atonic* kind; if, however, we find the serum in large proportion, with an extraordinarily firm *crassamentum*, we are not thence to infer debility; but if the relative quantity of serum be large, with a loose and yielding *crassamentum*, an atonic state of the system may be presumed to exist.

On the subject of the buffy coat, we find the following among other apposite observations.

"What is the buff-coat? Is it a new substance formed in the blood by disease? No: for examination proves the existence of its constituents in the blood, and shows displacement rather than creation. It is a network of fibrine enclosing serum. When pressed, the buff-coat yields a fluid which has all the properties of serum, and a substance which cannot be distinguished from fibrine. The serum drawn from the sizzly crust is stated by Dowler and Gendrin to contain a larger proportion of albumen than the serum of the rest of the blood. We found a result directly the reverse of this, viz.:—in 1000 parts of serum spontaneously exuded 134 parts of solid matter, while that of the same blood squeezed from the sizzly crust yielded but 65. The buff-coat is of greater specific gravity than the serum, a fact which I should not have noticed had it not been denied. The ratio of its solid and liquid elements, however, varies considerably. It is found in some cases to be mostly fluid; in others, it is tough and compact like leather. Yet this contrast of appearance of tenuity depends partly, I believe, on the period at which it is examined. As a specimen of the constituents of the buff-coat, I detail the following:

"Exp. CCXIII. To ascertain the proportions of solid fibrine and solid matter in serum of the buff-coat, it was carefully separated from the *crassamentum*; and after the serum had been squeezed from the fibrine, each was placed on a sand bath, and, when dry, their quantities estimated.

"Dry solid fibrine, 18
 Dry solid matter from the serum, . . 26
 Water, or loss by evaporation, . . . 56

Buff-coat. 100

"Since, then, the buff-coat is composed of fibrine retaining serum, is fibrine especially abundant in sizzly blood? Dr. Davy, from his observations, infers that there is no constant relation between the appearance of this tunic, and the proportion of fibrine; yet his tabular report shows, that in every case

but one the proportion of fibrine in buffed blood exceeded, and in most cases greatly exceeded, that which he marks as the healthy standard. From all the examinations we have made, I infer without hesitation, that buff-coated blood contains a considerably greater proportion of fibrine than healthy blood. In illustration, I may refer to the 12th section of chapter VII.

"How is the sily tunic produced? The question is not difficult of solution, if we bear in mind three circumstances: first, the increased quantity to which we have just adverted, of fibrine in sily blood; secondly, the apparent identity of the buff-coat, and the spurious membranes of disease; and thirdly, the absence of the sily crust in a perfectly healthy and unexcited state.

"From the blood are formed all the animal structures, and not less, of course, the adhesions of pleurisy than the fibres of muscle. It is obvious that provision must be made for such formations, and we find it in that great laboratory, the circulating system.

"Fibrine distributed in health in small proportions for the reparation of muscular and other structures, is increased for more extensive formations, and specially for adhesive inflammation; and from this excess of fibrine the blood drawn exhibits a fibrous crust. The greater specific gravity of the united hæmatosine and albumen, explains alike the general situation of the tunic and the prevention of a sily coat by agitation of the blood."

There is an appendix, containing some miscellaneous experiments, and detached observations, the notice of which we are obliged to omit. We regret much that our review of this admirable work, lengthened as it has been, is altogether inadequate to give a just view of the valuable matter it contains; but we must here conclude with a strong recommendation to the reader to peruse the entire volume diligently. Dr Wright has conferred a great benefit on the profession, by discharging his duty as editor in so able a manner, and thus doing justice to the memory of the lamented author. Mr. Thackrah was a young man of uncommon talents and great scientific ardour; let the College of Surgeons and the drug-vendors of Blackfriars take shame to themselves for driving him to a provincial school, by refusing to receive his certificates as a London Lecturer!

The London Medical

AND

Surgical Journal.

Saturday, February 21st, 1835.

MEDICAL FEES OUGHT TO BE REGULATED BY A LEGISLATIVE ENACTMENT.

THERE is one subject connected with medical reform which has not, we think, been sufficiently attended to, and the neglect of which by the Legislature, at the present juncture, would render all attempts at improvement abortive—we mean the regulation of professional fees.

On glancing at the past history of the medical profession in this country, it cannot but be evident that the exorbitant rate of physicians' fees has not only been a serious evil to that particular class of practitioners, but has been productive of numerous inconveniences and anomalies throughout the profession. If there be one thing more absurd and more to be lamented than another in the present constitution of the profession, it is the strange union of physician and druggist, which constitutes an English apothecary. It would be incredible if it were not known to be true, that in a civilized age and nation, the largest, best informed, and most respectable portion of a learned profession should be absolutely compelled to degrade their own character and torture the palates of their patients by a system of humbug, at once ridiculous and loathsome.

And what is the origin of all this? The high fee of the physician. Originally, the apothecary was in England, what he now is in other countries, a person whose business it was to dispense prescriptions, but who had nothing to do with medical practice; but the high fee of the physician rendered it impossible for any but the wealthy to have recourse to his assistance: hence, according to the law by which

society always creates the means of supplying, in some way or other, its more important wants, the apothecary became the medical adviser of the poor; this was an inducement to him to acquire a certain knowledge of scientific medicine, which knowledge has advanced, step by step, till, in the present day, the apothecary is, generally speaking, inferior to the physician in no respect, superior to him in more than one, and has virtually become physician to the great mass of the community. It is obvious, that if the Legislature had not been shamefully negligent of medical affairs, and the profession still more shamefully negligent of its own affairs, the connexion between science and jalap would long since have been dissolved, and the general practitioner enabled to appear in his proper character.

But it may be asked, since the education of the apothecary is now to the full as complete, and perhaps rather more expensive than that of the physician, why do the greater part of the profession persist in being apothecaries instead of becoming physicians? Answer—Because the fee of the physician is so high, that only a few of the community can afford to employ him, and it is therefore long before he can get into practice; consequently, young men who have no sufficient means independent of their profession, that is ninety-nine out of an hundred, wisely decline practising as physicians—in other words, are not enamoured of starvation.

Such are some of the evils resulting from the guinea system. Those who are in the habit of reading this Journal are aware that we regard the present organization of the profession as radically wrong; that we hold it to be an intolerable farce for a beardless Doctor to pretend to direct the practice of a man old enough to be his father, and who may be infinitely his superior in talent, information, and experience;

that we think all medical men should be general practitioners at first, and no medical man should be an apothecary at all: but if the present system of things must endure for a while (we are quite certain that it will not be permanent), then, we say, let fees be so regulated throughout the profession, as to enable young physicians to get into practice; and to enable general practitioners to exercise fairly an honourable profession, instead of being immersed in the turpitude of an execrable trade. Execrable indeed it is; the business of the *druggist* is an honest and useful business, if reputably conducted; but for a medical practitioner to seek his remuneration by pouring floods of unutterably nauseous trash into the stomachs of his patients, is an alternative which every honourable man regards with contempt, and adopts with reluctance.

One thing more we have to remark concerning fees, namely, the absurdity of making them *honorary*—in other words, payable or not at the pleasure of the patient. We cannot form the remotest idea of what those persons mean who tell us that it is conducive to the *respectability* of the profession that the payment of fees should not be obligatory; which just amounts to this—that it is for the honour of the physician that every knave who chooses may cheat him and then laugh in his face. As reasonably might it be said that it is for his honour that all thieves should be allowed to rob, or all ruffians to assault him, with impunity—the whole affair is flat nonsense.

—o—

Scarlatina.

M. Goëlis treats this disease according to the character of the fever. When the exanthematous eruption is incomplete, he washes the whole body with warm water—a treatment on which he places great reliance, and which he thinks preferable to the use of diaphoretics: these he never employs in the early part of the disease, for he considers them hurtful.

A NEW PRACTICAL FORMULARY

OF HOSPITALS, OR A

Collection of Formulae of the Civil and Military Hospitals of France, Germany, Italy, Great Britain and Ireland, &c., containing the Indication of the Doses in which simple Substances, magistral and officinal Preparations of the Codex are administered, the use of New Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M. D., and P. VAVASSEUR, M. D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M. D. &c. &c.

(Continued from p. 86.)

Collyroire Alcaline. H. Militaires.

Rx. Potassæ subcarbonatis, 3j;
Mellis, 3ij ss;

Tere in mortario vitreo.

Red Collyrium. H. of Montp.

Rx. Potassæ subcarbon. gr. xxij;
Camphoræ, gr. x;
Aque destillat., 3ij.

In balneo aren. horis xxiv macera;
dein cola et adde,

Tincturæ aloes, in xxiv.

Used in opacities, or specks on the cornea.

Alkaline Pediluvium. H. St. Ant.

Rx. Potassæ subcarbonatis, 3viij;
Aque, q. s.

Ut fiat pediluvium.

Employed in the same cases as the mustard pediluvium.

Lotion used in Pernio. H. of Italy.

Rx. Potassæ subcarbonatis, 3ij;
Aque rosæ, Oij.

Solve.

Compresses dipped in this lotion should be applied to the affected part.

Alkaline Liniment. H. of Germ.

Rx. Potassæ subcarbonatis, 3ij;
Olei amygdalæ, 3iv;
Vitelli ovi, No. ij.

Fiat linimentum.

M. Plenck recommends this liniment in the treatment of chaps and excoriations.

Antipsoric Ointment. H. of Italy.

Rx. Potassæ Subcarbonatis, 3j;
Sulphuris præcipitati, 3ij;
Adipis, 3iv.

Fiat unguentum.

Quater in die, applicandum, partibus affectis.

BICARBONATE OF POTASSA.

It possesses the same action as the subcarbonate, without the caustic quality of the latter; consequently it is preferable to that medicine in many cases where it is necessary to administer it internally; nevertheless, it is not much used.

INTERNALLY. The same doses as the subcarbonate.

Eau méphitique Alcaline.

Rx. Potassæ bicarbonatis, 3ij;
Aque acido carbonico saturatæ,
Oij.

Solve.

3viij, ad xij. quotidie sumendæ.

As a tonic, diuretic, and antacid. It is also much used in calculous affections.

[D] dissolved in 3viij of water, and mixed with 3iv of lemon juice, forms an effervescing draught. T.]

SUBCARBONATE OF SODA.

It possesses the same medicinal properties as the subcarbonate of potassa; but, as it is not caustic, it is more frequently used. Preference is given to it in cases of acidity of the stomach, hooping cough, &c. Some practitioners use it in bronchocele.

Subst. incomp. The same as for the preceding substances.

INTERNALLY. As a stomachic and antacid, from gr. x—3ss in pills, with some bitter extract. As a diuretic, from gr. x—xx, dissolved in Oj of water.

Pills of the Subcarbonate of Soda. H. of Eng.

Rx. Sodæ subcarbonatis, 3liij;
Saponis duri, 3j;
Olei Carui, gut. x;
Aque, q. s.

Divide in pilulas, gr. ij, quarum capiat j—liij bis vel ter in die.

Absorbent Pills. H. of America.

Rx. Sodæ subcarbon.;
Pulveris rhei;
Extracti gentianæ, aa 3j;
Hydrarg. submur., gr. iij.

Divide in pilulas xx, quarum capiat unam mane vespereque.

[In acidities of the stomach, calculus, and other affections of the genito-urinary organs, when the urine is depositing lithic acid, in the ardor urinæ caused by gonorrhœa and strangury, induced by blisters. In these cases, 3j—iv, may be given daily in barley water, whey, linseed tea, &c. I have repeatedly employed it with success. It must not be continued when the urine deposits a whitish sediment (the phosphates). The soda powders, consisting of carbonate of soda, and tartaric acid, form artificial soda water, of which two or three glasses may be taken daily. The tartrate of soda formed by the union of the ingredients, often acts on the bowels as a mild aperient. T.]

Stomachic Boluses. (Swedhur.)

Rx. Sodæ subcarbonatis, gr. xij;
Cannellæ pulveris, 3iv;
Syrupi cinchonæ, q. s.

In bolos tres divide, quotidie sumenda.

Antinephritic Potion. H. of Lyons.

Rx. Seminum lini,
Adianthi, āā manip. s;
Aquæ fontanæ, Oj.

Coque cola, et adde,

Sodæ subcarbon., ℥j.

Dosis, cyathus sæpe in die.

[Linseed tea is an old remedy in coughs, gravel, and urinary diseases, gonorrhœa, &c. T.]

Lithontriptic Potion. H. of America.

Rx. Sodæ subcarbon., 3j;
Infusi quassiae, ℥iv;
Tincturæ calumbæ, 3j.

Dosis, cochleare amplum, quater de die.

Absorbent Potion. (Swediaur.)

Rx. Sodæ subcarbon., ℥ij;
Rhei pulveris, 3ij;
Syrupi simplicis, 3j;
Aquæ menthæ pip., 3viij.

Sit mistura, cujus capiat cochleare amplum ter quaterve in die.

Antiscrofulous Potion. Hotel Dieu.

Rx. Sodæ subcarbon., 3ss;
Tinct. gentianæ, 3j.

Fiat haustus, cujus sumat cochl. mag. ter quotidie.

The subcarbonate of soda is sometimes substituted for the soda.

EXTERNALLY in frictions. 3j to 3j of hog's lard.

In injections. 3j to ℥j, of a proper vehicle.

Lithontriptic Injection. H. of Montepelier.

Rx. Sodæ subcarbon, 3j;
Saponis, 3ij;
Aquæ, 3xij.

Misce.

Recommended for dissolving the calculi of uric acid.

Pommade used in Prurigo, called Pommade No. 4. H. St. L.

Rx. Sodæ subcarbon., 3ij;
Extracti opii, gr. x;
Calcis, 3j;
Adipis, 3ij.

Misce.

Employed with advantage in different kinds of prurigo.

The *Pommade Alcaline* of the H. des Ven, differs from the preceding one in not containing the lime, for which is substituted the subcarbonate of soda, and 3j of the compound wine of opium to 3j of lard.

BICARBONATE OF SODA.

The bicarbonate of soda possesses the same properties as the bicarbonate of potass, but is more efficacious. It is much used in calculous affections, and in various cases of difficult digestion, especially in patients subject to gout and gravel.

INTERNALLY, as a diuretic, gr. xij—3ss in an aqueous vehicle.

As a stomachic, gr ij—iv, in pastiles.

Alcaline Troches. (Magendie).

Rx. Bicarbon. sodæ, 3j;
Sacchari., 3ij;
Mucilaginis astragali, q. s.;
Olei, menthæ piperitæ gutt., iij.

Divide in trochiscos Lxxij asquibus, capiat ij vel iv statim, ante vel post prandium.

They should be kept in a bottle well corked. The oil of peppermint may be replaced by the balsam of tolu.

SQUILLS.

In large doses this medicine is an irritant, inducing nausea, &c.; in smaller ones, it is diuretic, and stimulates the mucous membrane of the bronchiæ. It is principally used as a diuretic and expectorant, sometimes as a general stimulant but in all cases is united with some other ingredient, such as opium, calomel, &c.

INTERNALLY. Powder, grs.—i—x in pills.

Pilules scillitiques. P. Gr. ij—vj, twice or thrice a day.

Poudre incisive. P. G. x—xx.

Tincture. P. Gutt. x—xxx in an emulsive or mucilaginous potion.

Vin scillitique. P. 3ss to 3j, in a proper vehicle.

Vinagre scillitique. P. 3ss—3j.

Oxymel scillitique. P. 3ss—3j, in a potion or proper vehicle.

Mel. scillitique. P. The same doses.

Expectorant Powder. Hot. D.

Rx. Scillæ, gr. xij;
Ipecacuanhæ, ℥j.

Divide in chartulas iv, quarum sumat unam tertiâ quaque horâ.

In chronic pulmonary catarrh, towards the end of pneumonia, &c.

Powder of Squills. H. of Eng.

Rx. Scillæ, 3j;
Potassæ tartratis 3ix.

Fiat pulvis, gr. x—xxx, bis vel ter in die sumenda.

As a diuretic, ten grains of this powder contains iij of squills.

Diuretic Powder. H. of Eng.

Rx. Scillæ, ℥j;
Opii, gr. iv;
Cinnamomi, 3j.

Divide in chartulas, viij, quarum sumat duas quotidie.

In dropsy. Each packet contains gr. iij of squills.

Compound Powder of Squills. H. Germ.

Rx. Scillæ, gr. xv;
Iridis florentiæ,
Glycyrrhizæ, ā ā gr. x;
Lactis cum saccharo, ℥ij;
Olei anisi, gutt. iij.

Fiat pulvis in chartulas tres distribuendus, quarum una mane nocteque sumenda.

In the same cases as the above.

Each packet contains gr. iij of squills.

(To be continued).

VICARIOUS LACTATION.

To the Editor of the Original London Medical and Surgical Journal.

SIR—Not having met with a similar case to the following, during nearly twenty years' practice in the metropolis, I cannot but consider it one of exceedingly rare occurrence, and such as you may probably deem worthy of professional record. It is that of a woman who during the latter months of utero-gestation, and at the period of lactation, has the axillary gland under each arm much enlarged, and secreting a profusion of milk, pouring it forth simultaneously, and probably sympathetically, every time she applies her infant to the natural source; the gland, with the accompanying distended integument, forms a tumour of the size and shape of an ordinary sized tea-cup inverted, which yields upon lateral compression a copious discharge of milk, passing through the cuticular pores; by applying the breast-pump, I extracted a considerable quantity of fluid, having the apparent character of milk, separating into serum and curd upon the addition of acetic acid. I should feel much pleasure in submitting the case to your investigation, and will direct the subject of it to call at your residence, if you wish it, at any time you may please to appoint; and remain, Sir,

Your's, respectfully,

JOHN LANGLEY.

36, Tottenham Street, Fitzroy Square.
Feb. 11th, 1835.

—o—

Foreign Medicine.

Blue Fever of Children (*Febris Cærulea*).

THE disease thus named by M. Goëlis is an affection *sui generis* not hitherto described; it is not to be confounded with the *morbus cæruleus* caused by diseased heart. It is only seen in children from four to twelve months old, and most commonly among the lower classes, who, together with the ingestion of coarse farinaceous food, are subject to the mischiefs of damp unwholesome habitations. The disease always comes on by paroxysms, the children becoming suddenly blue, the respiration difficult, the pulse small, hard, and spasmodic. The paroxysm lasts for some time, disappears and returns: but the intervals daily become less, and the paroxysms finally coalesce. The skin is frequently covered with a viscid sweat, and death takes place suddenly. On dissection, the blood vessels are found greatly congested. Apart from the febrile state which accompanies the attacks, the disease presents all the characters of a nervous disorder; and the remedies that have succeeded the best with M. Goëlis are the succinate of ammonia, and other antispasmodics, combined with mucilaginous medicines.

Together with these internal remedies, warm alkaline baths should be used. When

we have succeeded in overcoming the spasm, a purgative of calomel or a mixture of rhubarb and magnesia should be administered.

Children are, besides, subject to a peculiar *chronic sweat*, which differs from the sweating sickness in possessing no febrile characteristics. In these cases the skin becomes bluish, and, as it were, transparent. This state can very well be combated, according to M. Goëlis, by the administration of a slight infusion of bark with milk, and by frictions with oil of sweet almonds repeated several times in the day.—From the Work of M. Goëlis quoted in our last.

Facial Carbuncle—Cauterization.

M. Lisfranc shewed the Academy de Médecine a man who had been affected with carbuncle. The disease had invaded both eye-lids of the right eye, and had already caused the elastic tumefaction of the thoracic parietes, which is generally observed when the disease is somewhat advanced. M. Lisfranc used the actual cautery: he not only cauterized the eschar after having incised it, but also produced a second burn extending at least three inches beyond the dead parts. An inflammatory circle was formed; the gangrenous parts sloughed away, and the ulcer beneath was found to occupy the whole extent of the anterior surface of the eye-lids, the skin of which was entirely destroyed: the ulcer extended an inch above the eye-brow, two inches below the orbit, and an inch and a half towards the temple.

In order to keep the eye-lids in position during the cicatrization of the ulcer, and avoid their eversion, M. Lisfranc applied two pieces of plaster, which, extending from the temple over the forehead and root of the nose, were moulded to the orbit, and left a space between them corresponding to the centre of that cavity. Over these he placed a large lint tampon and compresses, and maintained the whole with the monocle bandage. The wound healed, and no eversion of the eye-lids took place.—*Gaz. Med.*, Feb. 7, 1835.

[In our next we shall give an account of a very interesting operation on the lower jaw, performed by M. Lisfranc].

Hospital Reports.

ST. GEORGE'S HOSPITAL.

—o—

Rhinoplastic Operation.

At page {26 of our present volume, will be found a part of the report of the progress of the above operation, which, by some mistake of the printer's, was inserted without that of the operation itself, which is as follows:—

A man had for some months been an in-patient of the hospital, labouring under syphilitic caries of the nasal and frontal bones, which had given rise to a large open-

ing into the frontal sinus and upper chamber of the nose. This opening occupied the root of the nose, being, however, situated rather to the right side, so as to encroach somewhat upon the lachrymal apparatus situated at the inner canthus of the eye. The rhinoplastic operation was decided upon as that which alone gave any chance of restoring the organ. Mr. Keate, under whose care the patient was, commenced by refreshing the edges of the fistulous opening with a bistoury, in doing which a little bleeding was occasioned, more particularly from the angular artery. A card-board pattern of the opening was now employed to mark out the flap, which was taken from the forehead over the left eyebrow, in such a manner that its internal and inferior angle was made to correspond with the internal and superior angle of the opening. The flap was next raised and dissected off, in doing which some branches of the supra-orbital artery were divided, which bled somewhat profusely; but Sir B. Brodie, who assisted at the operation, restrained the hæmorrhage by making pressure upon the vessel, until he had an opportunity of entirely commanding it by the application of a ligature. The flap of skin, which was merely connected by a narrow isthmus to the surrounding integuments, was now twisted round and adjusted over the opening, and their respective edges brought into close apposition with each other. These were retained in this situation by stitches of suture, applied at almost every point of the circumference, and amounting to ten or twelve in number. Strips of adhesive plaister were also applied, so as to still more favour adhesion taking place; pressure was also made with pledgets of lint all round, except at the isthmus of connecting skin, which was carefully protected from all pressure. The size of the large gap in the skin over the left eyebrow, from whence the flap had been taken, was considerably diminished by drawing the edges of the skin towards each other by means of long strips of adhesive plaister. The dressings were kept in situ by means of a roller carefully applied, and the patient was then removed to the ward.

WESTMINSTER HOSPITAL.

Stone in the Bladder of a Female, of immense size—Lithotomy, &c.

(Case of *Mary Kean*—continued from vol. 6, page 540.)

Nov. 22nd, 1834. Not so well as at last report; has been in great pain, and suffered from considerable constitutional irritation. Opium, in the form of 3ss doses of the liquor opii sedativus during the day, and in that of 1 grain of the acetate of morphia in an enema at bed-time, failed in affording relief to the pain. During the last two or

three days diarrhœa has been present, for which she has had the croceous mixture.

24th. Mr. Guthrie, the other day, consulted Mr. White upon the case, and it is agreed to commence dilating the urethra as soon as possible. He prescribed the following mixture for the diarrhœa, which has yielded under its use..

Rx. Vini ferri, ʒvj;

Liquor. opii sedativ., 3j;

Infus. cascariillæ, 3vij., M. ft. mist.

Capt. cochlear. iij, 4tis horis.

26th. Better than at last report, although she continues to complain of pain in the hypogastric region.

Dec. 20th. Considerably better than at last report, both as respects the constitutional and local symptoms. She has commenced the employment of the sponge tent in order to dilate the urethra gradually; it is found necessary to be very cautious in its employment, as any sudden increase in the dilatation, is found to occasion great irritation.

Jan. 4th. She has been prevented from using the sponge tent lately, in consequence of constitutional disturbance.

Jan. 28th. Much the same as at last report. No further progress has been made towards effecting the complete dilatation of the urethra; as fast as a little step is gained, the patient being obliged to omit the use of the sponge on account of its inducing such excessive irritation. She has, however, again commenced its employment.

Feb. 8th. A consultation on the case, between Mr. Guthrie and Mr. White took place yesterday, when Mr. Guthrie found by examination per vaginam, that the calculus was now of immense size, of an irregular, flattened, ovoid shape, having increased materially since the attempted removal of it about nine months ago. It was agreed that the operation should take place to-day; and as the patient refused to allow it to be performed in the theatre, before the pupils, it was done in a private room. Mr. Guthrie was assisted in the operation by Mr. White, Mr. Thomson, Mr. Hancock, and Mr. Charles Guthrie. Mr. Weiss was present, in order to supply any deficiency in the instruments. The patient being placed upon Heurteloup's bed, Mr. Guthrie commenced by enlarging the already dilated urethra, which he did by dividing it for the space of about half an inch in a direction vertically upwards, towards the symphysis pubis. The common two-branched dilator was now introduced, with the view of still further enlarging the passage, and this was repeated several times, until the fore-finger was allowed ready ingress into the bladder. The calculus was in this way readily detected close against the opening of the urethra, and surrounded by the firm embrace of the bladder. A

very strong forceps, with a screw adapted to the handles, had been purposely constructed by Mr. Weiss, with the view of grasping the calculus between the blades and breaking it by the force of the screw. This was now introduced, but it was found quite impracticable to separate the blades of the instrument sufficiently to admit of the stone being grasped, and after several ineffectual attempts, it was found necessary to relinquish them, a little of the outer phosphatic crust of the calculus having been removed by them. It was now suggested that by introducing one blade at a time, passing one above and the other below the calculus, the seizure of it might be effected. The screw was then removed from a pair of strong common lithotomy forceps, the two blades of which were introduced in this way, but without effecting anything beyond breaking a very small piece of the calculus, although several attempts were made. Recourse was now had to the "screw lithotrite," lately introduced in an improved form by Mr. Weiss. The lower branch of this instrument was first introduced, and the curved extremity being got beyond the stone, this was readily drawn forwards by it, and the upper branch being now placed in the groove of the other, and its point protected by a director, was pushed through the urethra, and in this way Mr. Guthrie succeeded in grasping securely the calculus. The force of the screw was now employed, and by this means a considerable portion was broken off the main body of the calculus, which was extracted by the small forceps. From the difficulty which was experienced in the introduction of this instrument, (as may be readily conceived, when it is recollected that it is adapted only for introduction through the urethra in a united form), recurrence was had to various forms of forceps, as well as to those before alluded to. One of these was broken in the bladder, and the piece extracted. As, however, it was found perfectly impossible to effect anything with these, they were finally laid aside and the screw-lithotrite again had recourse to. It is unnecessary further to detail the precise steps of the operation, the peculiar difficulties of which have already been made sufficiently apparent; but it may be briefly stated, that by the repeated application of this instrument, the calculus, though often missed, was several times seized and broken, and the portions afterwards extracted with the smaller forceps. Three or four of the portions thus brought away were of very considerable size, one of them having a diameter of at least an inch and a half, and being of a cuboid form.

Some blood was lost from the urethra during the operation, which occupied about three hours, the further prolongation being considered improper, as the patient was becoming somewhat exhausted. She was therefore removed immediately to a bed in

a separate room. The pulse was 144, small, but not particularly feeble. She was ordered to have one grain of acetate of morphia.

The fragments extracted amounted in weight to four ounces! and it was thought that almost the half of the stone still remained in the bladder. With respect to the nature of the calculus, it was chiefly composed of lithic acid of a rather deep fawn-colour, having a rather beautiful crystalline arrangement of its particles, which also were very distinctly deposited in regular strata. A nucleus of the size of a horse-bean, of a very hard character, and a dark brown colour externally, but greyish within, and which appeared to consist of oxalate of lime, was also extracted. The calculus had also a very delicate cortex of a white colour, and evidently consisting of the phosphates.

9th. (the day after the operation). This morning is better every way than could have been expected. She has had some rest during the night, and is evidently recovering from the state of exhaustion. Mr. Guthrie says that every thing is going on just as well as could be wished.

14th. At the conclusion of a clinical lecture to-day, Mr. Guthrie gave a hasty sketch of the case to the pupils, and informed them that the patient was going on very well, and that he hoped in the course of three weeks to be able to remove the remainder of the calculus. He attributed the so-far successful result to the cautious employment of the various instruments; and so long as this was attended to, he considered that operations might frequently be with propriety protracted beyond the canonical time of an hour.

Necrosis of the Inferior Maxilla—Division of the Hypoglossal Nerve.

(Case of *Samuel Brinnigan* continued).

14th. The wound in the face is going on very favourably; it is filling up with the healthy granulations, and discharges a healthy pus. The surrounding erythema is likewise evidently diminished.

In our last report we alluded to an impediment in the speech, which the patient attributed to the ball's passing through the mouth, but which we then, hastily indeed, and on anatomical grounds, and without having had an opportunity of examining the tongue in relation to this point, referred to an injury of the mouth, or hypoglossal nerve inflicted by the ball in its trajectory across the summit of the neck. To-day, however, we found that this conjecture was fully verified, for Mr. Guthrie drew the particular attention of the pupils to the fact of there being a complete paralysis of the left half of the tongue; the muscles of the right side, retaining their power, draw it, when protruded, round the right angle of

the month, in a very grotesque manner. Neither the sense of taste nor that of touch is in the least affected. We must express our dissent from an opinion which we heard expressed in the ward by no mean authority, that the way to restore the equilibrium of the organ would be to divide the nerve of the opposite side, for as not a single anterior or motor filament of the fifth nerve (we speak from actual dissection) reaches the tongue, such a proceeding would necessarily produce a total paralysis of the organ.

BOOKS.

The Principles of Physiology applied to the Preservation of Health, and to the Improvement of Physical and Mental Education. By Andrew Coomb, M.D., Fellow of the Royal College of Physicians of Edinburgh. Third Edition, revised and enlarged. Edinburgh, 1835. 12mo. MacLachlan and Stewart.

The third edition, in eleven months, of a work entitled to a place in every family and medical library.

The London Anatomist, or a System of Anatomy, Physiology, and Surgery, combined by G. D. Dermott, Lecturer on Anatomy, Physiology, and Surgery. London. 1835. No. I. pp. 94. Price 2s.!

An exceedingly instructive and a very cheap publication. It is arranged in accordance with science, and is a valuable vademecum to the student and practitioner.

CORRESPONDENTS.

W. H. J.—Our correspondent is in error. He surely cannot expect two Courses of Lectures on the same subject, in the same Journal. Reports of Societies are little

more than advertisements of certain individuals. The Clinical Lectures alluded to will be continued.

Eblanensis.—We expected every opposition; but certainly not that our Journal, forwarded regularly for six months, should be withheld from our personal friend. We shall meet our opponents at Philippl.

Dr. Corrigan's Lectures will be published immediately.

A., Senex, &c.—Buffoonery.

J.—The Index and Title page will be published next week. Our correspondents know little of the labour and trouble of index-making: we should advise some one of them to amuse himself by preparing an alphabetical index of any three numbers, and then he will be enabled to judge of the time it takes to prepare one for twenty-six numbers.

A Liverpool Friend.—Many thanks for the communication.

An Hospital Student.—The complaint is just, but neither the governors, public, nor students, can reasonably expect medical officers of hospitals, who give their services gratuitously, to sacrifice their personal interests. If they were remunerated for their services, then, and not until then, ought they to be punctual in their attendance. Surely an hospital or dispensary medical officer cannot be expected to lose a private patient in the upper ranks of society, and injure his family, for nothing.

Crito.—Certainly—the three lectures are as puerile as could be found. We say, "Go on and prosper."

LECTURES

ON

MEDICAL JURISPRUDENCE,

DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,

At the University of London; Session 1834-35.

LECTURE XIX.

Disqualification for Military or Civil Service.

GENTLEMEN—*Hæmorrhages* are feigned, particularly hæmoptysis, by sucking blood from the cheeks and gums; but this imposition is easily detected by the state of the pulse, which in real hæmoptysis is small, irritable, and quick, whilst it remains natural in the feigned disease. In the feigned disease, also, there is no dyspnoea, and the appearance of the sputa confirms the suspicion; and, when the mouth and fauces are examined, the deception is at once discovered. The stethoscope, also, now affords us the means of readily detecting real from feigned pulmonary diseases.

Hæmatemesis is frequently feigned by soldiers and negro slaves. It is effected by swallowing real blood, and afterwards disgorging it by the aid of an emetic. Sauvage mentions the case of a girl who wished to escape from a convent, and for this purpose feigned hæmatemesis. She brought up several pounds of blood in the presence of several physicians, on several successive days. The imposition was suspected; and she at length acknowledged that she had swallowed bullock's blood always before the visit. The absence of the symptoms which always accompany the vomiting of blood in hæmatemesis readily detects this imposition; and the suspicion may be verified by watching the patient, so as to prevent the means of keeping up the simulation from being obtained.

The power, also, of imitating *tympanites* was well exemplified in a case under my own observation.

The extent to which the proofs of feigned diseases might be carried would far exceed the limits of a lecture; I will therefore conclude by noticing that no disease is more easily feigned, or more difficult of detection,

than *insanity*; and we have instances of its being feigned in all ages, both for private and public purposes; but particularly to defeat the purposes of justice. It is but proper to say, that a high authority on this subject denies the facility of simulating insanity: "To sustain," says Dr. Haslam, "the character of a paroxysm of active insanity, would require a continuity of exertion beyond the power of a sane person; the impostors cannot keep up the deception when they suppose themselves alone and unwatched; the assumed malady then disappears, and the imposture is recommenced when they are in the society of others. They are likewise unable to prevent sleep. If they endeavour," continues Dr. Haslam, "the passive forms of this malady, which is an attempt of considerable difficulty, they are deficient in the presiding principle, the ruling delusion, the unfounded aversions, and causeless attachments which characterise insanity—they are unable to mimic the solemn dignity of systematic madness, nor recur to those associations which mark this disorder; and they will want the peculiarity of look which so strongly impresses an experienced observer."

With the highest respect for the authority of one so conversant with the symptoms of insanity as Dr. Haslam, I must nevertheless differ from him as to the possibility of feigning insanity, so as to deceive experienced practitioners in the same line of profession which Dr. Haslam practises. An instance of this has come within my own knowledge. (Here the lecturer related a case which occurred at Glasgow).

The detection of feigned madness, as you may perceive from the story which I have just told you, is frequently a matter of great judicial importance, involving the dearest interests of individuals and families, and not unfrequently the peace of society. But it is the extremes of madness only which can be feigned—furious mania, and idiocy. In the former the impostor generally fails in the watchfulness which always accompanies furious delirium; the very means he adopts to impose on others unveils his knavery, by the exhaustion it

causes, and sleep overpowers him; whereas the real furious maniac will be many days, even weeks without sleep. Idiocy is more easily feigned. "We knew," says one of the writers of the article Feigned Diseases, in the Cyclopaedia of Medicine, "an instance of a young player who was drafted into the army, and acted the part of an idiot so effectually that he procured his discharge. The following may be regarded as the guides most likely to lead you to a correct diagnosis in your examination of a case of supposed feigned insanity: in detailing them it is impossible to avoid anticipating the view of insanity as an object of medical jurisprudence, which is soon to occupy our attention.

1. In feigning madness, pretenders generally outstrip madness; they out-Herod Herod, exhibiting themselves and the disease which they are simulating, in the most violent and disgusting points of view; and, by this excess of colouring, and caricature outline, they are readily detected.

2. Real madmen, in their lucid intervals, are anxious to conceal their state, and if questioned regarding it, reply that they are not mad, nor ever have been so: feigned madmen, in the pretended lucid intervals, never desire to conceal the condition they desire to imitate.

3. The sleeping hours of the feigned madman must be closely watched, for he is unequal to the degree of watchfulness which is a constant attendant on real insanity.

4. The medical practitioner should visit the patient at all hours, but more particularly in the morning, before he rises from bed; for there is a peculiar animal odour exhaled from the bodies of maniacs, which if once smelt, can never be mistaken, and never present but in cases of real insanity.

5. The pulse, also, forms a source of diagnosis: it is quicker in all the grades of madness than in health; but this admits of some fallacy.

6. Emetics scarcely act on the insane: if a common dose, therefore, of tartar emetic produce a full effect, deception may be suspected. If the madness attempted to be feigned, is melancholy madness, a drastic purgative may be administered, as melancholy maniacs are very insensible to the influence of drastic purgatives.

7. If idiocy be the kind of insanity feigned, something may be deduced by comparing their pusillanimity and submissiveness, their memory and conception of ideas, with those of a sane person.

8. In ordinary madness, there is no hesitation and reflection observed in discourse; the ideas succeed each other with the greatest rapidity, and the most incoherent wandering. If punishment be threatened, the real madman scarcely heeds it, being so fully occupied with the phantasms of his imagination, as to be insensible either to

hope or fear: but real punishment has a powerful effect on a madman; the feigned madman dreads the threatening, but again repeats his pretended madness. I cannot avoid noticing to you a very admirable illustration of the effect of punishment in a real madman, by Cervantes, in his preface to *Don Quixotte*. (Here the Lecturer related the story of the madman who carried a stone on his head).

9. The most certain test is the whirling chair, which is placed upon a spindle, so as to revolve on its own axis, and is whirled with the rapidity of a fly-jack, by aid of a wheel and crank; it causes nausea to syncope, so that, as few men can act a part after such discipline, the impostor generally confesses the deceit. But persons not only feign diseases, but actually maim themselves to excite pity. The common law says, "that any person maiming himself, to have a specious pretence for asking charity, or to prevent his being impressed as a sailor, or enlisted as a soldier, may be indicted, and on conviction, fined and imprisoned. (2 East, p. 822).

Such are the modes of detecting feigned diseases, which I have treated under the head of military disqualifications, rather than elsewhere, as they are most generally attempted by soldiers and sailors. Although I believe that officers of even great experience in the tricks of soldiers, have often been deceived by them, yet, you must recollect that it is the business of a surgeon to a regiment, or a physician to the forces, to know thoroughly the symptoms of disease; and that the indulgence which should be readily granted to the officer, cannot be extended to the medical man. In the case of officers feigning illness, many difficulties present themselves: some of the best, and a few of the worst feelings of our nature, come into play, and interfere with the performance of strict impartiality: but one line of duty only should direct you—that dictated by truth and honour.

With regard to disqualifications to serve on juries, little more need be said than to mention the diseases which unfit an individual to sit long in court, and to undergo the fatigue incident to the duty of a jurymen. These are what are mentioned in your syllabus—severe asthma—epilepsy—consumption—aneurism—stone in the bladder—vertiginous affections, and infirmity from age. The propriety of granting certificates of inability to serve must be obvious to every one who is acquainted with the nature of the duty of a jurymen, not only as refers to the fatigue incident to every trial, but also on account of the confinement which may occur after the trial. "By the law of England, a jury, after their evidence given upon the issue, ought to be kept together in some convenient place, without meat or drink, fire or candle, and without speech with any, unless it be the bailiff, and with him only if they

be agreed." (Hargrave's Coke on Littleton, l. 3, c. 5, sect. 366, p. 227 b). The infirmity of age is too little attended to. I had an opportunity of witnessing the fatal effects of a certificate being refused by a medical man, on this account, which obliged the old gentleman to attend as a jurymen; and, from false delicacy, having retained his urine for two hours longer than usual, a disease was brought on which terminated in his death. But this is a rare case; and, in general, practitioners, instead of refusing, are too ready to grant certificates, on the loosest investigation of the case.

When a certificate is required, whether to exempt from military service, from civil service as a jurymen, or as a witness, or to arrest execution in criminal cases, the same honour which should guide an upright and high-minded man in the ordinary transactions of life, should regulate the conduct of the medical practitioner in this case, in which his skill and the correctness of his testimony are to decide. In cases of military service, he must look at every state of disease with the eye of suspicion; must investigate minutely the symptoms under which the applicant for exemption is said to labour; he must inquire into the circumstances of their accession, progress, order of succession, intensity and duration. If this investigation be conducted with skill, and if his examination be frequently repeated, few of the wiles, even of *old* impostors, will escape the eye of experience, and deceptions will rarely fail of being unmasked. But, after all, the task is extremely difficult to execute well; and, although some disgrace must always attach to a practitioner who permits himself to be deceived by a feigned disease, yet it has occasionally happened to the most experienced and cautious; and I cannot agree in the opinion of Dr. Beck—"that nothing can be more disgraceful to a surgeon." In granting certificates to exempt from service on juries, or to appear as

witnesses, the same and even more caution is requisite. You should always object to granting certificates in such cases to individuals who are not your ordinary patients; for the very act of a person requiring a certificate from a stranger to his ordinary habits and health, throws some suspicion upon the request. But when we have an opportunity of knowing the state of the person requiring the certificate, although he be not at the moment labouring under acute disease, yet, if he be liable to attacks which can only be warded off by calm, and freedom from fatigue and anxiety, it is our duty to grant a certificate, and to stand between every effort to enforce duties, which are not indispensable, upon the subjects of such maladies. With regard to certificates to excuse witnesses from appearing in Court, as more freedom is permitted to them in every respect, than to jurymen, less tenderness is requisite towards their ordinary ailments; and unless a witness be actually confined to bed, or labouring under some acute disease, he can hardly be regarded as excusable in absenting himself from Court, in cases the adjudication of which may materially depend on his evidence. The acuteness of counsel generally discover frivolous certificates; and, in a trial which occurred a few years ago, the honour of the profession was not raised by the discovery of a certificate of this kind having, *inadvertently*, been given upon very slight grounds by a respectable practitioner in the neighbourhood of the metropolis. In every case, your certificate should be granted only upon such grounds as you can always be prepared to defend, should the statements in it be called in question.

With respect to criminal cases, it is impossible to suggest specific rules applicable to every case. Humanity, where it does not oppose justice, or infringe upon truth, ought to be our guide.

LECTURES

ON THE

INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE XII.

Decomposition of Organized Matters—Classification of Functions.

DURING all the above, and other similar decompositions of organic matters, myriads of minute plants, called mould, &c., and of animalcules, according to the nature of the matters so decomposed, usually manifest themselves. This phenomenon was, till lately, in general attributed to the development, in the matters undergoing decomposition, of minute germs, which were presumed to be universally disseminated, but to become developed only when they met with a congenial soil, such as that afforded by the products of decomposition.

tion (a). Of late, however, this hypothesis has been in a great measure superseded by another, which ascribes these plants and animalcules to the retention, by a portion of the extractive, sodo-albumen, gelatin, and so forth—the globules of which, it must be remembered, are regarded as organic elements or molecules—of their supposed aptitude for life, so that certain globules of these matters take on, more or fewer of them together, the form of distinct organized beings (b). It has been already mentioned that the highest tribes of plants and animals have been supposed to differ from the lowest, as well as the perfect plant and animal of every tribe from its earliest germ, only in the circumstance of more organic molecules—the primary as well as continual source of which is the aliment—entering into their composition; and it is hence easy to conceive that as a progressive amalgamation, as it were, of these molecules might, at the creation, form in succession each higher species of organized beings from those below it, as well as, during the development of each individual in its generation, carry it successively through all the inferior types till it finished with its own; so a separation of the same molecules might, either as passed off with the excretions, or on the decomposition of each individual of a higher species, again give rise to innumerable individuals of a lower grade, the same being ready subsequently to contribute, either by receiving into themselves new organic molecules or furnishing the same to other organized beings, to the formation again of any mode of organized existence superior to themselves (c). And that such is the origin of the mould and animalcules in question has been inferred from the globules of such organic matters having been observed to be from the first in constant agitation; and from such moulds and animalcules having been detected in infusions of organic substances, during their decomposition, even when these substances have been previously exposed to a heat sufficient, it is presumed, to destroy all germs, when only distilled water has been used, and when the infusion has been kept constantly in vacuo (d). But that the doctrine of the perpetual transmigration of any supposed organic molecules, whether well or ill-founded, cannot apply to the globules of extractive, sodo-albumen, gelatin, &c., which are pretty certainly not identical with them, and have not the aptitude for life alluded to, is obvious; and it is equally so that it cannot be true of the really organic molecules, if we believe that it is into extractive, sodo-albumen, and so forth, that these molecules, or the organized tissues composed of them, are, on the cessation of their vitality, converted. It is a fair objection likewise to the hypothesis in question, or rather to an immediate corollary from it, namely, that the whole of organized nature consists at all times, and has at all times consisted of the same definite number of organic molecules (e)—that a very considerable pro-

(a) Harvey—the author of the celebrated axiom, “*Omnia ab ovo*”—Leeuwenhoek, Redi, Swammerdam, Spallanzani, Bonnet, Linnæus, Ehrenberg, &c.

(b) Turberville, Needham, Buffon, Lamarck, G. R. Treviranus, Tiedemann, H. M. Edwards, Dutrochet, Dumas and Prevost, &c. This doctrine, although allied to the ancient hypothesis of “*Equivocal Generation*,” is not identical with it; since, while by the latter certain matters were supposed to be vivified *de novo* by the heat evolved during putrefaction, and thus to assume the form of distinct animalcules, by the latter these matters are believed to be possessed of innate vitality, and to acquire newly each an independent existence by separation.

(c) *Haud igitur penitus pereunt quæquomque videntur,*

*Quando aliud ex alio reficit Natura;
nec ullam*

Rem gigni patitur, nisi morte adjecta aliena.

Well might the ancients say, if this be true, Death is the mother of life—*Nascimur ad mortem, morimur ad vitam*—since what is called the death of a tree or a man is nothing more than the separation of a vast bag of mould or animalcules, which, as Dr. Prichard expresses it, “had been tied up together, and obliged to subsist within one

bark or skin,” into fragments, which may either coalesce together into some higher tribes, indiscriminately, of plants or animals, “*De même,*” says Edwards, “*que les sels affectent en cristallisant,*” or go to form a future tree of the same kind, or a future man, by entering with their food. “Here’s fine revolution, an we had the trick to see it.” It had been long known that “we fat all creatures else to fat us, and we fat ourselves for maggots”—it had been long known that “a man may fish with a worm that hath ate of a king; and eat of the fish that hath fed of that worm:”—but it is only lately that it has been suspected that the said maggots and the said worms were aborigine part and parcel of this lord of the creation, as he was a compound of millions of their fraternity; and that as when a man has been devoured by maggots, it is only that his individuality is multiplied, so every time he takes a meal, it is only that the individuality of myriads of other organized beings is destroyed. “*Il n’y a point,*” says Cabanis, “*la mort pour la nature.*”

(d) G. R. Treviranus, &c.

(e) It would be a curious speculation to inquire, upon the principles of the advocates of this doctrine, in what way the determinate complement of the organic molecules in our planet has been, at any given time,

portion, at least, of extractive, sodo-albumen, &c., is certainly resolved into merely mineral substances in every instance of the decomposition of organic matters—else whence the carbonic acid, carburetted hydrogen, and ammonia which they evolve? and, as these substances must—unless the organic kingdoms of nature are, instead of increasing, gradually failing from off the face of the earth—be continually renewed, in the same proportion, by combinations of mineral substances, there seems to be no good reason why the whole of such substances should not be so resolved and so renewed. It would be premature in this place to expatiate on the obscure subject of generation, involving as it does the important question of the nature of life, which is so soon to occupy our attention; but it may be allowable to state here, that nothing hitherto adduced, in support of the hypothesis now under consideration, seems to be at all less easily explicable on the old doctrine of universally diffused germs, than on the new one of perpetually transmigrating organic molecules. With respect to the constant agitation of globules said to be observed in the infusions of organic matters during their spontaneous decomposition, a similar phenomenon has been noticed during the mechanical separation of particles of sulphur, flint, glass, manganese, and other mineral substances, in which the existence of organic molecules was out of the question (*a*); and with respect to the development, in the former, of mould and animalcules, when they have been exposed to heat, immersed in distilled water, and kept in vacuo, it is easy to conceive that minute germs may have been as competent to resist heat without destruction as organic molecules, and that such minute germs may as well have been contained from the first in and about the matters undergoing decomposition, as that they could find access to them only with the water or the atmosphere: nor will the countless myriads of new beings frequently so developed appear to be any objection to this explanation, when we reflect on the incalculable rapidity with which, once evolved, they perpetuate their species (*b*). Upon the whole, the difficulty of accounting, upon commonly received principles, for the phenomena in question, does not appear to be so great, as to warrant our adopting so overwhelming an hypothesis, in order to explain it.

All that has preceded appertains only to the differences in their structure between inorganic matters and organized beings, involving the consideration of their form, aggregation, substance, and composition: the next subject to be treated of is the differences in their actions. The following, then, are the chief characteristic actions respectively.

Of Inorganic Matters.

Those only by which their particles are held together, and by which they retain the same composition, substance, aggregation, and form, unalterably for ever, unless these are changed by some external agent.

Of Organized Beings.

1. Those by which they continually secrete and give off from their fluids, into the medium by which they are surrounded, certain gaseous substances, while they absorb from it others, for the purpose of effecting some necessary changes in the composition of these fluids. (*Respiration*).
2. Those by which they continually propel these fluids through the solid parts of their structure, for the purposes, on the one hand, of forming and depositing new solids and fluids, and, on the other, of breaking down and carrying away old ones, such of the latter as are useless being thrown entirely out of the system. (*Circulation, Nutrition, Secretion, Absorption, &c.*)
3. Those by which they at intervals receive from without certain solid and liquid substances, which they assimilate to the nature of the fluids so employed, for the purpose of renewing them in proportion as they become wasted. (*Digestion*).
4. Those by which they at intervals form and throw off certain organized parts, for the purpose of continuing their species. (*Generation*).

disposed of—that is to say, what proportion has been appropriated, first, respectively to the vegetable and animal kingdoms, and afterwards to each of the 56,000 species of plants, and 51,700 species of animals. It would appear that some of them must be very considerably minus what they were when the whole human race consisted of only a single pair, now that it numbers, at the lowest estimate, five hundred millions of individuals!

(*a*) Fray, *Sur l'Origine des Corps Org. et Inorg.* 1817. R. Brown. Brewster, Edinb. Journ. of Science, 1829.

(*b*) It has been computed by Linnæus that three flesh-flies and their immediate progeny will devour the carcass of a horse in less time than a lion could have done it, the female not unfrequently giving birth to 20,000 larvæ at a time, and a few days being sufficient for the production of a third generation.

Of Inorganic Matters.

[The duration of these matters, therefore, may be said to depend on their being allowed to remain unchanged—in other words, on their apparent repose (a).]

Of Organized Beings.

[All these actions are, under ordinary circumstances (b), essential, first to the continued existence of organized beings, as individuals, and secondly to their perpetuation, as species; consequently the duration of these beings may be said in general to depend on their being continually decomposed and recombined—in other words, on the obvious actions which are constantly going on within them (c).]

In addition to these actions of organized beings in general, are some others, commonly presumed to be proper to animals, and certainly requiring other conditions besides those which alone were necessary to the foregoing; such as—

5. Those by which they become conscious of impressions made upon them (*Sensation*).

6. Those by which, in virtue of this consciousness, they reason and will (*Thought*).

7. Those by which, in virtue of this will, they effect various movements (d) (*Voluntary motion*).

(a) The repose is here merely *apparent*, and the term is used, therefore, as opposed only to *obvious* action, since it is by a constant, insensible action—namely, by attraction and repulsion in one or other of their modifications—that repose itself is maintained. Even the *vis inertiae*, in every thing but the ultimate atom of matter, depends upon their exercise.

(b) The expression, “under ordinary circumstances,” is added for the purpose of meeting those extraordinary cases—some of which have been already alluded to—in which organism survives, for a longer or shorter period, the display of any obvious action whatever.

(c) Organized beings are accordingly compared by Cuvier—and well compared, notwithstanding the protest of Dr. Barclay—“à des espèces de foyers, dans lesquels les substances mortes sont portées successivement pour s’y combiner entre elles de diverses manières, et pour s’en échapper un jour, afin de reutrer sous les lois de la matière morte;” *Leçons d’Anat. Comp.*, 1799, tom. i, p. 5: and again, “la vie” says he, “est un mouvement de tourbillon, plus ou moins rapide, plus ou moins compliqué.” p. 6.

(d) It is usual to enumerate, among the characteristic actions of organized beings, those by which they evolve heat; and if this be done, we should specify also others by which many such beings evolve likewise light and electricity. But none of these phenomena are, in fact, proper vital actions, but the necessary physical results of some of those actions which have been above mentioned; and indeed the evolution of cold—if the expression may be allowed—is often not less remarkable as the result of such actions than that of heat, the balance on either side depending, in any given instance, on the comparative energy of those vital actions from which heat and cold respectively result. If it be admitted that the carbonic acid, which appears in respira-

tion, is not produced by the immediate combination of the carbon of the venous blood, in the lungs, and the oxygen of the air, as we are taught by the chemists, but secreted from the venous blood in its passage through the lungs, and that the oxygen which disappears is absorbed into the nascent arterial blood in the same passage—as has been elsewhere assumed, and as may be proved to be the case by all but conclusive evidence—if it be admitted—as it universally is—that, while there is very little difference in the density of venous and arterial blood, the density of carbonic acid considerably exceeds that of oxygen; and lastly, if it be admitted that there is little or no difference in the bulk of the secreted and absorbed gases—as has been abundantly established—the extrication of animal heat involves no new vital action, but is a necessary physical result of others; and the theory of this process—so long regarded as one of the most inexplicable problems—becomes one of the most simple and satisfactory in all physiology. The conversion of a liquid into a gas *must*, by rarefaction, produce cold, whilst the opposite conversion of a gas into a liquid, *must* by condensation, produce heat; and, the density of the two liquids being nearly the same, had the density of the two gases been so too—keeping in mind that their bulk is equal—the one process would have neutralized the other, and neither sensible cold nor sensible heat would have resulted. But the density of the two gases is not equal: the transition, therefore, of the liquid into the denser gas, produces less cold than that of the rarer gas into the liquid produces heat, and what is called organic heat is thus merely the result of the absorption of oxygen into arterial blood, *minus* that of the secretion for venous blood of carbonic acid; and when we reflect that in the human being the temperature of not less perhaps than ten pounds of arterial blood is sensibly raised by this means about 2 deg. every minute, as first insisted on by Dr. Holland,

These, then, are the chief distinguishing features in the actions of organized beings, and it is in the investigation of these that the science of **PHYSIOLOGY** properly consists. The several series of actions above enumerated, are their functions, the term function differing from the term action, as applied to such beings, only as being more comprehensive, and as having a reference always to some general end, the function of respiration, for example, including the actions of many different organs, all which, however, co-operate in effecting some necessary changes in the composition of the fluids (*a*). In this view of the matter, then, a function may be defined to be the action, not of an organ, but of an *apparatus* destined to some specific purpose in the general economy of an organized being; and it is only in this view of the matter that the functions of such beings are susceptible of enumeration or classification (*b*). Of the several series of actions, however, or functions, specified above, the four first are those by which, principally, organized beings are distinguished from inorganic matter, while the three last, on the other hand, serve chiefly to distinguish some kinds of organized beings from others.

of Sheffield, (Experimental Inquiry, &c., 1829), and that he has—not continually to extricate, *de novo*, as is idly imagined, a sum of caloric sufficient to constitute the whole difference between the temperature of his body and that of the atmosphere—but merely to keep up what is in any given time passing from him, we shall not require any aid from the latent heat doctrine—according to which, to say nothing of its numerous other stumbling-blocks, the venous blood ought to be hotter than the arterial—nor from any other, easily and satisfactorily to explain the whole process. Perhaps, indeed, the theory above proposed may be, as Magendie says, “trouvée trop simple;” but in the mean time, were the present the place for entering in detail into the subject, it would be easy to shew that, simple as it is, while it is supported by every fact which was at one time supposed so strongly to corroborate that of Black and Crawford, it is amenable to none of the objections which must be fatal to the latter, and at the same time explains many circumstances which neither this nor any other theory has approached. Calorification, then, is no more a vital action, *per se*, than frigorification, which has long by general consent been allowed to be the natural and necessary result of transpiration, the inconsistency, in the mean time, of attributing heat to one gaseous exhalation, and cold to another, having been overlooked. The secretion of carbonic acid is and must be directly a source of cold, but, the absorption of oxygen always corresponding with it, it becomes thus indirectly a source of heat; whereas, the secretion of halitus—so much rarer as it is, to begin with, than carbonic acid—is a source of unqualified cold, there being in this instance no counteracting power in operation.

(*a*) It is very important to keep constantly in mind the physiological distinctions between a property, faculty, quality, or capability, a power, stimulus or agent, and action or function; the first, like irritability, sensibility, and so forth, signifying only a susceptibility of excitement, the se-

cond, like caloric, light, sympathy, &c., only a means by which this susceptibility may be called into action, while the last, like irritation and sensation, signifies the phenomena resulting from the two in co-operation. It would have appeared almost superfluous to notice these distinctions, had they not been so frequently lost sight of, not only by the *οἱ πολλοί*, but even by authors of merited celebrity, Adelon, for instance, speaking continually of the *function* of sensibility, Barclay of the *property* of sympathy, and Bostock of the *power* of sensation.

(*b*) The enumeration of the functions has been from the most ancient periods almost the same as at present, the co-operation of the actions of several organs, if not the specific end in view, having from the first furnished certain broad principles upon which each might be distinguished from the rest; but the classification of them has been very various. By Aristotle, the first to attempt any regular arrangement of the functions of animals, they were classed under the three heads of Vital, Natural, and Animal; the two former including those which were common to plants and animals—the first, however, not allowing of interruption for an instant without danger of death, while the second allowed of a considerable interruption with impunity—and the latter including those which were regarded as proper to animals; and this classification, adopted as it was by Galen, became that of most physiologists almost down to our own times, nor have indeed very many years elapsed since the addition which the latter made to this system of classification, that over each of the heads of functions which it includes certain specific *Πνεύματα* or spirits, called respectively Vital, Natural, and Animal, presided, was abolished. By Paracelsus, one of the first original thinkers in after times, the vital and natural functions of Galen were spoken of as constituting one life—that which acted within an animal, and the animal functions as constituting another—that which acted upon surrounding bodies; and this was the basis of the arrangement of the functions proposed by Harvey under the

CLINICAL LECTURES

AT

JERVIS-STREET HOSPITAL, DUBLIN,

Delivered Session 1834.

BY DR. CORRIGAN.

LECTURE I.

Philosophy and Practice of Medicine—Diarrhœa.

GENTLEMEN—There are not, perhaps, two things often more opposite in appearance than the philosophy and the practice of our profession; not that they are essentially in contradiction to one another, but they are rendered so by injudicious attempts at simplifying.—Naturally they illustrate one another; and he will ever be the best physician who, from reflection and observation, combines them, the philosophy or principles of the science being first in his mind, and the practice or

application of remedies second, “but second without being inferior.” Artificially they are too often separated, and he is the worst physician who attaches himself exclusively to the one, or devotes his whole observation to the other; in the one case he becomes a visionary theorist, in the other, an ignorant and guess-working quack.

These observations have naturally arisen from, and an apt illustration of their truth is afforded by the disease which is the subject of our present lecture—diarrhœa; for, while the philosophy of medicine would prove to us that there is no such disease,—so say our Gallic “*sçavans*,” “*La diarrhée n'est qu'un symptôme et jamais une maladie*”—stubborn practice tells us there is. Philosophy may assure us that a patient who has died of diarrhœa ought not to have died, because diarrhœa was no disease, but only a symptom; but observation shews us that patient was sinking exactly in propor-

names of Vegetative and Sensitive—the former of which were supposed to be actuated by the $\psi\upsilon\chi\eta\ \theta\epsilon\sigma\tau\iota\kappa\eta$, and the latter by $\psi\omega\chi\eta\ \alpha\iota\sigma\theta\eta\tau\iota\kappa\eta$ of the ancients, or, as Harvey himself called them, the *anima vegetativa* and the *anima sensitiva*. Almost precisely similar to this, except in words, is the popular twofold arrangement of the functions followed by Bichat, his organic functions almost entirely corresponding to the vegetative, and his animal to the sensitive of Harvey; but he differed essentially from the latter in denying that they were the results of the operation of any $\psi\upsilon\chi\eta$ or *anima*, contenting himself with representing one general department of the nervous system—the ganglionic—as subservient to the former of these heads of functions, and the other—

the cerebro-spinal—to the latter. In quite recent times, the functions have been commonly classified according rather to the general purposes to which they minister in the animal economy than to any other condition; and upon these principles—which have been followed above—three heads of functions have been generally admitted, the Nutritive, or those which are subservient to maintaining the well-being of the individual, the Sexual, Generative or Reproductive, or those which serve to perpetuate the species, and the Relative, or those by which an intercourse or relation is kept up with the external world. Admitting, then, on all hands the same number of functions, the following is their classification by the above-mentioned authors:—

	ARISTOTLE and GALEN.	HARVEY, BICHAT.	More recent Authors.
Respiration	Vital.	Vegetative or Or- ganic.	Nutritive.
Circulation			
Nutrition and Secre- tion	Natural.		
Absorption			
Digestion			
Generation	Animal.	Sensitive or Animal.	Sexual, Generative or Respirative.
Sensation			Relative.
Thought			
Voluntary Motion			

It seems superfluous to notice certain other classifications of the functions proposed by Vicq. d'Azyr, Dumas, Buisson, Richerand, Cuvier, and others, in the attempt to attain absolute precision on a subject on which, from its very nature, absolute precision is not attainable, and on which, therefore, any great solicitude about it is vain and frivolous. It is enough that any ar-

range inculcates useful associations, and is conducive to perspicuity, to make it a good one; and that is the best, however logically defective, which conduces most to these ends. “Divisions,” says Lord Bacon, “only give us the husks and outer parts of a science, while they allow the juice and kernel to escape in the splitting.”

tion to the continuance of that diarrhoea, dying of it when not checked, or suddenly restored to health on the stoppage of the flux; and practice fortunately at the same time furnishes us with the means of cure.

There are several species of diarrhoea; but we must of course (not to ramble from the legitimate range of a clinical lecture) confine ourselves to the form immediately before us. I shall first notice the two cases the subject of the present lecture.

1st Case.—J. Walsh, *ætat* 36, a servant, admitted labouring under diarrhoea to the number of twelve or thirteen stools a-day; the stools are bilious and thin, but otherwise healthy-looking. There is general soreness, although trifling, over the abdomen; his appetite is very bad; there is nausea every morning, and sometimes vomiting. He has also troublesome fits of coughing, with muco-purulent expectoration; skin is hot and dry, and covered extensively with prurigo, which is extremely annoying; tongue dry and parched; pulse 86, weak; no pain of chest; no dullness on percussion, or any stethoscopic indication of phthisis. About three months ago he caught catarrh, which was succeeded by swelling of the abdomen and flatulence of the stomach, and for a fortnight the purging has been present to the extent described.

2nd Case.—Val. Gorman, *ætat* 48, a carpenter, of temperate habits, admitted the same day as Walsh. He complained of a general soreness over the abdomen, with frequent calls to stool (about fifteen times in twenty-four hours), followed by dejections of yellow, bilious, feculent, matter, without any pain. There is pain on pressure in the right hypochondrium, the epigastric region, and along the ascending and transverse colon; pains shooting up the thorax and out at the back, and wandering pains of the extremities. There is no headache, no tenesmus; pulse 96; skin natural; much thirst; tongue dry; appetite impaired; great emaciation. He states that the diarrhoea commenced about six weeks back, and that he first felt soreness of the abdomen a fortnight since.

Now, having read the cases, the first question that naturally suggests itself to an inquiring mind, and which I would always recommend you to ask yourselves mentally at the bed-side in every case, is this: If the patient now before us were to die at the present moment, what are the diseased changes which would present themselves on a *post mortem* examination, or in more technical and shorter language, what is the pathology of the disease? If you make it a rule never to prescribe for a patient without mentally asking that question, and diligently seeking to arrive at the answer, believe me that simple rule will bring you to a clearness of diagnosis, and will give

you a steadiness in practice, which you never can otherwise acquire. In the present instance, let us endeavour to answer such a question in respect to the two cases now before us.

A patient, James Brady, died in this hospital of the same disease, diarrhoea, four months ago. His case in the commencement differed in no respect from the two cases above given, but that when admitted, from the duration of the attack, and the extreme emaciation and debility under which he laboured, the time had past by for expecting any benefit from medicine. He laboured under the same kind of diarrhoea; the stools yellow, bilious, feculent, and fluid; no tenesmus, no pain—pulse regular. The emaciation and debility were extreme at the time of his death, which occurred seven months after the commencement of his attack. I will now read from the note-book the appearances on dissection. The stomach, small intestines, and colon, in a state of cord-like contraction. The stomach internally healthy: the small intestines looking very thin: portions of the mucous membrane congested and softened: the submucous tissue healthy: no ulceration in the ileum, which was congested at its lower extremity. The mucous membrane of the colon and rectum, congested through a considerable portion of its extent, and studded, particularly in the sigmoid flexure of the colon, with very minute circular pin-sized follicular ulcers, with pale yellow bases. The contents of the intestines very small in quantity, fluid, and similar to the evacuations during life. Gall bladder full of healthy bile, &c. Thus we have information as to the nature of the cases now before us, from the very best source, namely, the examination of a similar case which terminated fatally; and in every instance, where possible, I shall follow this plan of giving you information as to the nature of cases under treatment, by presenting to you the preparations taken from similar cases ending in death, selected either from our own records or obtained from trustworthy sources. The preparation now before you is the sigmoid flexure of the colon, contracted and studded with the very minute ulcers I have just described: and I may just digress for a moment to draw your attention to this, that the intestines, in Brady's case, were found *firmly contracted*.

I draw your attention to this, because such a contracted state of the intestinal canal in *post mortem* examinations of peritonitis or ileus, is called spasm, and is supposed to be the cause of the obstinate constipation which accompanies these diseases: and from this too generally received explanation, is deduced a line of treatment not only unsuccessful, but, I believe, often fatal. The supposition of the contraction of the canal being spasm, or being the cause of the constipation, has been combated, and

successfully, I think, by Dr. Abercrombie : and he is strongly borne out by the dissection of Brady's case, for, not only without constipation, but with frequent stools up to the last moment of life, there was found, on examination after death, firm and cord-like contraction of the intestines. To return, however, to our immediate subject, we learn from the examination of the intestinal canal in Brady's case, as similar as it is possible for one case to be to another, to the cases which are the subject of the present observations, that there may be diarrhoea to such an extent as to destroy life by emaciation and debility, and yet the organic alterations of structure may be very trifling; for the visible alterations of tissue, the congestions, softening, and trifling ulcerations of the mucous tissue, are very much below what we often find after death, in cases where there had not been similar diarrhoea; and indeed in Brady's case it is far more probable that they were the effect of the long-continued diarrhoea, than that the congestion and very minute ulcerations should have preceded the diarrhoea as a cause, and yet at the end of seven months have advanced no further than the degree at which we found them. We must then consider the diarrhoea in the case of Brady and in the two cases now under consideration, as very nearly a purely functional affection arising from a too great irritability either of the mucous membrane or of the muscular tissue, or of both, that morbid irritability not permitting the intestinal contents to remain in the canal, but in fact placing the patient for months in the state of a person under the continued influence of saline or hydragogue purgatives. This continued irritation is very likely to cause structural disease, such as found in Brady's case, and it also sometimes entails disease of other organs.

There was found in Brady's case a change of texture in the lungs, which seems to be an alteration of those organs, attendant on all diseases where there had been long continued debility, exhaustion, and emaciation. It is found in patients who have died of diabetes, of dropsy, of diarrhoea, of chronic disease of the liver. A portion of one or both lungs, generally the upper lobe, is found of a much darker colour than natural, not the colour of congestion, but as if the natural dark colouring matter were in great abundance; the moderate sized bronchial tubes are permeable, the smaller all closed; the lung not crepitating, and most generally with tubercular deposition in varying quantity. This change appears to be the consequence of there not being sufficient exercise for the whole organ, from the great diminution of the mass of blood during a long wasting illness, and the portions not required as it were any longer to carry on their functions, then undergoing this peculiar degeneration. In diarrhoea, the mucous membrane of the lungs very frequently

sympathizes with that of the intestines, and then, in conjunction with the affection of the intestinal canal there is catarrh, with copious muco-purulent expectoration, as in Walsh's case. This abundant purulent expectoration, the fits of coughing which belong to catarrh, the diarrhoea, and the wasting, which is often extreme, makes such a case of diarrhoea bear a very strong similitude to phthisis, causing a great anxiety in the minds of patients and friends. We are, however, generally able to diagnosticate with certainty. The history of the case tells us that the diarrhoea was first in order; in phthisis it never is. The most careful examination by percussion and auscultation discovers nothing morbid in the lungs, and there are, in addition, two other sources of diagnosis on which I would place even more reliance; these are the pulse and skin. The hectic of phthisis is wanting in diarrhoea, and the pulse, even in the worst and longest continued diarrhoea, unless from some temporary exciting cause, is very little above the natural standard. In most cases in private practice, where the patient can avoid cold, and any exciting cause, the pulse remains perfectly regular. Another close sympathy of the portion of the intestinal canal engaged in diarrhoea is with the œsophagus and stomach, so that no sooner is food received into the stomach than the sympathetic irritation (though the intestines had been up to that moment quiet) is felt in the large intestines, and the patient is suddenly obliged to leave a meal. This diarrhoea taking place during meals is particularly observed in children, who have not yet acquired or do not exercise the power of controlling the action of the rectum and sphincters; the sudden action of this sympathetic irritation is properly expressed by the phrase that the drink which the child takes "runs through." The sympathy which is thus observed to exist between the opposite extremities of the intestinal canal is in accordance with what we observe elsewhere of sympathy, for example, between the neck of the bladder and the extremity of the urethra in the glans penis. Sometimes the sympathy is carried farther, and I have seen patients who, while suffering under diarrhoea, accompanied with soreness (a very frequent symptom) along the course of the colon, feel a similar soreness in some part of the œsophagus, at one time higher at another lower, aggravated when the diarrhoea was severe, diminishing with the lessening of the diarrhoea, and finally disappearing altogether with its cessation. This sympathy of the œsophagus deserves more attention than is often paid to it. I have seen a case of spasm of œsophagus which lasted for years. It came on at meals, and often arrested the morsel so suddenly as to produce dread of instant suffocation. From its long continuance, it was at length supposed to arise from organic structure, and applications of various kinds were made,

and made in vain, to the neck. The patient, a lady, suffered all this time under most obstinate constipation; the rectum was kept in a state of constant spasm by the presence of a cluster of mulberry tumours within it, and which protruded after every stool, causing great suffering. These I at length prevailed upon her to allow me to remove by brushing them well with concentrated nitric acid. They sloughed away, and the constipation and the spasm of the œsophagus disappeared together. In the instance of soreness of the œsophagus there was also a tender and excoriated state of the vagina, and for some time after the diarrhœa had been cured, with each return of the menses there was felt, although in a diminished degree, the original sensation in the œsophagus. I have now mentioned most of the remarkable symptoms that occur to me as accompanying that form of diarrhœa now before us. You will observe that it has no relation to dysentery; there is no mucus, no sanguinolent discharge; no scybala, no tenesmus; it is not the form of diarrhœa mentioned by Dr. Elliston as cured by sulphate of copper, in which the stools are pasty and white, generally found in connexion with chronic disease of liver. In the form of diarrhœa now before us, the functions of the liver are healthily performed, the liver is sound, and the discharges are quite healthy in colour and appearance, only more fluid than they ought to be, resembling those procured from the intestines of a healthy person by saline purgatives, or more nearly, perhaps, the fluid fecal matter which we so frequently find in the extremity of the ileum in our *post mortem* examinations of healthy intestines, and it is highly probable that it is this very fluid fecal matter which constitutes the loose and frequent stools of the form of diarrhœa now before us, passed too rapidly on, in consequence of the morbidly increased excitability of the colon. Mercury, which is a remedy so often employed whenever the practitioner is in doubt from difficulty in the case, or from ignorance on his own part, is positively injurious in the disease now before us. I have seen it do mischief; I never saw it effect good. The medicine which I have used with such benefit in Walsh's and Gorman's case, and on which I have indeed very great reliance, is logwood in the form of decoction, a wine-glassful three times a day. The case which first strongly impressed upon me its good effects was one in private practice, where the disease had lasted with very little alleviation for nearly two years. The patient, a lady, had in succession run through chalk mixtures without end, opiates, all the astringents in the pharmacopœia, both by mouth and by enema, and had changed scene and air, and all in vain.

She had almost given up all hopes of relief, and the emaciation was proceeding "*pari passu*" with the diarrhœa when I put her on the decoction of logwood. The good

effects were apparent within less than two days from her commencing this remedy, and in less than a fortnight she was completely recovered. In that case there was great emaciation, cough, heat, and soreness in the œsophagus, and aphthous ulceration of the mouth. A case very similar in its symptoms is related by Dr. Abercrombie in his work on diseases of the stomach and intestinal canal, and it was from the perusal of his case, and of the good effects of logwood in it, that I was led to employ it in the case I have briefly narrated. I am sure that logwood has some specific effect on the intestines, or on the vessels of the mucous membranes. It is not at all so strong an astringent as many of those remedies which failed in cases where it has succeeded. Its decoction does not produce a precipitate with gelatine, and probably its specific effect is due to some other principle besides the small quantity of tannin it contains—perhaps to the hematine. I am at present trying the effects of hematine; as yet I can say nothing as to its value. Walsh was perfectly cured of the diarrhœa in 14 days from the date of the commencement of his using the decoction. Gorman was discharged cured in 20 days, and would have been sent out sooner, but that on the ninth day after his admission we were obliged to discontinue the logwood, from his showing some symptoms of general fever, which, however, soon subsided under the exhibition of the common acetate of ammonia mixture. In both Walsh and Gorman's case, about ten drops of aqua kali caustici were given occasionally, with each dose of the decoct. hæmatoxyl, on account of some acidity of the stomach. Walsh laboured under very extensive and aggravated prurigo, which was rapidly removed by a lotion of hydrarg. oxym. 3ij, aqua puræ 3xvi, acid. hydrocyan. 3ij.

It may be well perhaps here to observe, that there is frequently a symptom accompanying long continued diarrhœa, which, if inclined, from the perusal of French writers, to pay too much attention to, enteric irritation might unnecessarily prevent you from exhibiting logwood, that is, a soreness very frequently felt extending from the right iliac region across the epigastrium, and then downwards on the left side. This soreness complained of by the patient might perhaps induce you to unnecessarily apply leeches, &c. to subdue it. It is, however, scarcely increased on pressure, is of that species which the patient describes as internal soreness, has its seat I believe in the colon, and is owing merely to the very frequent action of this intestine, similar in kind to the soreness left after the operation of a smart purgative. It disappears with the cessation of the diarrhœa.

In cases of diarrhœa, attention to diet is of the greatest importance. If the patient mingle together in his intestines a variety of articles of food, our medical treatment

will be of very little use. Whatever diet is found to answer best should be continued, with as little mixture as possible. If farinaceous diet, that should be adhered to as strictly as possible; if animal food be allowed, the patient should limit himself to one kind. The intestine becomes thus accustomed to the nutriment received, and is much less irritated than when successive impressions are made upon it by varying articles of diet. This rule of confining the patient as far as practicable to one species of nutriment, is applicable not only to solid food, but is even, in the administration of drinks, a means of no inconsiderable power in controlling the troublesome diarrhoea of some fevers, and the frequent evacuations which form sometimes so troublesome an accompaniment of enteric irritation in children. There are other means besides the exhibition of the decoction of logwood and the attention to diet, which are useful in the treatment of diarrhoea. Flannel should invariably be worn next the skin, and very large opiate plaister over the abdomen, whether it act by warmth or by absorption, is frequently of use. A small quantity of Dover's powder, 3 or 4 gr. at bed-time, although of itself totally inefficacious, becomes an useful adjuvant, and particularly where it produces, as it frequently does, an eruption of urticaria. The success which has attended the exhibition of logwood in the cases I have described induced me to try it in other diseases. In a case of hæmorrhagia of the passive kind, which occurred in a patient ætat. 22, and had lasted for two years with little intermission, partially checked by rest and sea-bathing, with iron, but never cured, and which had resisted lead and all the usual remedies, the extract of logwood given three times a day with mist. ferri aromatica has been perfectly successful. I intended to proceed with the consideration to day of the case of "Button scurvy," a very singular disease; but as time will not permit, we must defer it to our next lecture.

A NEW PRACTICAL FORMULARY OF HOSPITALS, OR A

Collection of Formulæ of the Civil and Military Hospitals of France, Germany, Italy, Great Britain and Ireland, &c., containing the Indication of the Doses in which simple Substances, magistral and officinal Preparations of the Codex are administered, the use of New Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M. D., and P. VAVASSEUR, M. D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M. D. &c. &c.

(Continued from p. 124.)

Boluses of Squills. H. de la Mat.

Rx. Pulveris scillæ, 3j;
Potassæ sulphatis, ʒj;
Oxymellis scillæ, q. s.

Divide in bolos xij quorum sumat duos quotidie.

Employed in certain dropsies.

Each bolus contains gr. iij of squills.

Diuretic Pills. H. of Italy.

Rx. Pulveris scillæ, gr. xx;

———— digitalis, gr. xvij;

Succi juniperi, q. s.

Fiat massa in pilulas x dividend. é quibus sumat unam omni horâ.

Each pill contains gr. ij of squills.

Hydragogue Pills. H. de Mont.

Rx. Scillæ, 3vss.

Extracti colocynthidis 3v.

Misce et divide in pilulas cc de quibus capiat unam mane nocteque.

Each pill contains about gr. ij of squills; the dose may be progressively increased. After taking them, the patient should drink a small quantity of an infusion of holly-oak.

These pills are purgative and diuretic.

Compound Pills of Squills.

Rx. Pulveris scillæ,

———— digitalis,

Extracti acetosellæ, ā ā 3j.

Fiat massa et divide in pilulas lxxij, e quibus iij ad ix capiendæ quotidie.

In dropsy.

Each pill contains gr. i of squills.

Compound Pills of Squills. Lond. H.

Rx. Scillæ radice recentis exsiccatae, 3j;

Zingiberis radice contritæ,

Saponis duræ, ā ā 3ij;

Ammoniacæ contriti, 3ij.

Syrupi simplicis, q. s. fiat massa cujus gr. iv ad xii sumendæ quotidie.

As an expectorant, in chronic affections of the thoracic organs.

Twelve grains of this mass contain about two grains of squills.

Expectorant Pills. H. of Eng.

Rx. Scillæ, 3ss;

Myrrhæ, 3jss;

Extracti hyoscyami, 3ij.

Aquæ q. s. divide in pilulas xxxvj, quarum sumat duas in die.

In chronic pulmonary catarrh, &c.

Each pill contains gr. i of squills.

Decoction of Squills. H. Italy.

Rx. Scillæ, 3j;

Juniperi, 3iv;

Polygalæ senegæ, 3iij;

Aquæ, Oj.

Coque ad dimidiam, cola, et adde,

Ætheris nitrosi, 3ss.

Misce; decocti hujus sumat cæger cochleare dimidium secundâ quaquâ horâ.

This preparation is a powerful diuretic, and is very useful in dropsy.

Diuretic Potion. H. de la Ch.

Rx. Mellis scillæ, 3iv;

Ætheris nitrosi, 3i;

Liquoris opii, 3ss;

Aquæ destillatæ valerianæ,

———— menthæ piperitæ, ā ā 3iv;

Syrupi simplicis, 3j.

Fiat potio, cujus sumat cochleare unum, secunda, vel, tertia, quaquâ horâ.

In anasarca arising from disease of the heart, &c.

Potion of Squills. H. Militaire.

R_x. Oxymellis scillæ, ʒ ss;
Infusi hyssopi, ʒ iv;
Acidi nitrici alcoholizati, 3 ss.

Misce; cochleare sumatur pro dosi.
As a diuretic.

Diuretic Potion. (H. N. D.)

R_x. Decocti, ʒ iij;
Aquæ florum aurantii, ʒ ss;
Oxymellis scillæ, ʒ ij;
Syrupi simplicis, ʒ j;
Liquoris opii,
Tincturæ castorei,
———— moschi, ā ā gutt vj;
Alcoholis nitrici,
Ætheris, ā ā gutt x.

Employed in treating certain dropsies.

Pectoral Mixture of Boerhaave.

R_x. Aceti, scillæ, ʒ vj;
Oxymellis scillæ, ʒ iij;
Sodæ sulphatis, ʒ j;
Decocti hordei, ʒ viij.

Fiat mistura, cujus, ʒ j sumatur singula semi hora.

Pectoral Looch. H. of Germ.

R_x. Oxymellis scillæ,
Syrupi althææ,
Mucilaginis gummi acaciæ, ā ā
p. e.

Misce, cochleare unum sumendum secunda quaquâ horâ.

In chronic pulmonary catarrhs.

Diuretic Mixture. H. of Amer.

R_x. Tincturæ scillæ, ʒ ij;
Ætheris nitrici, ʒ j.

Fiat mistura cujus sumat cochleare minimum quinquies vel sexies in die e cyatho infusi gentianæ.

EXTERNALLY.

Gargle of Squills. (Swedish).

R_x. Oxymellis scillæ, ʒ j;
Aquæ cinnamomi, ʒ x.

Fiat gargarisma.

As a stimulant in chronic angina.

Diuretic Liniment. H. of Italy.

R_x. Pulveris scillæ, ʒ j;
Succi lini vituli, ʒ ij.

Fiat linimentum.

Frictions should be made morning and evening, in cases where the patient is not able to take the preparations of squills internally.

Diuretic Ointment. H. of Italy.

R_x. Unguenti hydrargyri, ʒ j;
Pulveris scillæ, 3 ss.

Misce.

Used in frictions on the internal parts of the

thighs, and on the abdomen, in the same cases as the preceding preparation.

Medicinal, or Almond Soap.

A stimulant of the digestive organs, but more especially a diuretic. Like other alkaline preparations, it is used with advantage in gravel, and is useful in softening indurations, scrofulous tumours, &c. Externally, it is used in the treatment of indolent tumours, &c.

Subst. incomp. Acids, and all soluble salts, except those of soda, potassa, and ammonia, substances which contain tannin, &c.

INTERNALLY. Gr. x—3j, in pills.

Pilules de Savon. P. Gr. x—ʒij.

The *Pilules de Savon* of the H. de la Ch., differ from those of the codex, in not containing nitre; they are composed of grs. ij of the soap, and the powder of marshmallows. They are used as laxatives.

Compound Pills of Soap. H. de la Ch.

R_x. Saponis medicinalis, (vel amygdali), gr. vj;
Hydrargyri submuriatis;
Pulveris jalapæ, ā ā gr. iij.

Divide in pilulas tres, quarum capiat unam secundâ quaquâ horâ.

Alterant Pills. (Alibert).

R_x. Saponis medicinalis (vel amygdali), ʒ ij;
Extracti aloes,
Potassæ supertartratis, ā ā ʒ j;
Syrupi simplicis, q. s.

Divide in pilulas xcvj, quarum ij ad iv sumenda quotidie.

Pilules Fondantes. Hot. D.

R_x. Saponis medicinalis (vel amygdalis), ʒ iij;
Gummi ammoniaci,
Rhei, ā ā ʒ j;
Extracti aloes, gr. x;
Assafœtidæ,
Crocii, ā ā ʒ ss.

Divide in pilulas singulas, gr. iij, quarum sumat iv ad vj in die.

Bolus Savonneux. H. of Germ.

R_x. Saponis medicinalis (vel amygdali), ʒij;
Olei carui gutt., iij,
Syrupi tolutani, q. s.

Fiat boli iv, quarum sumat iv vel vj in die.

As purgatives.

Sometimes extracti aloes, grs. iv is added to render them more active.

Looch Savonneux. H. of Germ.

R_x. Saponis medicinalis (vel amygdalis), ʒ j;
Olei amygdalæ dulcis, ʒ j;
Syrupi mannæ, ʒ jss.

Cochleare magnum sumatur pro dosi.
As a laxative.

EXTERNALLY. In lotions, fomentations, and frictions, q. s. dissolved in alcohol or water.

Emplâtre de Savon. P. Résolutive.

Honey Soap. H. of Italy.

Rx. Saponis medicinalis (seu amygdali),
Mellis, āā ʒ iv;
Potassæ subcarbonatis, ʒ ss;
Aquæ fumaris, ʒ ss.

Misce.

Employed in frictions to cause resolution of indolent tumours.

Enema of Soap. H. of Italy.

Rx. Saponis medicinalis (seu amygdali), ʒ j;
Mellis, ʒ vj;
Decocti hordei, ʒ vj.

Fiat enema.

Laxative Suppositorium. H. of Italy.

Rx. Saponis medicinalis (seu amygdali), ʒ ij;
Sodæ muriatis, ʒ j;
Mellis, q. s.

Fiat suppositorium magnitudinis solitæ.

Cataplasm Maturatif. H. of Germ.

Rx. Saponis duri, ʒ j;
Micæ panis, ʒ viij;
Lactis, Oj.

Decoque.

Decoct for some time.

Used to hasten suppuration in phlegmon.

Fomentation of Soap. Hot. D.

Rx. Saponis medicinalis (seu amygdali), ʒ ss;
Spiritus rectificati, Oij. liqua.

Employed in spasms, contusions, &c.

Lotion of Soap and Alcohol.

Rx. Saponis medicinalis (seu amygdali), ʒ iv;
Alcoholis, Oj. liqua.

Employed with success in the treatment of scabies.

This lotion has the advantage of not soiling the linen, but it is rather expensive. In the Hot. St. Ant. this preparation is called *Liniment savonneux alcoolique*.

The *Lotion alcoolique savonneuse* of the H. des Inf. contains but half this quantity of soap, and is used in the same cases.

Acetate of Potassa.

In small doses, this substance is diuretic, and may be employed in the same cases as the above-mentioned medicines.

Subst. Incomp. The greater part of fruits, almost all acids, and many salts.

INTERNALLY. As a diuretic; the dose is ʒj — ʒj, in solution, several times a day.

As a cathartic, ʒvi — ʒj, and more.

Liquid Acetate of Potassa. H. of Germ.

Rx. Potassæ acetatis, unam partem,
Aquæ destillatæ, duas partes.

Liqua. Dosis ʒj vel iij.

Another. (Jackson.)

Rx. Decocti genistæ recent., ʒxij;
Potassæ acetatis, ʒij;
Sp. armor. comp., ʒj.

Sit mistura, de qua capiat ʒiiss, ter quaterve in die.

The acetate of potassa is also combined with compound spirit of juniper, digitalis, nitrous ether, colchicum, &c.

Simple Diuretic Ptisan. H. of Italy.

Rx. Potassæ acetatis, ʒij;
Decocti graminis canini, Oj.

Misce.

Cyathus sumatur pro dosi.

Diuretic and Sedative Potion. H. de Mont.

Rx. Potassæ acetatis;
Oxymellis scillæ, āā ʒj;
Liquoris opii (Sydenham), gutt., xv;
Aquæ tilis, ʒiv;
Syrupi, ʒj.

Fiat potio, cujus capiat cochleare pro dosi.

Diuretic Potion. Hot. D.

Rx. Vini albi, Oj;
Liquoris potassæ acetatis, ʒj.

Fiat potio, cujus sumat æger cyathum pro dosi.

Used in dropsy, anasarca, &c.

Potion, with the Acetate of Potassa. H. de la Mat.

Rx. Potassæ acetatis, ʒij;
Syrupi aceti, ʒj;
Aquæ cinnamomi, ʒj;
Infusi tilis, ʒiv.

Fiat potio, cujus sumat cochleare pro dosi.

As a diuretic, and in some organic affections of the abdominal viscera.

[*Diuretic Powder.* (Ryan).]

Rx. Pulv. jalapæ comp., ʒvj;
—— scillæ,
—— digitalis,
—— hydrarg. submur., āā gr. xij;
—— cinnamomi comp. ʒj;
antimonialis, gr. xij.

In chartulas xij, divide quarum sumat unam mane nocteque.

These powders are diuretic, diaphoretic, and cathartic; are extremely efficacious in dropsies which do not depend on organic disease of the heart, liver, or kidney. I have used them for ten years at the different public institutions of which I am, or have been physician, and in general with great advantage, as a vast number of students can testify. T.]

Antilacteal Bolus. H. de Lyons.

Rx. Potassæ acetatis, ʒj;
Conservæ calendulæ, q. s.

Fiat bolus.

To be taken during twenty mornings, to prevent hardening of the breast.

A cupful of a ptisan, made of herbs, should be taken immediately after it,

[*Diuretic Pills and Potion.* (Pearson).

R_x. Pulv. digitalis,
—— scillæ, āā gr. ix;
Extracti gentianæ, ℥j;
Olei juniperi, M. viij;
Syrupi simplicis, q. s.

Fiat massa in pilulas xij, dividenda quarum sumat unam bis vel ter in die cum haustu sequenti:—

R_x. Aquæ ferventis, ℥jss;
Potassæ supertart., ℥j—ij;
Sp. juniper. comp., ℥ij;
Tinct. cinnam. comp., ℥j.
T.]

Acetate of Soda.

This ingredient possesses the same qualities as potassa, but its action being less than that of potassa, it is consequently not so much used. The dose is ℥ij—℥iv, in a proper vehicle.

UREA.

According to the observations of M.M. Segalas, Fouquier et Barbier, this immediate principle appears to possess very remarkable diuretic properties. It is not much used,

INTERNALLY. Its dose is grs. xx—℥ij dissolved in sugar and water, in cases which require other diuretics.

ASPARAGUS (ROOT).

An active diuretic and aperient. Frequently used in dropsy, and in diseases of the urinary organs. The buds of the asparagus appear likewise to possess a sedative property. This substance is likewise used in hypertrophy of the heart, to calm the palpitations.

INTERNALLY. Decoction, ℥ss—i in Oij of water.

The dose of the *Apozeme des Cinq Racines*, P. is a small cupful at a time.

Sirap de Cinq Racines. P. ℥ij—℥i, to sweeten ptisans, and diuretic potions.

Diuretic Decoction.

R_x. Radicis asparagi,
—— cochleariæ, ā ā ℥i;
Baccarum juniperi, ℥ij;
Marrubii, pine, i;
Aquæ ferventis, Oj.

Decoque, per horam unam, et cola.

Cyathus sumatur misturæ hujus, omni mane.

To each glassful is added a spoonful of the following mixture:—

Syrupi scillæ,
Syrupi, āā ℥ij.

Another Diuretic Decoction.

R_x. Radicis asparagi, ℥j;
Aquæ, Oj.

Coque cole et adde,

Potassæ acetatis, gr. viij.

Decocti hujus, cochleare, sumatur pro dosi.

BUCHU.

A diuretic, and stimulant of the urinary organs. Employed with success in catarrhus vesicæ, retention of urine through weakness of the bladder, diseases of the prostate gland, the gravel, &c.

INTERNALLY. Powder. ℥j—℥ss daily in white wine.

Infusion. ℥ij—℥iv. to Oij of water, of which a small cupful should be taken, about every four hours.

Tincture of Buchu. Dublin.

R_x. Buchu, ℥ij;
Alcoholis, Oss.

Fiat tinctura, cujus ℥i—℥ij, sumat pro dosi.

Compound Infusion of Buchu. H. of Eng.

R_x. Infusi buchu, ℥ viij;
Tincturæ buchu,
——cubebæ, āā ℥j;

Fiat infusum, de quo sumat ℥j, ter in die.

[*Compound Mixture of Buchu.* (Ryan).

R_x. Infusi buchu, ℥ vj;
Tinct. ejusdem,
Tinct. cubebæ, āā ℥j;
Balsam. copaibæ, ℥i—iv;
Liquoris potassæ, ℥j;
Olei menthæ, virid. m v;
Tinct. opii, ℥j;
Mellis despum., ℥vj.

Sit mistura, cujus capiat cochleare amplum ter quaterve in die.

This will be found a valuable combination in gonorrhœa, leucorrhœa, and gleet.
T.]

(To be continued).

Review.

A Treatise on the Formation, Constituents, and Extraction of the Urinary Calculus. By John Green Crosse, Surgeon to the Norfolk and Norwich Hospital, &c. &c. London: John Churchill. pp. 231. 4to. and plates.

To surgeons and chemical philosophers the subjects of this treatise presents points on which much patient research and great ingenuity probably remain yet to be exercised. Of late years neither of these qualities have been wanting: the re-agents of the chemist have rapidly developed the constituents of the calculus which the operations of the surgeon extracted: and at this time we have arrived at considerable accuracy as to the former, while the modes of extraction are yearly becoming more perfect, by the combination of diminished pain during the operation, and of diminished danger consequent upon it.

Such, however, is not the success in the discovery of the causes on which the formation of the calculus depends, and Mr. Crosse announces an undeniable fact when he states at the commencement of the first chapter, that "few subjects in medical science are involved in greater obscurity than the formation of urinary calculi." This ignorance, however, more particularly refers to the immediate train of phenomena by which the constituents of the urine come to be so changed or exaggerated in quantity as to form calculi. There are certain causes acting generally on the process of digestion, which are too palpably concomitants of such formation to admit a doubt of their influence on it. Accordingly we find, in this treatise, *dyspepsia* prominently advanced as one of the causes of urinary calculi; and though *dyspepsia* is frequently found without calculus, it is equally certain that disordered urine ever accompanies disordered digestion: it requires only the addition of other exciting causes, "as want of exercise, variable climate, peculiar diathesis, or local disease in some part of the urinary organs," to originate calculous concretions. Besides *dyspepsia*, Mr. Crosse accuses over-exertion of the kidneys as a cause of calculus: this is more likely to take place in circumstances where the skin is exposed to influences which check its function of transpiration, while by the well-known sympathy between that surface and the kidneys, the function of the latter is inordinately put into play, and therefore made more liable to disease. In the previous paragraph the author mentions the excess of spirituous fluids and of alkalies as causes of the disease in question. Would it not be reasonable to suppose that these also act by inducing the inordinate action alluded to? In the county of Norfolk, where calculous disorders are so rife, there would appear to be an unlucky combination of causes, and Mr. Crosse is of opinion that "the great prevalence of a north-east wind, and the frequent, sudden, and very considerable changes of temperature acting upon persons already affected with the most prevailing disorders of the district, *dyspepsia*, *scrophula*, or *rheumatism*, cannot but be regarded as most powerful agents in giving rise to such frequent cases of gravel and stone."

The local causes of calculous disorders are

severally mentioned to be external violence, injuring the structure of the kidneys, stricture, hypertrophy of the prostate gland, hernial displacement of the bladder, sacculi of the inner membrane of the bladder, extraneous substances, and sedentary habits. With regard to the *modus operandi* of these causes, some act by disorganizing the tissue of the kidney, and others by retaining the secreted urine, and inducing catarrh. Of prostatic enlargement he observes, that "it disposes to calculous disorders, both in the kidney and bladder, particularly in the latter, by inducing chronic inflammation and a catarrhal state of the inner coat of the organ, by keeping a quantity of urine always stagnant in the bladder, and by penetrating outwards through the urethra of smaller concretions."

Chapter the second treats of the chemical composition of urinary calculi. As separate treatises on this subject are plentiful, we shall merely give the particular experience of the author in the relative proportion of the various kinds of stone; his opinion as to the part more especially the subject of analysis is also worthy to be quoted; both are comprised in the following paragraph and table:—

"The analysis of every part of a calculus is of use; but the nucleus is calculated to excite most interest, because its analysis bears so directly upon the prevention of the disease; nearly all calculi situated in the bladder are formed upon nuclei of smaller calculi, originating in this organ or descending from the kidney, and of a size that would allow of their passing away by the urethra; hence it follows, that calculi of small size, such as often pass away spontaneously, resemble the nuclei of larger calculi, and are more deserving of being examined chemically than the surfaces of calculi found in the bladder after death, or removed by cystotomy. Entertaining this opinion, I began several years ago to collect all urinary concretions passed per urethram; and the first hundred, obtained from the male, being analysed before receiving a place in my cabinet, gave this result:—

Lithic acid or lithate of ammonia	72
Lithic acid and oxalate of lime	9
Oxalate of lime	14
Carbonate of lime	1
Triple phosphate	2
Fusible	2

Total . 100 "

The mechanical composition and growth

of vesical urinary calculi occupy the third chapter. Lithic calculi are of slowest growth, increasing at the rate of between one and two drachms in a year, rarely exceeding the latter. Calculi of the phosphates are in all respects the worst forms of the disease; they frequently accumulate with great rapidity. The most slowly formed calculi are generally the most dense and heavy: those formed rapidly present the opposite qualities. Mr. Crosse insists on the importance of studying the nuclei of urinary concretions as a necessary aid in the diagnosis.

In chapter 4th, calculi in the kidneys and ureters, and their pathological effects, are treated of. Several autopsies are given in illustration: the following familiar picture of the process of infundibular expansion is sufficiently happy:—

“The expansion of the pelvic and infundibular cavities of the kidney into one large bag, in which all trace of the original form is nearly obliterated, may be comparatively explained by a glove of indian-rubber, in which the part covering the wrist would answer to the ureter, that upon the palm of the hand to the pelvis, the fingers to the infundibula, and the tips of the fingers to the situation of the calyces; by inflating and enlarging this glove powerfully enough, the fingers would become obliterated and the whole expanded into one large cavity; precisely what happens to the dilatable and elastic membrane of the cavities of the kidney: and the comparison is not weakened by the infundibula being about twice as numerous as the fingers of the elastic glove.”

The facts connected with the presence of renal and uretral calculi are also summed up with much felicity.

“The evils produced by renal calculi are not to be measured by their size; a small passable calculus, in its course along the ureter, causes most severe and acute symptoms, which every practitioner is familiar with; a calculus firmly impacted in and filling the ureter, sometimes gives little pain, although leading to complete destruction of the renal organ: whilst a large calculus occupying the pelvis, and allowing the urine, as it is secreted, to pass on towards the bladder, with much pain brings no immediate danger, and may remain for many years, increasing sometimes to so great a size that the parenchyma is absorbed to make room for it: and when the calculus is not very large, by keeping up irritation and an increased flow of arterial blood to the organ, it often leads to an

augmentation of its glandular substance. A considerable calculus in the pelvis brings less danger of obstruction to the passage of urine, than of acute inflammation, which arising in one kidney, often affects both and creates fatal suppression of the urinary excretion: in the absence of acute inflammation, a calculus in the pelvis creates a dull heavy pain in the loins, extending sometimes to the scapulæ, at others over the buttocks or to the groins and scrotum, and along the thighs: bloody urine after exercise: dysury and frequent micturition as if there were a stone in the bladder: and by chronic inflammation of the membrane lining the cavities of the kidney, an abundant catarrhal or muco-purulent secretion is formed which appears with the evacuated urine.”

Leaving for the present the consideration of the phenomena dependant on the presence of calculi in the bladder, which, if the course of the canal had been taken, would have next demanded attention, Mr. Crosse passes, in chapter 5th, to the subject of urinary calculi situated in the urethra, and of calculous concretions in the prostate gland. In these cases the calculus, when yet very small, passes from the bladder, becomes fixed in the commencement of the urethra, increasing there in process of time to a considerable magnitude, so as to lodge partly in the prostatic portion of the urethra, and partly in the bladder. The best mode of ascertaining this state of affairs is the examination with the finger *per anum*. The symptoms are, for the most part, much more severe when the stone lies partly in the neck of the bladder and partly in the prostatic portion of the urethra. But when it occupies the prostatic or membranous portion of the urethra alone, and without extending into the neck of the bladder, it usually creates less urgent symptoms, and may remain there for many years without seriously affecting the health. Sometimes, however, the contrary is the case, and the author gives an instance to prove it. To remove a stone in the membranous urethra, we should endeavour to get the finger beyond it, push it forwards in the perinæum, and remove it by a semilunar incision.

The remaining attractive portions of this chapter we give in the words of the text:—

“Calculi lodged in the urethra, even of large size, are sometimes not discovered with the sound or catheter, which it seems difficult to explain, unless we suppose

the operator, thinking only of the bladder, neglects the slighter impression conveyed by the stone in the urethra: it may however happen that the muscles about the urethra, embracing firmly the instrument, prevent its touching the calculus, which is generally lodged in a depression or cavity, formed by it and answering to its size.

"Large calculi lodging in the membranous portion of the urethra sometimes work a spontaneous cure by finding an exit at the perinæum, the soft parts ulcerating or sloughing, or abscesses forming so as to let the calculi into their cavities. A boy, aged seventeen, after suffering for above ten years from very painful symptoms, and having abscesses and fistulous openings in the perinæum, got rid of a calculus in this direction, weighing two ounces and a quarter and measuring nearly four inches in length; it is now in my collection: the boy lived two years afterwards, voiding other smaller calculi by the wound, which never healed.

"Sometimes calculi in the urethra, quitting that passage by ulceration or otherwise, and getting into the cellular tissue under the integuments, descend into the scrotum, and still maintaining a channel of communication with the urethra, so that the urine gets access to them, they increase to an immense size; I am acquainted with a case where a calculus weighing eight ounces was removed from the scrotum of a man thirty-six years of age, and which I conjecture to have been formed in the above manner. The removal of such concretions is a very easy and safe operation; they are probably always composed externally of the phosphates, and if the explanation I give be correct, the cavity in which the stone is lodged will be found to communicate by a fistulous channel with some part of the urethra."

"Concretions of another sort about the neck of the bladder ought to be noticed. In aged persons, particularly with hypertrophy of the prostate gland, a bladder diseased, and the veins about it and about the rectum varicose, concretions of phosphate of lime, varying in size from a pin's head to a kidney-bean, are often found in the veins; sometimes they present the appearance of a white pea, as in fig. 6, (b) of plate ii, and an inequality or projection is observable (c) answering to the surface by which the body adhered to the coats of the vein. These concretions have no connexion with the urinary or any other excretions, and should not be regarded as calculi; they are a morbid growth from the coats of the vein, to which at an earlier period they are invariably adherent, and a membrane covers them, upon the surface where not adherent, which I presume is the extended inner coat of the vein, and the morbid growth originating in the outer coat. Fig. 6, (a) of plate ii, shews

a portion of vein containing one of these concretions, and d, e, f, g, exhibit them of different shapes and size; their chemical composition is chiefly phosphate and carbonate of lime, and they approach nearer to ossifications than to calculous concretions. I remember that Professor Meckel has well represented them, but know of no English author from whom they have received the same attention."

The author is remarkably brief on the subject of calculi in the urinary bladder, and their pathological effects, in the 6th chapter: his apology may be ours, namely, that the whole is familiar to all surgeons.

Chapter 7th is on sounding for a stone in the bladder. By sounding, the author not only means the introduction of an instrument through the urethra into the bladder, but "all collateral methods of gaining information, not only of the presence of a stone or stones, but their size, situation, mobility, and texture." Here, again, the author lauds the examination *per anum*, and says, "I have known so much mischief arise from the undertaking of operations for stone, without previously examining the rectum, that I am induced to represent forcibly the propriety of doing it in every instance: I should deem myself as little justified in omitting this method of exploration, as in operating without having sounded at all."

In the 8th chapter, the removal of vesical calculi through the urethra is treated of. After stating the occasions on which this operation is admissible or advisable, and the symptoms that are to lead us to a knowledge of the existence of such occasion; after also describing the introduction of the urethras vesical forceps, the author proceeds to give these practical suggestions.

"If the stone, fairly grasped by the forceps, can be brought into the urethra, it will in general pass readily through the prostatic portion of this canal, which offers the least resistance of any: and when it arrives in the membranous part, you may feel it *per anum* with the left forefinger, and if of considerable size, you can press it forwards, supporting it and preventing its slipping from the grasp of the blades: if very large, you may not be able to bring it any further than the membranous part of the passage, in which case, rather than make violent attempts to do so, you should extricate the forceps from it, and keeping the left forefinger curved beyond it *in ano*, press it forward in the perinæum, and cut upon

it by the gripe or Celsian method, or by a lateral incision, as in lithotomy. If the calculus can be brought into the spongy part of the urethra, it has escaped the resistance of the most powerful muscles and also of the triangular ligament, and can be carried on to the orifice: I have, however, been obliged to cut calculi out, not only at the perinæum, but just anterior to the scrotum, finding it impracticable to bring them further forward, on account of their size, or having allowed the forceps to slip off and being unable to re-apply them. Under some circumstances, where you cannot get the calculus further onward, you may be glad to push it again back into the bladder, reserving it for an early future trial: but where practicable, it is better to cut the calculus out at once. Sometimes a stone, which has been readily made to traverse the rest of the urethra, cannot be made to pass the narrower and firmer orifice: when difficulty is experienced in this situation, rather than persist in using great force, it will be proper either to crush the stone, or to make an incision for its exit just behind the external orifice, whereby the patient will be spared much pain.

Of lithotrity and lithotripsy, Mr. Crosse says little beyond an approval of those operations. He thinks that the lithotriptic percussor very recently introduced to notice possesses many recommendatory qualities, and "promises to be ultimately employed by most surgeons of experience." He alludes to the instrument constructed by Weiss, and used by Baron Heurteloup.

After this lengthened notice we can only mention the subjects of the three remaining chapters of the Treatise: chapter 10th, including the operation of litho-cystotomy; chapter 11th, being some remarks upon the treatment required after litho-cystotomy; and chapter 12th, treating of hæmorrhage after that operation.

The Appendices, three in number, contain cases of litho-cystotomy (of which there are twenty-two), tables of results of the operations of litho-cystotomy and a very full bibliography of gravel, stone, and lithotomy, extending even to individual memoirs in British and foreign periodicals.

The plates are twenty-nine in number, and have the same arrangement as the letter-press, that is, commencing with the kidney and ureters, then proceeding to the urethra, and lastly shewing the morbid anatomy of the bladder. As works of art we cannot say much for them; uncoloured, they

are stiff and harsh, and the colouring is altogether unworthy such a work. Still they may be held to be faithful representations of those changes of which the calculous concretions are either a cause or a consequence. As a practical work it deserves and we hope will have, the hearty support of the profession. It has already received the approbation of a body well able to judge of its merits—the Royal College of Surgeons—being the Jacksonian Prize Essay for the year 1833.

—o—
On Dentition, and some Coincident Disorders.
By John Ashburner, M.D., &c., &c. 12mo., pp. 235. London, 1834. Longman and Co.

The Gums, with late Discoveries on their Structure, Growth, Connections, Diseases, and Sympathies. By George Waite, M.R.C.S. 12mo., pp. 160. London, 1835. Longman and Co.

A vast deal has been written on dental surgery during the last few years, a great many volumes of all sizes have appeared, and these may be classed into good, bad, and indifferent. It is not easy to refer those before us to any one of these classes. Both the writers are entitled to some merit in directing attention to the influence of irritation of the teeth or gums as a common cause of constitutional derangement. Every physiologist will acknowledge the truth of this doctrine, and every pathologist may illustrate it, by the fact that a slight wound on a finger or toe may induce tetanus—that disease in any part may disturb the functions of the entire body.

Both these works are worthy of attentive perusal.

Dr. Ashburner, it is true, appears to ride a hobby; he can find the cause of a thousand and one disorders in the gums, just as Abernethy did in the stomach; but, nevertheless, both are perfectly right: as irritation in either part would, like irritation in any organ in the body, derange the whole economy. Dr. Ashburner has compressed a great deal of instructive information into a small compass.

Mr. Waite, has given the anatomy and physiology of the gums and teeth, and also a valuable lesson to mere mechanical dentists. He shews the importance of the teeth to the nutritive process, and the evils caused

by the irritation excited during their development; the fevers, convulsions, the congestion and hydrocephalus, the diseases of the lungs, intestinal mucous membrane, abdominal glands, cutaneous affections, &c., &c. He also adduces many facts to prove that the condition of the gums influences the soundness of the teeth, which every well-informed medical practitioner will acknowledge; as also that without attention to this indubitable fact, all operations will and must fail. We fully agree with our author, and are bound to state that his labours deserve the consideration of the profession. Mr. Waite's work may be perused with advantage by the general as well as the medical reader.

—o—

The London Anatomist; or System of Anatomy, Physiology, and Surgery, combined.
By G. D. Dermott, Lecturer on Anatomy, Physiology, and Surgery. No. 1, 8vo., pp. 94. Price 2s.!! Plate of the Superior and Inferior Extremities—coloured.

THE author of these works is known to the medical world, as one of the best teachers of anatomy in this metropolis. His numerous works and anatomical plates are too favourably known to require our eulogium. He has for many years past been a very popular lecturer, during which, he has given a most scientific view of the sciences upon which he now writes, and has consequently had crowds of pupils. The work before us, which is only a part of a voluminous one, bears internal evidence of the ability of its author. The arrangement adopted is the very best—the anatomy, physiology, and surgery of the human body. It may be objected, that we are too favourable to it; but we answer, that we have for years adopted a similar arrangement in our own lectures, as we believe it to be the only rational one in teaching the practice of medicine in all its branches. We hold it essential to inform our pupils of the anatomy or structure of an organ, of its physiology or functions, of its pathology, before we describe the nature and treatment of its diseases. It would, in our opinion, be absurd and useless to describe diseases and their treatment—indeed students could not comprehend them properly, unless acquainted with the anatomy and physiology of organs. It is always to

be recollected that elementary lectures are delivered to those unacquainted with science; that scientific terms must be explained, or they cannot be generally understood; and therefore, expletives are essentially necessary, as they enable every individual of a lecturer's class to understand him clearly. His auditory are too often composed of many individuals who have had a superficial, or indeed no preliminary education—no knowledge of those languages from which scientific medical terms are derived, and consequently such persons could not understand any medical lecturer, unless he gave the explanation of the more difficult, nay, of most of the terms he is compelled to employ.

It will be admitted by those conversant with science, that the most natural course to adopt in teaching anatomy and surgery, or medicine, is first to describe the structure of each organ, then its function or use, and then its diseases, whether medical or surgical. This plan has been already adopted by Mr. Bransby Cooper, in his excellent lectures on anatomy, physiology, and surgery—a work we were the first to praise, and which will speedily re-appear in a second edition. Whether Mr. Cooper or Mr. Dermott first followed this arrangement in lecturing we know not.

The nature of the work before us precludes the possibility of a lengthened review in a weekly medical journal; because to do the author justice, it would be necessary to quote several pages, which our limits do not allow. Thus the first twenty pages are devoted to the following subjects:—general properties of bones; the forms of bones; chemical composition; structure and growth of bones; organization; re-union of bones; and diseases of bones. Were we to do the author justice we should extract the whole of these articles, which would fill two-thirds of our space. We shall, however, give a specimen of the work, but strongly recommend our readers to peruse and possess the original. The student and the practitioner will find it of great value, and its remarkable cheapness is another recommendation.

The author, after describing the physiology of the periosteum, alludes to the vessels that secrete bone and effect its re-union.—

“When a bone becomes dead, most fre-

quently the dead portion or sequestrum is encased within the new formed living bone, and being lessened in size by the action of the absorbents, is loose within it. All these facts show the importance of the periosteum in the production of bone.

"The doctrine of Duhamel was opposed by Haller and Dethleef; they maintained that the gelatinous fluid, which is to become the cartilaginous nidus, is not produced by the changed or altered periosteum, but merely extravasated from the extremities of the fractured bone, and in a particular manner from the medullary membrane. If a living bone is pierced and the membranes of its marrow are destroyed, the old bone dies and a new one is formed from the periosteum, which will encase the dead. If, however, the operation being reversed, the periosteum is destroyed, but the nutritious vessels of the bone and the membranes of the marrow are left entire—the new formed bone will be secreted by these, and will be contained within the old—the dead forming the encasement. Bone is also frequently deposited in the centre of cartilage, in the natural process of ossification. So that it may be produced from any part of the vascular system of the bone—either from the vessels in periosteum—the membrane of the marrow—or the substance of the bone itself.

"During the first stage of re-union, from the first to about the tenth day, there is extravasation of blood, and a swollen and reunited state of the periosteum and soft parts around the fracture. About the tenth day the redness has disappeared, the blood is absorbed, and the effused lymph is coagulated. The second stage extends from the tenth to the twenty-fifth day; during this stage the lymph effused externally to the fracture and the original swollen periosteum become cartilaginous and then osseous, so as to form the osseous clasp or hoop of Duhamel; while a similar internal clasp is forming from the membrana medullaris, and either partially or totally, for a time, blocking up the internal cancellous cavity of the bone; and whilst the principal permanent part of the process of ossification is only about to commence.—The bone during the whole of this stage is still somewhat flexible. The third stage extends from the twenty-fifth day to the end of the sixth or eighth week; during this time the external and internal bony clasps become more ossified and inflexible; but the solid ends of the fractured portions do not accept of an osseous union. During the fourth stage, which lasts from the sixth or eighth week to the end of the fifth or sixth month, the bony clasps become completely ossified and inflexible, a new periosteum is formed from the surrounding condensed cellular membrane, the continuity of the membrana medullaris is also restored, and

the ends of the bone become united by osseous matter, so that a trace of the previous solution of continuity is scarcely distinguishable. During the fifth stage, which reaches from the fifth or sixth month to the twelfth, the direct union between the extremities becomes consolidated and very strong, whilst the two provisional clasps are absorbed, the irregularity of the surface of the bone becomes removed, and the medullary canal restored. Should, however, the two ends of a fractured bone not be brought into just apposition, but touch each other laterally, then the provisional bone or callus becomes the definite medium of union.

"Any artery in the body may assume such a diseased and altered action as to produce bone; which is thus formed where it should not be, in the tendons, joints, the great arteries and their valves, the flesh of the heart itself, and even the substance of the brain: however these are mere depositions of inorganic calcareous matter, and are not fibrous—this process is therefore generally called false ossification.

"Observe that bone is prepared, and separated from the blood, by a vital action of the vessels belonging to the osseous system, or just as the actions of the system, as a whole, assimilate the aliment to its nature by a living process, and so find material for the growth and waste of the body—so these less systems (of which the osseous is one) by their specific, living actions, build up their own structure—from the material or from the blood thus produced; and these by their combination of action, constitute the animal economy."

This extract enables our readers to estimate the manner in which this work is executed; and we can assure them that the whole is equally concise and comprehensive. In conclusion, we cannot refrain from expressing our favourable opinion of the coloured plate of the arm and leg just published by Mr. Dermott. This illustrates the vessels, nerves, and muscles of the parts just mentioned, and will be a great assistance to the student and operative surgeon. It is evidently copied from nature.

Foreign Medicine.

Cold Water in Surgical Diseases.

M. BERARD, in a paper on this subject, after citing numerous cases, comes to the following conclusions:—

1. Cold water, topically applied, should be made to act in an uniform, continuous manner, and until no fear remains of inflammatory action; irrigation by one or more capillary syringes is most effectual; wet cloths are less so.

2. Continued application of cold water is an infallible means of preventing and combating inflammation in the worst cases of traumatic lesion, as in those of bullet wounds, crushing weights, those from the dissection and extraction of cysts situated among the tendons of the hands, &c.

3. Gangrene is the only thing to be feared from long-continued irrigation; when it supervenes it is not in the wound, but the parts around it, and comes on when the whole of the circumjacent parts have been bruised and disorganized by violence; it is caused by the obstacle opposed by the cold water to the free circulation of blood.

4. M. Berard has had no opportunity of using cold water after amputation, but he firmly believes that it would prevent most of the local and general accidents which the operation too frequently induces, and would also favour union by first intention.—*Archives Generales*, January 1835.

—o—

Immense Osteosarcoma of the Lower Jaw, disarticulation of the right half of the Bone, with dissection of the ulterior and right lateral portions of the Pharynx.

M. Beau, 24 years of age, had been in perfect health up to the end of 1832. In consequence of an irritation caused by the decay of the last but one molar tooth of the right lower jaw, an inflammation and suppuration of the cheek came on, and several abscesses in succession formed, although the presumed cause of the mischief, the tooth, had been extracted. The alveolus remained fistulous, and to make matters worse the wisdom tooth began to grow; for this a scarification was made. Five months passed, and the fistula then cicatrized; but immediately afterwards another succession of abscesses opened externally on the same cheek, leaving an inflammatory congestion against which antiphlogistics were used. It was, however, never entirely reduced, and after about six months there still remained a small hard and indolent tumour towards the angle of the jaw. Meantime the alveolar edge of the bone was undergoing changes of the most serious kind. As before stated, a scarification of the gum had been made. From the edges of the wound and the alveolar fistula some vegetations proceeded, which now began to annoy the patient. Fomentations of the cheek made them rapidly worse, and the inflammation of the parts visibly increased. Nothing particular passed and the progress of mischief was very gradual up to September, 1834, at which time the patient came to Paris to place himself under the care of M. Lisfranc.

At this time an immense congestion of the right side and lower part of the face was observed, extending below the middle of the throat behind, covering the carotid, as far as the upper part of the sterno-mastoid muscle; the lobe of the ear was pushed backwards,

and the tumefaction was gradually lost towards the zygomatic arch; anteriorly it reached the angle of the chin and the middle of the lips. The skin was sound throughout, but adhered in the centre to indurated subjacent tissues. It was difficult to tell the extent of mischief within the mouth, the swelling rendering the opening of the mouth impossible. However, a hard, smooth, and whitish tumour was seen approaching the centre of the lips, and pushing the tongue to the opposite side. This tumour originated from the back part of the right lower jaw, but it was a question how far back it extended, and this could only be ascertained by the finger. In order to obtain a sufficient opening of the mouth for this purpose, M. Lisfranc first attacked the outward inflammation surrounding the temporo-maxillary articulation, and meantime placed a wedge between the teeth. In reducing this congestion M. Lisfranc had two motives: one, to facilitate the examination of the mouth, and next to free the carotids so as not to implicate them in the operation; if the worst happened they must have been previously tied.

The tumour was sensible to pressure, and painful; the skin hot and discoloured. Emollients and 12 or 15 leeches repeatedly applied, were employed to it. M. Lisfranc advises in such cases to place the leeches two inches from the tumour: applied immediately upon it, they often increase the irritation.

As the irritation disappeared the skin became moveable on the tumour, the jaws daily became more open, and the congestion became circumscribed. After three weeks the finger could be introduced, but with difficulty. The swelling, however, though reduced, still persisted along the fore part of the carotids, and as it passed to the chronic state, hydriodate of potash, cerate, and compression were used. In this manner in a few months the swelling was sufficiently reduced to free the angle of the jaw and the carotids. But during the progress of this external treatment, the tumour within had vastly increased: it filled almost the whole of the mouth, pushing the tongue against the left cheek, and passing backwards to the entrance of the pharynx, so as to render the respiration difficult. The speech was unintelligible, and the deglutition exceedingly painful. It became, therefore, an urgent necessity to withdraw this enormous tumour, the more as a diarrhoea came on, caused no doubt by the ingestion the morbid secretions of the tumour and mouth. For the rest, the patient was in good health, and strongly insisted on the operation. Before deciding on it, the finger was introduced into the mouth, and discovered that the pharynx was not involved but simply joined to the tumour: the palate was nowise changed.

An incision, commencing at the edge of

the lower lip, three lines on the outer edge of the median line on the right side, descended perpendicularly to the lateral and middle parts of the larynx, turned around the tumour as it proceeded outwards, and passed upwards anterior to the carotids, then along the posterior edge of the ramus of the jaw, and finally terminated in a line with the auditory foramen, a small distance anterior to the temporal artery. This vessel was guarded by being marked by an assistant. The skin and subcutaneous cellular tissue were comprehended in this incision. The dissection of the flap was made from below upwards; the skin was found sound, only thinned by the distension of the tumour. The canine and second incisor were extracted, and at four lines on the side of the symphysis menti the body of the bone was sawed through. It should be understood that at the point chosen for the section the soft parts had been carefully incised. Detaching then this tumour anteriorly and inferiorly, partly with the bistory and partly by tearing, according to the strength of the adhesions, the branch of the jaw could be sufficiently separated to obtain a certainty as to the state of the bone and the connections of the tumour about the pharynx. The erosion of the bone in the mouth extending anteriorly as far as the first molar tooth, and posteriorly towards the internal surface near the angle of the jaw, it was decided that the bone should be taken away, the more as the altered tissues extended into its very substance. In the middle it was so confounded with and lost in the centre of the tumour, that it was impossible to separate them. Towards the pharynx M. Lisfranc ascertained that the tumour was merely joined to the latter, and did not involve its structure. M. Lisfranc detached below circularly; behind and before the carotid he separated with his finger, or divided with scissors the more resisting cellular bands, whilst an assistant's fingers covered the vessel and pushed it behind and outwardly.

Sure of the carotids, M. Lisfranc returned to the fore part of the tumour. Superiorly the tumour adhered so strongly to the anterior pillar of the arch of the palate that he found it necessary to sacrifice it; then continuing the ablation from above downwards, and before backwards, he examined the connections of the pharynx, which he perceived adherent to the tumour by its anterior and lateral part, and was drawn along with the tumour when the latter was moved. It was therefore necessary to dissect it carefully from above downwards, for at least the extent of three inches. Midway in this space the small muscles arising from the styloid process were found pushed back to the pharynx. The tumour being thus detached, the disarticulation only remained. The section of the pterygoid muscles was easily effected, but that of the tendon of the temporal above the coronoid process was exceedingly diffi-

cult. This process, by an anomaly that made it approach the formation of carnivora, rose as high as three lines above the condyle, being only separated from it by scarcely six lines; so that it was deeply situated under the zygomatic arch and near its base. The bony parts were in such close apposition that if the blade of a bistory were introduced, all movement was impossible. Then cutting the uniting parts of the temporo-maxillary articulation anteriorly and outwards, and drawing downwards, the coronoid process was gradually lowered. The remaining section was then more easily effected. Five or six arteries were tied: the lingual was the only one of any size.

During the operation the tongue was kept in its natural position. Previous to dissecting the pharynx, M. Lisfranc got rid of a great part of the internal portion of the tumour, premising the section by a ligature round the whole, in order to be à l'abri of any great hæmorrhage. He then waited for a short time for any hæmorrhage that might occur. In operations where flaps are to be re-applied and maintained by sutures, too much attention cannot be given to the prevention of consecutive hæmorrhage. Were it to come on it would necessitate compression on a flap in which the circulation is already at a low ebb, or even the removal of the sutures and their after re-application—consequences pregnant with inconvenience.

The flap was retained by numerous stitches. From the edge of the lip to the chin the twisted suture was preferred, in order to the better apposition of the surfaces and the giving to the inflexions of the corresponding integument. These ends were so well obtained that it was necessary to search for in order to find the point of union in the lips. In all the other parts of the wound numerous cut sutures were applied. At the lower part of the wound the skin formed a little hollow cul-de-sac looking downwards; this sinus, retaining pus, might facilitate its infiltration into the circumjacent lax filamentous tissue. A small longitudinal incision laid bare the cul-de-sac, which was left open as a mode of exit for pus. A large compress well covered with cerate, a thick layer (plumasseau) of lint to keep the flap gently applied to the subjacent parts, long compresses, and a chin bandage, constituted all the dressing.

By means of a tube, introduced as far as the base of the tongue the patient was enabled to drink. Deglutition, which was somewhat impeded on the following morning and the third day after the operation, in consequence of the traumatic inflammation, has been since perfectly easy. All has gone on well, and with remarkable rapidity. On the third day after operation the patient could sit up several hours; on the fourth he walked about his apartment; the sixth he went out on the boulevard; and on the tenth he came to La Pitié, where M. Lisfranc

shewed him to his pupils. He speaks much more clearly than before the operation; indeed he spoke tolerably well three days after that event.

There remains a paralysis of the face, and a partial one of the orbicularis palpebrarum: the patient can cover about two-thirds of the eye-ball. A portion of the lingual nerve was taken away with the tumour; during the section he felt a kind of vibration in the opposite half of the tongue, and he still feels it. Notwithstanding the loss of this nerve he retains the power of distinguishing tastes, on that side of the tongue.

The tumour was found to be at least four inches in the diameter of every direction. It was composed of a white, elastic tissue, similar to the fibrous polypi of the uterus. At its middle part it surrounded the bone, which, without giving traces of inflammation or ulceration, was worn and destroyed. The tumour seemed to arise from the periosteum of the degenerated alveoli; at its posterior part a portion of the lingual nerve, with some muscular fibres cut away with it, were observed.—*Gazette Medicale, Feb. 7, 1835.*

—o—

Universal Remedy—Brandy.

An unfortunate and apparently crack-brained French mechanic, named Guillaume, has taken it into his head to address a memoir to the Minister of Public Instruction, stating that he has found a remedy for every possible disease, in brandy. The memoir (presented 1832) was referred to the Académie de Médecine, who very properly took no notice of it. But M. Guillaume was not to be so silenced: he writes again to the Minister and the Academy; upon which a committee of the latter "proposes to reply to the Minister, that this piece of scribbling being altogether astray from the most simple and received notions of physiology, of medicine, therapeutics, grammar, style, and orthography, is unworthy, in any point, of further attention."

To give our readers an idea of the grammar and style, we extract the following:—M. Guillaume announces, that he is acquainted with "*l'imperfection de l'art de la médecine, qui cependant est celle qui aurait dû être portée au plus haut degré de perfectionnement, même jusqu'au point de prolonger l'existence de l'homme, et de ne cesser de vivre que par vétusté ou par accident ! !*"

—

Fracture of both Jaws.

A miner fell into a sort of pit, his mouth pitched upon a large wooden stake, and both his jaws were broken. These fractures, complicated with contusions and lacerations of the soft parts, were so directed, that the dental arches bent inwards were as if separated from the body of the bone. The upper jaw being reduced and maintained in situ consolidated very well. The lower one—

being only adherent by a thin slip of the gum, was taken off together with the six teeth it supported. The patient recovered, but remained with an infirmity that deprived him in great part of the power of speaking and chewing.—*Memoires de Clinique Chirurgicale, by M. Vallat.*

The London Medical

AND

Surgical Journal.

Saturday, February 28th, 1835.

—

REFORM IN THE COLLEGE OF PHYSICIANS.

WE had occasion, in a late number, to congratulate the Medical Gazette on the increasing liberality of its principles. If we were joyful then, we are now absolutely in raptures, and feel a Peri-like satisfaction in flying up to the Paradise of medical reform with the sweet tears of our repentant brother. The Gazette of February the 14th announces, not with a cold and ungracious assent, but with a glow of generous enthusiasm, a real reform "and no mistake" in the College of Physicians. They have actually agreed to abolish *in toto* the orders of candidates and inceptor candidates; they have consented that a degree from either of the English Universities shall cease to be acknowledged as a passport to the fellowship; they have determined that the alumni of Oxford and Cambridge shall take their place among the licentiates with the graduates of Edinburgh and Paris; they have made every licentiate of thirty years of age and four years' standing, eligible to the fellowship; and they have thrown open their doors to all men who have received a certain specified education, even though they may not have a medical degree. We think they might as well have let this last piece of liberality alone, as long at least as they continue to be merely a College of Physicians—a doctor without a degree is a kind of walking bull; our friends in Erin would

be apt to compare him to a gold-headed cane without a gold head—but let that pass. “If they do all this,” says our contemporary “and we assert that they have agreed to do all this—surely it will be admitted by every candid person that a prodigious step has been made in the good cause.”

C'est superbe! We really can hardly believe our senses; the thing seems too good to be true; yet our contemporary says it is so, and he “is an honourable man, and they are all—all honourable men.” We only wish that he had given us some pledge to make us quite certain of it; now if he had but staked his *reputation for consistency* upon it, we should have straightway banished every doubt, and resigned ourselves to all the luxury of joy.

We must not, however, be faint-hearted, the good cause will triumph; indeed it cannot fail, seeing that the *bad cause* has given up the ghost—where are its supporters? “an echo answers where are they!” Sir Harry is turned leveller, and the green journal cries *vive l'égalité!*

Our friend comments so admirably on the above-mentioned salutary mutations, that we “turn up the white o’ the eye to his discourse;” the only point on which we disagree with him, and that fortunately is not a practical one, is the motive from which these spontaneous reforms have sprung. He speaks of “the liberal spirit which seems to have prompted them”—now God forgive us, as William Cobbett would say, but we do firmly believe that there is not an iota of liberality in the whole transaction, and that Sir Harry and his merry men are simple antitypes of the beaver who bit off his tail. No matter however for motives; the cleansing tide of reform is rushing through the Augean stable of Pall Mall, and all the *fellows* have brooms in their hands trying who can sweep the hardest; we have only to say *macte virtute!* We now turn our eyes in another direction and ask what

the *twenty-two* of Lincolns Inn Fields are about? Will they too exhibit a few amiable traits of “spontaneous” liberality, or will they die game? Will they, like the fellows, judiciously bear a hand in sweeping the stable, or will they fatuously wait to be themselves swept with a besom of destruction?

We hope they have instinct enough left to avoid the latter insane line of conduct.

“Dii, prohibete minas! Dii, talem avertite casum!”

As for the *Rhabbarbarians* of Blackfriars we cannot discern a ray of hope for them. To recommend them to reform would be tantamount to advising them to expunge themselves from the face of creation, since, where a thing is an unmixed nuisance, reform and annihilation become synonymous. We would not advocate suicide, but could they not find out some gentle way

“to win
Oblivion, and melt out their essence fine
Unto the winds?”

Verily, if they devise not some “spontaneous” mode of extinction, we predict, in the Oriental style best suited to prophecy, that they will be pounded in the mortar of destruction with the pestle of scorn.

—o—

MEETING OF THE MEDICAL PROFESSION AT LIVERPOOL.

For some time the medical gentlemen of Liverpool have been anxious to establish an institution by which they would all be connected in one general bond of honourable and efficient union. Accordingly, last December, a circular was addressed to the profession, acquainting them that a preliminary meeting had been held, at which it was unanimously resolved—1st, “That it is highly desirable that an attempt should be made to raise a sum of money, by subscription, sufficient to erect a building for the future reception and preservation of the Medical Library, with commodious rooms for a Museum of P.athological Anatomy, and for a Lecture-room, and apartments for a resident librarian.” And, 2ndly, “That an address be presented to the committee of the Royal Institution, requesting their permission to erect the proposed building on part

of the vacant ground belonging to and opposite to the Royal Institution, Colquitt-street." The circular added, that the contemplated building was intended "for the sole use of the profession."

The handsome sum of upwards of £600 was subscribed since the project was set on foot. Dr. Rutter, with a liberality which reflects infinite credit on him, put his name down as the donor of £300.

Agreeably to notification, (also by circular), requesting the medical gentlemen of Liverpool to meet at the Royal Institution, in Colquitt-street, on Tuesday, to take into consideration a communication from the president of that institution, respecting the erection of a building, &c., about 40 or 50 members of the profession assembled on that day, in the Lecture Room of the Royal Institution. Shortly after 3, p. m. Dr. RUTTER took the chair, and opened the business by stating generally the object for which the meeting had been convened. An address to the Royal Institution's committee had been delivered and laid before it. President Brooks read the communication to the committee of the Royal Institution, who regretted, as it was expressed, their inability, at that time, to recommend to the proprietors any steps—the annual general meeting of proprietors not being summoned until Friday, the 13th. A written communication from President Brooks was, however, transmitted instead of a former verbal one. It contained a general statement of the terms conformably with which the committee of the Royal Institution felt disposed to make a grant of land, on which a building for general medical purposes (such as holding public meetings, &c.) might be erected. This offer on the part of the institution's committee was, however, conditional, and in effect—that any such medical buildings, with the museum and property therein contained, should become the property of the present Royal Institution; but that the economy or management of such proposed building should be by a committee of medical gentlemen. Further, that the proprietors of the present Royal Institution should claim and possess right of *entrée* at specified hours, together with power to introduce non-residents at will. The apartments to be open to professional men without any controul on the part of such Royal Institution proprietors, &c. It was evident, that in these conditions there were advantages and disadvantages, 1st, On the score of advantages, they could have land for nothing, and, if the proposed terms were acceded to, permanence and security also. 2d, As to disadvantages, there was an absolute surrender of independent right in such property, including the pathological museum, &c. And if, for instance, at any future time, the removal of such moveable property should be considered expedient, or desired on their part, such removal would

be impossible, according to the tenor of the conditions named. And further, no mortgage could be effected on such building or property, &c. Upon an expression of the opinions of the meeting being requested,

Dr. CARSON, sen., rose and remarked, that, as he intended to say very little, he would observe that, in his opinion, the really important matter for the meeting and the medical profession to consider was—to raise a sufficient sum of money. How much would be required he did not know; but as to the mode of raising it he would say, if there were any other than that pointed out by the committee of the Royal Institution, then that other should be at once preferred. It would be better that the profession have land of their own than accept a grant of any which would so fetter them, and interfere with their future arrangements, which should be unconditional. Taking for granted, that a given sum was necessary to meet the expenses incurred by erecting a building for the use of the medical community of Liverpool, and that the whole of such sum could not be met by subscriptions from the profession, and donations from those liberally disposed, further funds could be forthcoming by effecting a mortgage. But money could not be raised by mortgage, if the proposed medical institution were connected, on such conditions, with the present Royal Institution. There were many other matters of only minor moment in appearance, which nevertheless, by him, were viewed differently. There were the mode and terms in which their property would be conveyed *legally*, to be considered. This would be a point involving many difficulties. Supposing, however, that the conditions named in the document before the meeting, from the president, on the part of the Royal Institution's committee, were accepted and gone into, what security, he would ask, would the medical profession have for their property? The Royal Institution itself might become insolvent. (*Hear, hear—Oh, dear no!*) He made such an allusion as at least a *possible*, if not a *probable* occurrence. To pass to still more subordinate matters, the proprietors of the Royal Institution were to have permission to introduce visitors and possess tickets for themselves. There need be no objection to that, provided such proprietors' tickets were not transferable; for if so, the result, need he say, would be injurious in many ways. The conditional grant of land stipulated farther, that the articles lodged in the proposed new institution should also be inalienable property! He (Dr. C.) really could not see why such a stipulation as that should be made. Conditions went far enough, if the building was to be virtually the property of the Royal Institution. Articles admitting of being removed should not be held inalienable. Advantages there might be in being connected with the Royal Institution; but there were many disad-

vantages. If any connexion whatever was made, which he thought should be avoided, such association of interests should be founded on mutual advantages, not confining all of them to one side.

Dr. JEFFREYS, on presenting himself to the meeting, cast his eyes at the empty benches, and regretted much that the attendance of medical gentlemen was so very inconsiderable. He regretted this, for as much as the object of the present meeting involved a subject upon which the feelings of the whole resident members of the profession must, more or less, be strongly interested. He thought that the wisest measure, without attempting too much at once, would be to proceed to appoint a committee from the body of those present, with instructions to consider the matter over, and collect as much information as possible respecting what would tend to advance the objects of the profession in their proposed new building, for their own general and particular purposes. Whenever such committee, as that proposed by him, considered themselves possessed of information of value, let a public general meeting of the whole profession be forthwith called by public advertisement. The present meeting consisted only of some forty or fifty gentlemen at most. Circulars sent out and addressed by any single individual must necessarily have overlooked many practitioners whose residences or practice lay in obscure parts of the town. Contributions in support of the proposed Medical Institution would, he doubted not, be afforded by many to whom circulars never had been issued, or, if issued, had not reached. Public advertisement would have precluded such impolitic oversights. The doctor next animadverted upon the document submitted to the meeting from the Royal Institution's committee: the advantages and disadvantages of accepting the offer of land had been alluded to from the chair, and by Dr. Carson. In his (Dr. J.'s) opinion, all the advantages was limited to the grant of land on which to erect a building; and in return for which "grant," there was, on the part of the profession, to be a virtual and absolute surrender to independent right in that property, fixed and moveable! The value of the grant was too petty—only some £240 or so—and what was that as a consideration? If there was, at length, to be an institution for the common benefit of the whole profession, it should be on a basis much more extended, and grants made on a much more liberal footing. As to making this and that property inalienable, neither the library nor funds accruing to it by yearly subscriptions could so be disposed of by any institution or set of men. Doctor Jeffreys here went into some episodal remarks at considerable length, touching the library and the state of its property. To a partial cry of "*Question, question,*" he observed that he would soon show the bearing of these remarks on the

question before the meeting to be sufficiently close. The difficulties on one side and another, in conducting and keeping up the Medical Library, which had been experienced by others present, as well as by himself, many years ago, would teach him to guard against such occurrences as were inseparable from mixed and conflicting interests, if he could prevent them, for the future. It appeared to him that really as little connexion as possible should be had with the present Royal Institution. Every one knew perfectly well with what high-sounding pretensions that institution had been blazoned before the public at a former period. Its partisans then maintained that it was to do this and the other thing. It was to vie with the most celebrated existing institutions in the metropolis; and outrival those of Dublin, Glasgow, and Edinburgh! But what had been the result? Shares originally £100 each, instead of having risen in value, had fallen lower and lower: they could now be had for 30 or £40. The profession could impart respectability to their proposed institution without being connected with the Royal Institution, which was a failing institution. It was not by money that any institution could be made respectable. Instead of its being desirable that the profession should covet connexion with the Royal Institution, the latter should truly rather feel eager to court the association of a scientific body like the medical profession, which would confer respectability on them. If "*respectability,*" which had been so much talked of, could only be procured by a junction with the Royal Institution—or, rather, if the profession had not an independent respectability—in his opinion it was premature, until it had, to propose a building for medical purposes. He, too, would remind the meeting of the necessity for being cautious and deliberate. They would be legislating not for themselves and existing generations, but for posterity. If there is to be any building, let it be one *sui generis* —peculiar to medical men. The corporation would, he doubted not, aid the profession in carrying into effect their public-spirited intension, when the time arrived. Dr. Jeffreys—after alluding to the great and confessed merits of the chairman, Dr. Rutter, the originator of the whole project, whose claims would be nullified if the conditions of the chairman of the Royal Institution committee were gone into—concluded by moving for the immediate appointment of a committee to consider generally what were the preferable means for effecting the objects desired.

Dr. MACDONALD entertained, so far, similar views, and would second Dr. Jeffrey's motion, which he did with pleasure. He thought it premature on the part of the present meeting, limited as to numbers, to come to any conclusion, or return a definite answer, other than a vote of thanks for their kind attention to the committee of the Royal

Institution. Such a meeting could not be considered as representing the opinions of the resident general profession. The meeting, too, was still in a very unprepared state. The price of a suitable space of land, apart from that offered by the Royal Institution, was unknown. The conditions on which the proposed "grant" were offered were, in his opinion, by much too partial—partial in favour of the institution, and much less liberal than he could have expected towards the profession. A new building, if erected, could not be called, or virtually be, the property of the profession. They would not be even allowed to remove at a future period, however the force of unforeseen circumstances might render it advisable, any moveable property lodged therein by their own industry, liberality, or zeal. He would give his support in favour of the appointment of a committee to gain information on all points; and also for a public general meeting being called, as early thereafter as possible, by public advertisement.

The **CHAIRMAN** thought it would be premature to nominate any committee for such general purposes, until the meeting had agreed how they should dispose of the conditional offer tendered by the Royal Institution committee. An answer was desired by that body, in order that it might come before the annual general meeting of the proprietors, as had been mentioned. He had only had Mr. Brookes's reply since Saturday last, and he (Dr. R.) lost no time in calling this meeting to decide upon it.

Dr. BAIRD viewed the conditions on which the grant of land would be made as very hard indeed. The proprietors of the Royal Institution would be the trustees of the new building, agreeably thereto. He contended that the predominance of the trusteeship should be centred in medical men. If subscriptions for a building upon liberal principles, and on an independent basis, were brought before the public eye, there could be no doubt of public support being forthcoming. The Medical School of Birmingham, on its own independent basis, met with handsome pecuniary aid from the non-professional public; and the public of Liverpool would be no less liberal and public spirited.

Mr. BLACKBURNE, so far as could be gathered from several wordy and tedious repetitions, appeared to be warmly in favour of accepting the offer from the committee of the Royal Institution. He could see no force in any of the objections offered, except, perhaps, to claiming a right to the property of moveables. With reference, however, to any such claim to property in the museum of morbid anatomy, provided no right was involved to deprive medical men of such property, he could see no objection to that. A properly drawn up trust-deed would be ample security. All that the proprietors of the Royal Institution seemed to

claim was simply, that ~~they~~, and none else, should be the owners and trustees of the property, legally considered. Had they even claimed, in the same spirit and sense, a right to the property of the medical library, there could be no objection but one of mere feeling, even to that. He at the same time had no objection to a committee after the chief question was disposed of, if then necessary.

Amidst a guerilla style of remarks from different gentlemen, while keeping their seats, the *ad interim* secretary to the Royal Institution observed, that the document read from Mr. Brookes must be regarded rather in the light of a communication from one private gentleman to another, than as an official intimation.—How this observation told upon the ears of the meeting cannot be stated. No comments whatever passed upon it.

Mr. CHRISTIAN here asked what was the sum of money which required being raised. Was there any information lodged with the meeting as to the plan, extent, and so forth, of the proposed building? Until the profession found where a check to their progress lay, they had better agree to let the proposal from the Royal Institution stand over, to be availed of or not, as might seem expedient at a future period.

Mr. C. BYRON echoed the words of Mr. Blackburne.

Mr. ROGERSON could confirm what had been stated as understood of the existence of suspicions, on the part of many, if the Royal Institution had any connexion or controul over the proposed institution. There were not only suspicions afloat, but a disposition to withhold their pecuniary aid or support in any way from the Medical Institution, if the committee of the Royal Institution should have any power over the property. It certainly would carry a strange appearance and impression before the public, if the profession were to permit their property to be vested by a trust-deed in trustees appointed by the proprietors of the Royal Institution. Surely the profession were competent to manage their own affairs, and take care of themselves.

Dr. ROGER SCOTT was against any final opinion being given to the proposal.

Dr. FORMBY here said—"Mr. Chairman, I have really very little to say at all: and, as I have been so short a while in the room, perhaps I ought to say nothing at all. But since I am upon my legs, I will observe, that if the profession can carry this work on by themselves, let them do so—provided they can. If they cannot, which is my opinion, then it will be as well that they connect themselves with the Royal Institution; for, unless so connected, the public at large will not support them in their undertaking." (*Hear, hear.*)

Dr. ANDERSON contradicted the last sentiments uttered by Dr. Formby. The public in general were not now likely to be biased

by the mere circumstance of any institution or those connected with one, supporting any proposal of intrinsic and independent merit.

The CHAIRMAN proposed taking the sense of the meeting, as to what reply should be returned to the Royal Institution's committee. Before this was done, at the suggestion of Dr. Thorburn, the conditions were again read distinctly aloud, several gentlemen having entered subsequently to the former reading of the document. Mr. Neill inquired if the Corporation would grant a sum of money as an equivalent for the surrendered use of that building, and if such sum (£1,000) would be gifted in aid of the proposed institution. It appeared from the Chair, that the Corporation had not been conferred with on the subject as yet.

Upon the sense of the meeting being taken, a committee of five was appointed to confer with the representatives of the Royal Institution, and to report generally upon the ways and means which would appear desirable; the result to be laid before a public general meeting, to be called by advertisement. Thanks being by acclamation, voted to Dr. Rutter, as chairman, the meeting dispersed.

Hospital Reports.

WESTMINSTER HOSPITAL.

Renal Disease.—Case of Wm. Hall, concluded from page 831 of our last Volume.

JAN. 22nd. Better than at last report. The colour of the urine is not of so deep a hue as before. His daily allowance of bread has been increased, and he is taking the following mixture:—

Rx. Quiniaz sulph. gr. viij;
Acid sulphuric dilut. 3j;
Infus rosæ co. ʒ viij.
M. Capt. coh. ij. ter die.

28th. His health daily improves; he is allowed to go out for about four hours in the middle of each day, for the sake of fresh air and exercise. The character of the urine continues to improve, although it remains somewhat of a lilac tinge, and continues to deposit the amorphous sediment in a less degree. The quantity passed daily is still about six pints, but of this the by far greater proportion is passed during the night.

Feb. 6th. The general aspect of the patient's countenance is evidently improved, though he still remains feeble and emaciated to a certain extent; he states that he daily gains strength, and that there has been latterly a partial restoration of the virile powers. He has now no remains of pain either in the lumbar or hypogastric regions. The tongue is still flabby and covered with a milky-like fur. The appetite is now so much improved, that he states he could eat far more than he is allowed. The pulse 96, full and

soft. The urine in quantity is as at last report, is rather paler in colour, and continues to deposit the lilac-coloured sediment. It now tinges the litmus-paper more decidedly of a red hue, most probably from the effect of the acid remedy which has been employed.

14th. Was put on "full diet" about the day after the date of last report. At the present time he is not nearly so well as at last report. The lassitude and debility from which he had in a good degree recovered, all now present, as is indicated by the countenance, &c. in almost as great a degree as the period of his admission. The indications afforded by the characters of the urine remain the same.

21st. He remains the same as at last report, and is continuing the same remedies.

24th. Left the hospital to day, in consequence of having the wants of a young family to attend to. He is much the same as at last report, on the whole, not having received much benefit. The urine, when tested with the litmus-paper, still shews an excess of acid.

Phlegmonous Erysipelas.

Hancock, aged 53, was admitted into Northumberland ward, January 18th, as a patient of Mr. Guthrie, having been previously ill eight days. He had an extensive ulcer of the leg, just above the ankle, which having been of very tedious cure, healed about two years ago. About a week or two previous to his admission, he grazed, accidentally, the surface of the old cicatrix of this ulcer, and the sore thus produced being neglected, it became highly inflamed and irritable, and gave rise to the erysipelas for which he was admitted. A spreading and superficial inflammation proceeded up the inner side of the leg and thigh, in the course of the absorbents, whose tissue was evidently inflamed. At the time of his admission, there was a perceptible tendency in two or three places, for the violence of the inflammation to exhaust itself in the formation of matter, and in the course of a few days, several patches of diffuse suppuration had become established in the subcutaneous cellular tissue, pretty much in the course of the absorbents, from the foot to the groin. From the time of his admission, the general symptoms have been those of an asthenic type, and have required a considerable degree of support and stimulation. The treatment ordinarily pursued in such cases was adopted, and the matter which we have spoken of, was liberated by means of incisions of moderate size (on the plan of Mr. C. Hutchinson), very judiciously instituted by Mr. Hancock, as occasion appeared to demand. Notwithstanding the greatest degree of care, symptoms of cerebral crethism appeared a few days since, which seemed at one time to threaten meningitis.

Feb. 3. There is a considerable degree of muttering delirium present; tongue dry, and covered with the brown fur of typhus; teeth and gums covered with sordes; pulse 65, small and feeble.

Mr. Guthrie ordered him to have daily four ounces of port wine, in addition to the same quantity which he has been allowed for several days, and likewise prescribed the following mixture.—

Rx. Quiniaz sulphat., gr. xvj;
Acidi sulphuric. dilut., 3 ij;
Tinct. cinchonæ, comp., 3 iij;
Infusi gentian. comp., 3 v.

Fiat mistura, cujus capiat cochl. duo amplas 4tis horis.

6th. Rather better; pulse 72, but still very feeble. Another incision has been made, to allow the escape of some fresh-formed matter. The leg and thigh are so much relieved, that the application of poultices has been discontinued, and a roller with simple dressings been substituted. There still, however, remains considerable inflammation, with swelling about the ankle, and dorsum of the foot, surrounding the old cicatrix.

7th. Much better; the countenance has lost the sunken features of typhus; the pulse is stronger, and the tongue nearly clean. The inflammatory action in the leg and foot is also nearly subdued.

14th. The patient is decidedly improving rapidly, both as respects the local and general symptoms.

21st. He improves in his general health daily; but yesterday he had an attack of rigors, and the attention of Mr. Snowdon, the present house-surgeon of the hospital, was attracted to a red and inflamed spot, situated over the anterior spinous process of the ilium; this spot possesses a great degree of tension, and it was thought that an indistinct fluctuation could be perceived in it. Mr. Guthrie directed early incisions to be made in all those spots, by which means he observed the subsequent necessity for larger ones would be prevented.

23rd. The inflammation over the ilium has nearly disappeared without any incision having been made. The incisions in the leg are fast filling up with granulations and convalescence appears to be now about established.

Immense Calculus extracted from the Bladder of a Female.

Case of *Mary Kean*, continued from page 127.

Feb. 18th. Going on favourably. Yesterday a large fragment was found to be making its way through the urethra, which Mr. Snowdon removed with the forceps, when it was found to weigh two ounces. several small fragments have continued to pass at intervals.

21st. She is so far recovered, that she has been again removed to her old bed in Queen Ann Ward. She complains of some pain in the bladder; the urine escapes as fast as it enters by the ureters: the urethra, which was divided as a preliminary step to the operation of breaking and extracting the calculus, does not show any tendency to recover its tone at present. The bladder has been injected with warm water, by direction of Mr. Guthrie, but no additional fragments have come away. This he has ordered to be regularly repeated in order to remove the superabundant mucus, which might otherwise afford a nidus for the lodgement of a phosphatic deposition. She takes an anodyne draught every night.

23rd. No further fragments have been passed from the bladder, and it is believed that the whole of this immense calculus has now been completely evacuated.—the weight of the fragments actually collected, and exclusive of what was necessarily lost at various times, amounting to very little short of seven ounces. A considerable quantity of mucus is secreted by the bladder; the general health and appearance improve: pulse is 100 and feeble; in other respects she is much as at last report. She is ordered to take half a pint of decoction of the pareira blava daily.

—o—

MEDICAL APPOINTMENTS AT NEWCASTLE-UPON-TYNE.

—

To the Editor of the Original London Medical and Surgical Journal.

Newcastle-upon-Tyne, Feb. 19th. 1835.

SIR—It is exceedingly gratifying to find, that the concluding sentence in my last letter is borne out by so splendid an illustration as that afforded by the medical officers of the Birmingham General Hospital and Dispensary. Who that reads Dr. Johnstones address to the Birmingham school, can question the truth of my statement in regard to our medical institutions when compared with those of other provincial towns? and who will attempt to deny that such medical institutions stand out in bold and strong relief from the ground presented by our institutions? Let the governors, let the medical officers, and let the scientific public of Newcastle contemplate the picture, and we shall ere long find either that the medical officers have roused from their lethargy, or that the governors who appointed them to their honourable and responsible situations, will be convinced, that the establishments which they direct with their judgment, and support by pecuniary contribution, may be materially extended in utility. A nobler instance of professional liberality, or of anxiety to advance medical

science, never characterised any set of men, than that which the history of the Birmingham school of medicine (as given by Dr. Johnstone) presents. It would be well for society and still better for the medical portion of it, if such feelings were more generally entertained, as those must have been, which could lead men to merge all private and personal considerations for the advancement of a common cause, like that of the diffusion of medical science and the public welfare.

I now come to the consideration of a question already mooted by me, viz. the "expediency of appointments for life." In my first letter, I stated my conviction, that the operation of this system was decidedly prejudicial both to the advancement of medical knowledge, and to the institutions in which it existed. That this opinion may be questioned by some, I have no doubt; in this respect, however, it only resembles everything which does not admit of actual demonstration. I hope in the following observations to succeed in shewing that my opinion is not a mere matter of speculation, and I also wish to be understood as (for a time at least) quitting Newcastle, and treating the question on perfectly general grounds. What, then, it may be asked, are the real or supposed disadvantages of life appointments to public medical institutions? 1st. Where this system prevails, it renders the establishments subservient to the interests of individuals, rather than to the promotion of the welfare of those for whose relief from suffering they were originally formed. 2dly. It gives undue advantages of acquiring and perfecting professional knowledge, to a few, at the expense of utterly excluding others of equal merit, from a participation in these advantages—and in this way prevents, instead of securing, a constant supply of experienced and practical men to society. 3dly. By placing those appointed beyond all public competition, it effectually exterminates that spirit of emulation, which is not only essential to a zealous discharge of duty, but when absent, opposes one of the most insuperable obstacles to the advancement of medical science. It is calculated to promote indolence instead of activity, in those who have probably attained the height of their ambition—who feel themselves secure against all encroachment—and it too often damps the ardour of those who see only a remote chance of succeeding to similar honours. 4thly. As men often grow old in mind, even prior to the time when bodily infirmities render them aware of it, it is plain that the continuance of such persons in office, is a serious evil to the hospitals and their inmates. 5thly. It fosters feelings of envy and jealousy, instead of honourable rivalry amongst the members of the profession, and in many instances render those who know not how to enjoy their good

fortune, odious and contemptible in the estimation of persons who ought rather to look up to them as placed in a situation to which they are entitled by their talents, and to which they themselves, in time, might also aspire. If I were disposed to enter into speculations upon this subject, I might add materially to the above list of evils, but as I have myself seen those enumerated in full operation, I shall not weaken the arguments against life appointments by calling to my aid other imaginary or unproved evils. It now becomes a question, how these disadvantages may be avoided? In answer to this, I would recommend the appointments of Physicians and Surgeons to hospitals and dispensaries to be for a term of years (three or five), and by allowing of their re-election after a certain time had elapsed, it would not only extend the utility of the institutions, but would also prevent the semblance of injustice to those who had served them. It is to be remembered that most hospital appointments are altogether honorary, and consequently no real injury is sustained by the parties who for a time only become disqualified. If however this plan be deemed objectionable, there is another to which I certainly give the preference, especially when an institution has a plurality of officers. Let us for example suppose the hospital to have four physicians and four surgeons, and in addition to these two assistant physicians and two assistant surgeons, that the term of these appointments is three years; I would propose that at the expiration of that time, the two seniors in each department should be elevated to the rank of consulting officers, the two juniors succeed them as senior officers, and that the place of the latter should be filled by the assistant officers, two new assistants being at the same time elected. At the end of the next three years the two consulting officers go out, and the vacancies are to be filled up in the manner above described. The advantage of this system is, that it ensures the qualifications of every officer for the duties of his office. It extends the advantage of the hospital to a large proportion of the profession, and in this way also confers upon society a numerous class of well educated and experienced practitioners. If such a system were adopted, it is obvious that the shortest term that a man would be in office would be six years, a period which would not only afford him the opportunity of extensive practice, but also enable him to display his talents, and establish a professional reputation, which is the first object with every member of the profession. If on the contrary his abilities be below par, the institution would labour under a temporary instead of a permanent evil, which consideration alone should be to the governors of public medical charities a sufficient ground for adopting either this

or some similar arrangement. I shall now take my leave of the infirmary—and subscribe myself

Your obedient servant

GEORGE FIFE, M. D.

P. S. In my next I shall proceed to make some observations on the dispensary.

MEETING AT THE COLLEGE OF PHYSICIANS.

THE second meeting for the season took place at the College of Physicians on the 23rd inst., when a large assemblage was present. A paper was read from Dr. Hope, on apoplexy caused by diseases of the heart, and another from Dr. Veitch, on the prevalence of cholera in marshy districts.

Carbonate of Soda Lozenges.

M. Beral gives the following as the formula of these lozenges, which have also the aliases of "Digestive Pastilles of d'Arcet," and "Pastilles of Vichy":—

Powdered sugar..... 34 ounces,
Powdered bi-carbonate of soda 2 ounces,
Mucilage of gum-arabic..... 36 drachms.

Mix the bicarbonate and sugar well; add the mucilage in the quantity prescribed, or as may be needed, and make a paste of it: roll it out and divide it into lozenges of 18 grains each. Each lozenge contains a grain of bicarbonate of soda.

The lozenges may be made with rose-scented mucilage, with orange, peppermint, chocolate, or tolu or iris-root.

The rose and orange mucilages alluded to, are made by dissolving one part of the gum in three of rose or orange flower water.

By mixing eight drachms of tincture of tolu with eight ounces of sugar, and using a proportion of this in the manufacture of the soda lozenges, the flavour and properties of tolu accompany the latter. With iris-root a very pleasing scent is given to the breath.—*Journal de Pharmacie*, Feb. 1835.

CORRESPONDENTS.

Communications have been received from Dr. Fyfe, of Newcastle-upon-Tyne—Dr. Jacob, of Maryborough—Mr. Williams, of Gosport—Democritus—Dr. Corrigan, of Dublin—A Dublin Friend—A Lover of Fair Play—Guyensis—and a Member of the Medico-Botanical Society; all of which will receive our earliest attention.

J. O. B.—Many thanks for the recommendation.

An Irish Subscriber.—This Journal is forwarded with the *Lancet* and *Medical Gazette*, and reaches Dublin with them every Monday morning. The remedy for not receiving it is to change from the person who does not supply it regularly; this will soon bring him to his senses.

Dr. Corrigan's Clinical Lectures, delivered at the Jervis-street Hospital, are now commenced, and will be regularly continued. We also expect his lectures on Auscultation and Diseases of the Chest. He is the best stethoscopist in Dublin.

An Inquirer.—We cannot inform our Correspondent when the prizes will be awarded by the Medical Reform Society—Dr. Epps's address is 89, Great Russell-street, Bloomsbury-square.

Mr. Cooke, of Northampton.—The communication has been received.

LECTURES

ON

MEDICAL JURISPRUDENCE,

DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,*At the University of London; Session 1834-35.*

LECTURE XX.

Mental Alienation.

GENTLEMEN—The subject to which I have now to direct your attention, Mental Alienation, is the most interesting in the range of our inquiries, involving questions respecting the immortal part of our being, which have hitherto been, and perhaps ever shall be, covered by a veil of mystery, impenetrable in this temporary stage of our existence. It is impossible, in such an inquiry, not to deviate into the labyrinths of metaphysics; but, if we are forced to step into these, let us take common sense with us, like the thread of Ariadne, to guide us back from their devious mazes.

It has been well remarked, "that the attempt to define the nature of mind or soul is as vain and presumptuous an undertaking as it is to try to find out, by thought alone, the nature of the Almighty." Yet (such is the vanity of man), this arduous task has not only been attempted, but some speculative philosophers have decided that *mind* and *brain* are equally substantial and the same. "Continuing to reflect," says Dr. Priestley, in his celebrated work on Matter and Spirit. "upon the subject, I became satisfied that if we suffer ourselves to be guided in our inquiries by the universally acknowledged rules of philosophizing, we shall find ourselves unauthorized to admit anything in man besides that body which is the object of our senses." Others have asserted, that, although both are matter, yet that they are not the same kind of matter. Let us examine briefly the grounds upon which these hypotheses have been erected.

The first of the arguments which have been advanced to prove the materiality of mind is that we have never found the phenomena of perception unconnected with organized masses of matter; they may, there-

fore, be regarded as qualities of such substances; for it is no objection to affirm, what may be said of all the other qualities with which we know matter to be endowed, that they have no resemblance nor affinity to the more acknowledged primary qualities of matter. It is contended, therefore, that mind is always found in conjunction with a certain mass of solid and extended matter; that it inhabits the same portion of space, and presents itself invariably along with those other qualities, the assemblage of which makes up our idea of organized matter. "In fact," says Dr. Priestley, "there is just the same reason to conclude that the powers of sensation and thought are the necessary result of a particular organization, as that sound is the necessary result of particular concussion of the air; for in both cases the one constantly accompanies the other; and there is not in nature a stronger argument for a necessary connexion, or any cause and any effect." I will not at present stop to refute this hypothesis, which is contradicted by a multiplicity of unquestionable facts, which Dr. Priestley could not be ignorant of, but over which he has certainly thrown the veil of neglect, in support of the pride of opinion. We are informed by Dr. Hartley, that *perception* is merely a peculiar species of motion, because it is produced by certain mechanical impulses on the extremities of nerves, which transmit it to the brain, and that association is strictly within the analogy of material movement, and something like the vibration of musical cords in juxtaposition. Let us examine this assertion.

By what means do we perceive the qualities of matter? One reply only can be offered—by perception. Does it not, therefore, involve an absurdity to affirm, that that faculty which informs us of the qualities of matter, is itself a quality of matter? If this were true, perception would also be perceived, which is not the case: it is not a quality, but the knowledge of qualities, and certainly distinct from that which is perceived by it. Thence it must be admitted that it is an unwarrantable abuse of language to call *perception* a quality, which is not an object of sense, as all qualities are; which is never conceived to occupy space,

nor to characterise it, nor is endowed with perceptible properties; which cannot be supposed to be an inseparable attribute of matter, and is found in connexion with organized matter, only whilst that matter exists in a certain state, or is alive. If there were no other grounds for rejecting the materialism of mind, this surely is sufficient, that it confounds the act of perception with the qualities perceived, and classes among the objects of perception the faculty by which a knowledge of these objects can only be attained, and which must be exercised before we can possess any conception, "either of matter or its qualities."

What does anatomy say on this subject? If we look into the writings of Morgagni, or those of Bonetus, of Haller, and of others less distinguished, but equally correct, we find that the texture of every part of the brain may be morbidly altered from its natural state, and yet all the faculties of the mind remain entire. Abscesses have been formed in the brain; tumours have been found in it, which have slowly enlarged and hardened; its arteries have been ossified; indeed, every portion of it, in different instances, have exhibited morbid alterations of structure, and yet the mind has remained entire. Even when it has suffered in the exercise of its faculties, either from general or local inflammation, as soon as this diseased action has subsided, although it may leave behind it some organic mischief, this may continue for many years without affecting permanently the faculties of the mind. Equally strong proofs might also be quoted, that the faculties of mind do not decay, as has been *boldly* asserted, as the body grows old and infirm; for when the mental faculties have been properly cultivated and exercised, the mind shines forth in all its pristine vigour, at the very moment when the body is sinking into the grave. What is the inference to be drawn from this? Can it be other than that mind is perfectly distinct from the *material substance* which enters into our corporeal frame? Give an example, it may be said. The only difficulty is in the selection—"Quid jurisconsulti?" says Cicero, in his defence of old age, and in proof of the fact, that if study be not abandoned, the mind continues vigorous to the last; "Quid jurisconsulti? quid pontifices? quid philosophi senes? quam multa meminerint! Manent ingenia senibus, modo permanent studium, et industria; nec ea solum in claris et honoratis viris, sed in vita etiam privata et quieta." Did not Sophocles write tragedies of an immortal stamp in extreme old age? Did the mind of Voltaire decay with the wasting of his frame? Did the brilliant intellect of Burke melt down with his bodily structure? On the contrary, do we not find, in the last publication of Burke, all the vigour of thought, the vividness of imagination, and the splendour of language

which characterise the compositions of the meridian of his life? What can be found of decay in the productions of the last days of Bishop Burnet, stretched on the rack by the tortures of stone, and a complication of maladies? or in those of Samuel Johnson, whose whole life was one paroxysm of disease? Did the mind of Newton share the weakness of his body, when, in his eightieth year, he resolved the celebrated problem of trajectories of Leibnitz, as an evening's amusement? and, finally, in our own time, what dependence of mind on body was seen in the closing hours of the life of Wollaston, who exercised his mental faculties when his body had almost become extinct. "Nullum sæva caput Proserpina fugit"—but mind remains untouched.

It has, nevertheless, been contended, as I have said, that, although it were admitted that brain and mind are distinct, still this is no proof that mind is not material. I admit the force of this reasoning. Many of the external phenomena of the mind may be accounted for on the known influence of mechanical and chemical powers operating on irritability and sensibility, or, in other words, on the nervous energy. But, although the transmission of such impressions to the brain can be readily accounted for, yet the thought which is produced, the idea which arises, cannot be accounted for: the belief that it is the result of an immaterial agent, forces itself upon the mind: it is a matter of faith, not of reason. We know nothing more of it than what Revelation has taught us, and beyond this it is probable we shall never advance. The connection, however, between the material agent by which a knowledge of external objects is communicated to the mind, and the mind itself, is so close, that it is evident the one cannot be affected without the other suffering: a diseased state, therefore, of the brain may produce insanity, but it is not a necessary consequence; and individuals have died in a state of insanity, the examination of whose brains has not displayed any obvious change to which the disease could be attributed.

I have thought it necessary, Gentlemen, to make these brief remarks on the connection between mind and body, that, being aware of my conviction of the immateriality of mind, I may not be misunderstood in some of the details which I must necessarily bring before you in pursuing this part of our inquiries. But it may be justly demanded—To what useful or practical conclusions does it lead us? In my opinion, it is one of the utmost importance. If we regard mind, or all mental phenomena as affections of the soul, and the functions of the brain and nerves as merely instrumental processes, we shall be led to admit that two species of insanity may exist, or at least differ in their origin; one a malady purely of the mind, the other a malady originating

in the material organs, the brain and nervous system, either primarily affected, or sympathizing with some lesion or functional disorder in one or more of the vital organs. In regarding the first form of insanity, in medico-legal inquiries, our investigation must be strictly in reference to mental causes, such as various passions of the mind, loss of friends, shame, sudden terror, remorse, religious enthusiasm, and such like; in investigating the second, the state of the corporeal health must be strictly inquired into, as the probability of recovery may depend solely upon correcting the functional disorders affecting the nervous system; for, if such a discrimination be essential in a curative point of view, it is also of the highest importance in determining legal questions connected with insanity.

Insanity, in all its forms, frequently becomes an object of legal investigation, and necessarily involving medical evidence. No man who is of insane mind is an accountable being. "It is the reason of man," to use the language of Lord Erskine, "which makes him accountable for his actions; and the deprivation of reason acquits him of crime;"—"it annuls a man's dominion over property, it dissolves his contracts and other acts, which otherwise would be binding, and it takes away his responsibility for crimes." "Non compos mentis," says Lord Coke, "is of three kinds: 1st. *idiotia*, which from his nativity, by a perpetual infirmity, is non compos mentis: 2ndly. he that by sickness, grief, or other accident, wholly loses his memory and understanding: 3rdly. a lunatic that sometimes has understanding, and sometimes not, *aliquando gaudet lucidis intervallis*; and therefore he is called non compos as long as he hath not understanding." It is further justly said, that there is a partial insanity, and a total insanity: the former does not excuse a person for committing crimes of a capital nature; the latter places him without all responsibility. But this latter condition must be accurately defined, and I will employ here again the words of that distinguished counsel, whose remark on the accountable nature of man I have already quoted. "He alone," says Lord Erskine, "can be so emancipated, whose disease, call it what you will, consists, not merely in seeing with a prejudiced eye, or with odd and absurd peculiarities, differing, in many respects, from the contemplations of sober sense, upon the actual existence of things, but he only whose reasoning and corresponding conduct, though governed by the ordinary dictates of reason, proceed upon something which has no foundation or existence." Now, such being the case, who is to decide, who to determine this state, except the physician? For example, the property of all lunatics—or, in the language of the law, those non compos mentis—is placed in the guardianship of the crown; or rather, the Lord Chancellor is the trustee of

the crown for the preservation of the property of the lunatic, until he be restored to reason. The importance, therefore, of obtaining a sound decision is obvious; and the physician is usually called upon for this purpose, both as refers to the deprivation and the recovery of sanity. Again, by an act of the 15th George 2nd., cap. 30, the marriages of all persons are annulled, who, after being found lunatics on inquisition by commission under the great seal, or after being committed to the care of trustees by act of parliament, shall marry without the Chancellor's declaring them of sane mind*."

If we inquire what the criminal statutes say on this head, we find that in acts of felony, "the wrongs of a madman shall not be imputed to him, for that in those cases, *actus non facit reum nisi mens sit rea*, and he is *amens*, id est, *sine mente*, without his mind or discretion; and a madman is only punished by his madness†." Who, then, I again inquire, is to determine the existence of this state? Certainly, it can be determined only by the physician. A person who is insane may discover to ordinary observers no symptom whatever of his disorder; his whole conduct may be marked by ability and composure; yet he may be under a delusion, which impels him to commit certain acts for which, undoubtedly, he cannot be regarded as legally responsible. To illustrate this remark by an example, let us take an incident in the life of Hatfield, who was tried for shooting at George 3rd., in Drury Lane Theatre, in 1800. That unfortunate man had a child eight months old, of which he was most passionately fond. On the day on which he attempted the life of the king, he went to the bed-side of the mother, who had the infant in her arms, and whilst the tears of affection for his offspring ran down his face, he seized and endeavoured to dash out its brains against the wall, but, happily, the child was rescued. This man was perfectly conscious that he was the husband of the woman, and the father of the child; he knew that it was criminal to perform the act which he contemplated; but he acted "under the overruling dominion of a morbid imagination, and conceived that he was acting against the dictates of nature, in obedience to the superior command of Heaven, which had told him, that the moment he was dead, and the infant with him, all nature was to be changed, and all mankind were to be redeemed by his dissolution." When such thoughts were not present in the mind of this unfortunate man, all his acts were those of a rational being. Now, who can sift and determine this state of mind, especially when it is connected with, as in Hatfield's case, and dependent upon, injury to the

* Coke on Lyttleton—Hargrave's notes, 80, a. n. 1.

† Ibid, 247, b. n. 2.

brain, from wounds inflicted upon the head: or, when it is the consequence of hereditary taint, which is too often the case, if it is not the physician? Now, what is the inference to be deducted from these facts? It is this, that as the medical practitioner is called upon to determine the existence of insanity, and he must state his reasons for any opinion which he may advance upon the case, the necessity for a familiar acquaintance with the pathology of the disease is very obvious. He must have a correct notion of sound mind, and know the limits of insanity so intimately, as not to confound with it diseases which resemble it in some points, but under which a man is fully capable of managing his affairs, is a responsible agent, and displays that regularity in conduct which entitles him to maintain, unmolested, his place in society. It may be supposed that these points might be more readily determined by individuals not of the medical profession, who have opportunities of knowing the habits, and observing the ordinary conduct of the supposed madman, than a physician can enjoy. But this is a loose mode of reasoning: the opinions of ordinary observers, and those not of the medical profession, are seldom correct. From want of opportunities of seeing the disease in its various forms, the opinions of the majority of mankind regarding insanity are so vague and extravagant as to mislead them, unless the disease display itself in *violence* and *turbulence* of conduct: and frequently eccentricities are mistaken for insanity, which would lead to the most distressing consequences, if measures to confine individuals were permitted to be taken upon such evidence. One of the most striking features of insanity to the experienced is wholly overlooked by those unaccustomed to contemplate the disease: I refer to the cautious manner in which real madmen often evade the point upon which their madness hinges; and, unless the individual who is in conversation with a madman leads him to the point (a circumstance which is seldom attempted), except by the physician, his insanity is not apparent, and he is pronounced sane. On the contrary, this "*stifling the disorder*," being known to the medical examiner, the conversation is frequently changed; and the decision should not be pronounced until many opportunities are afforded to ascertain its correctness. Lord Erskine, in defending Hatfield, mentioned, in his celebrated speech on that occasion, a very striking instance of the cunning with which madmen sometimes stifle their disorder. Lord Erskine had wasted a whole day in a vain endeavour to demonstrate to the judge and jury the insanity of an unfortunate gentleman, who had brought an action against his brother and the keeper of a madhouse for confining him in a madhouse, when he asserted his perfect sanity. He replied so well to Lord Erskine's queries,

that the judge, the jury, and the audience, believed that he was sane, and the victim of wanton oppression. At length Dr. Sims came into court, and suggested to Lord Erskine to inquire whether he did not believe himself to be *Jesus Christ*. Lord Erskine took the hint, and pretended to lament his ignorance, and the indecency of his examination: the poor gentleman expressed his forgiveness; and, with the utmost gravity, in the face of the whole court, emphatically exclaimed, *I am the Christ*. It is unnecessary to say how the cause ended. Another case, mentioned by the same eloquent lawyer in the same trial, also deserves to be mentioned. (Howel's State Trials, vol. 27, p. 1318). In examining, therefore, a suspected madman, we ought to be certain that we fully comprehend the character of *sound mind*. And here, Gentlemen, I cannot avoid lamenting how little attention is bestowed by those who are entering our profession, on the study of what is termed the *philosophy*, but which I would designate the *physiology* and *pathology* of the human mind. It is the deficiency of this species of knowledge which permits the shadows of insanity imperceptibly to lengthen, till the whole darkness of its night settles upon the understanding. On the contrary, it is by an acquaintance with the philosophy of mind that the practical physician is enabled to measure the power which the mind of his patient possesses over the train of his thoughts, and by detecting any aberration from its usual or healthful state, to take the earliest means to counteract a tendency to insanity; or, if the disease already exist, to distinguish between those intermissions which constitute lucid intervals, and the termination of the malady.

But, to return to the subject immediately before us, it may be reasonably demanded, What are the indications of a sound mind? The best reply, perhaps, is, that they are the reverse of those of insanity: it is too general and loose a definition to say, that a man whose "conduct is regular and whose observations are pertinent," is in his senses; such states, as you have already heard, are often observed in the lucid intervals of insanity, whilst yet the disease is progressing, and whilst even it actually exists. This remark is beautifully illustrated in a case mentioned by Cervantes, in his preface to Don Quixote.

(Here the Professor related the story of the madman who thought that he was Jupiter, and yet was sane on every other point).

Without, therefore, endeavouring to give you a definition or description of *sanity*, I shall leave you to form your idea of it from a knowledge of the symptoms of the opposite state; but, before detailing these, I will point out to you the characteristics of those maladies which approach so closely upon insanity, that they may be mistaken for it.

In all of these, a certain degree of mental alienation may exist; yet not sufficient to deprive the patient of his liberty, or of the management, to a limited extent, of his own affairs. Among these I have not placed the delirium of ordinary fever and phrenitis; for although the actions of those labouring under the delirium of these diseases are to be regarded, as far as requires coercive restraint, in the same manner as those of the furious maniac, yet there is little chance of the two states being confounded.

The first of the diseased states likely to be mistaken for real insanity is hypochondriasis. This is truly a bodily disease in which the nervous system is greatly deranged, and that chiefly owing to a dyspeptic state of habit, often connected with intense application to some particular course of study of a sedentary nature; and, consequently, it is a frequent disease of literary and scientific men. The distinction which Dr. Cullen draws between it and insanity is so admirable, and so correct, that it would be idle in me to attempt to improve upon it; and, therefore, I will quote it to you in his own words. Before doing so, however, I will remark that one thing may direct us in forming a diagnosis, which requires no discrimination to discover—I mean the age of the patient—hypochondriasm seldom making its attack until after the middle period or prime of life, whereas, melancholic mania generally appears before that period. “Hypochondriasis,” says Cullen, “I would consider as being always attended with dyspeptic symptoms; and though there may be, at the same time, an anxious melancholic fear arising from these symptoms, yet, while this fear is only a mistaken judgment with respect to the state of the person’s own health, and to the danger to be thence apprehended, I would still consider the disease as hypochondriasis, and as distinct from the proper melancholia. But when an anxious fear and despondency arise from a mistaken judgment with respect to other circumstances than those of health, and more especially when the person is at the same time without any dyspeptic symptoms, every one will readily allow this to be a disease widely different from both dyspepsia and hypochondriasis.” The truth of this distinction must be admitted by every one who has ever seen the two diseases. The flatulences, the acid eructations, the discharge of pale urine, vertigo, palpitations, and the inability to engage in any thing requiring vigour or courage, distinguish hypochondriasis as far as regards corporeal symptoms. As far as regards the mental feelings, one of the most striking features which distinguish hypochondriasis from insanity is, that the erroneous ideas which the hypochondriac conceives generally concerns his health, or the state of his bodily frame; whereas in melancholia, they consist of various phenomena of grief, despondency, and despair. The dread of death often over-

shadows the mind of the hypochondriac; and it is this morbid apprehension which embitters his life; yet, “he prefers the rack upon which he is stretched, to the repose of the grave.” When he becomes indifferent to his fate, then the applications of art powerfully aid the operations of Nature, and he is restored to that health which he in vain sighed for, when the inordinate fear of death constantly haunts his imagination. When remorse becomes a feature of this disease, and there is a disposition in the patient to calumniate himself for some fancied error, to consider as misconduct, that which is merely mischance; in this state of the mind, hypochondriasm amalgamates, as it were, with insanity, and frequently terminates in it. This is often merely the consequence of a dyspeptic state of the digestive organs, brought on by too close application to one course of study; the imbecility of mind which it produces becomes perceptible to the hypochondriac; he supposes that it has arisen from lost opportunities of improvement: he shuns society, if a literary man; he pores over his books, yet finds he gains nothing:—fancies that he knows nothing, and falls into despair—the depressed state of the mind deranges the entire functions of the nervous system, and insanity is the result.

Another distinguishing feature of hypochondriasis is pointed out by Foderè, connected with the selfish feelings which predominate. The hypochondriac is credulous, variable, and timid; the melancholic madman is reserved and prudent, but neither devoid of courage, nor incapable of generous and noble sentiments. The hypochondriac, from being able to reason more accurately on the nature of good and evil, may talk of suicide; but, unless the disease changes its character and slides into insanity, he never accomplishes the act. In another point of view also, the hypochondriac differs widely from the madman; his feelings and affections are in a natural state; those of the madman in every form of insanity are in an unnatural and perverted state, and form the most characteristic features of the disease.

Hypochondriasm, however, is often attended by illusions closely bordering on hallucination; and when these occur it is difficult to distinguish this disease from insanity. I do not here refer to the whims and caprices of the hypochondriac, so well and ludicrously described by Pope:—

“Here living tea-pots stand, one arm held out,
One bent; the handle thfs, and that the spout;
A pipkin there, like Homer’s tripod walks,
Here sighs a jar, and there a goose-pye talks;
Men prove with child, as powerful fancy works,
And maids, turn’d bottles, call aloud for corks.”

Such fancies as these do not belong to

hallucination, which consists in an idea embodied by the imagination, and so associated with the ordinary affairs of life as to be constantly reproduced by the memory. A beautiful illustration of this symptom of hypochondriasm is found in the interesting story of the celebrated Nicolai of Berlin, drawn up by himself; it is too long to read to you:—you will find it either in Ferrier on Apparitions, or in Haslam's pamphlet on Medical Jurisprudence, as it relates to insanity.

Nicolai, who was a man of letters, and possessed of great talents, was all along conscious that the spectral forms which haunted him were delusions, otherwise the disease certainly would have been correctly regarded as insanity. I cannot refrain from relating to you a very curious instance of hallucination related by Sir Walter Scott in his Letters on Demonology. (The professor here related the story of the phantom). Notwithstanding the continued illusion in this case, there was no insanity; the hypochondriac had no belief in the reality of the spectral form which haunted him; if such had been the case, his disorder would no longer have been hypochondriasis but true insanity. Thus, in the case of the Baker of Ferrari, recorded by Donatus, who believed that he was made of butter, and on that account would not approach the oven lest he should melt, the disease was no longer hypochondriasm but true insanity. These illusions depend both on corporeal and mental causes; when they proceed from the former, the health of the brain remains entire: the patient is a reasonable man in all other respects; when from the latter, the brain is always disordered, either by the unequal exercise of it, or hereditary predisposition. Thence, the difficulty in distinguishing between hypochondriasm and insanity, when hallucinations are present (for they occur in both), is certainly great; but in one thing they differ: the hypochondriac does not believe in their reality;—they are in general only transient, whereas in insanity, they are not only permanent and fixed, but there is, also, a rooted conviction of their reality—an implicit belief in the delusion. But notwithstanding this test, many cases have been correctly recorded as instances of hypochondriasm which should apparently have stood as cases of insanity; as a proof of which I shall mention a case related by Marcus Donatus, of one Vicentinus, who imagined that he was of such an enormous size that he could not go through the door of his apartment. He was led forcibly through it, and believed that, in the passage, the flesh was torn from his bones, and that his limbs were broken off. In a few days he died of this impression, accusing those who had conducted him of being his murderers. Now, in this instance, the erroneous idea of his size was truly hypochondriacal; and, yet it is difficult to con-

ceive, that the conviction of the effects of forcing him through the passage, could have been so deeply rooted in a sane mind. This, however, is a rare case, and attention to the circumstances which I have pointed out, generally will enable the practitioner to discriminate between *hypochondriasm* and *insanity*.

Epilepsy is often connected with insanity, and it may be mistaken for it. It is a disease which, when connate, terminates in dementia; and even when symptomatic, weakens the memory and impairs judgment; but, in many instances, it is totally free from every symptom of insanity, and, consequently, ought to be carefully distinguished from it. It is, however, in long continued epilepsy only, when, from the repetition of the attacks, the powers of the brain, the intellect, and the memory, are so weakened, that the physiognomy of the countenance seems to anticipate the termination in either mania or idiotcy, that it is likely to be mistaken for dementia.

Intoxication produces effects closely resembling those of insanity. After a certain quantity of wine or any strong liquor has been swallowed, a state of real delirium ensues:—"the person talks idly and unreasonably; vociferates loudly; speaks in broken and incoherent language; emits screams; swears alternately; and has no command over his actions. In this case, there is an evident determination to the brain; and the symptoms closely resemble those of a paroxysm of phrenitic mania. But, although it must be admitted that those who are labouring under delirium, from whatever cause, differ, at the time, from those of sound mind, inasmuch as they firmly believe the diseased perceptions and notions which are passing through their mind, and adopt them as motives of actions and expressions at variance with those of reasonable men, yet this is not sufficient to authorise their confinement in a lunatic asylum. It is true that, when intoxication becomes habitual, it is not an unfrequent cause of insanity, and even of furious mania: but in the early stages of these cases, if the exciting cause be withheld and the convalescence is so far advanced, that the patient is capable of receiving sustenance from the ordinary articles of diet, the natural vigour both of body and mind return: and when this occurs it then becomes a criminal act to detain the objects of them longer in confinement; although the almost invariable consequence of such an enlargement is a return to those habits which produced the temporary aberration of judgment. After a few accessions, if the disease do not terminate in epilepsy or death, it produces a state of confirmed fatuity. In granting certificates for the confinement of such individuals, we must be careful that the habit is proceeding so far as to threaten to render the alienation permanent: the conduct

the individual, during the intervals of temperance, must be particularly inquired into, as it is only upon such data that we can judge of the state of mind, and safely and justly authorize the restraint of confinement. In law this species of insanity is termed *dementia affectata*; and there is a particular reference to the causes of it, in the liability of the person for the commission of any crime during its continuance. (See Russell, vol. 1. pp. 7, 8).

The peculiar aspect of the individual, an expression of countenance which cannot readily be described, but which is acknowledged, at first sight, points out the cause of this state of temporary insanity; and, therefore, until it is found that measures taken to restrain the repetition of this fascinating vice are wholly ineffectual, we cannot consider ourselves authorized to place the wretched victims within a lunatic asylum. If we are called to see the patient during the paroxysm, it is impossible to judge between it and that of furious mania, as it is never inferior to this in violence; but it is generally of much shorter duration. If, independent of the history of the case, we observe the diagnostic aspect which I have mentioned, caution at least is requisite in granting a certificate for the confinement of the person. In Scotland, a man who has become an habitual drunkard, and has lost all control over his inclination, has the power of placing himself under trustees, who have the complete control over all his transactions, and can alone give them validity. This is termed *inhibiting one's self*. In some of its effects, habitual intoxication causes a state of the brain closely allied in every respect to insanity; I refer to that affection which is termed *delirium tremens*. The hallucinations attending this disease are exactly those of insanity, and are as sincerely believed: the patient sometimes believes that he is beset by assassins; and instances have occurred in which the efforts to ward off their supposed violence have overpowered the strength of the unfortunate individual, and suddenly terminated in death. When the delirium is completely established, the same watchfulness occurs as in insanity, and the countenance assumes an aspect of extreme anxiety. Indeed, were it not for the tremors of the hands and tongue, the working of the tendons of the wrists, the absence of malignity in his vehemence, and the knowledge of the previous habits of the patient, the diagnosis would be most difficult between a paroxysm of delirium tremens, and mania. I have frequently authorized the temporary confinement of the insane from drunkenness; and as frequently have witnessed its beneficial influence: but in no instance do I recollect of its having produced a permanent cure. When the habit becomes confirmed, there is rather a decline of intellect than positive derangement; no aid, in this case,

can be derived from medicine; the case may be considered hopeless; the patient is exactly in the state of any other insane person, as far as regards the management of his affairs, or his power of making any legal testamentary document.

Hysteria displays itself most commonly in mobile and irritable temperaments; it occurs most frequently at that period of life when irritability is at the height; and not unfrequently is the result of mental emotions. It is unnecessary to describe the entire hysteric paroxysm; but it resembles insanity in many points. Thus it is accompanied with watchfulness, or disturbed sleep, terrible dreams, perverse conceits and opinions, dejection of mind, discontent, and preposterous judgment. There is often something like *tædium vitæ*: the persons thus affected weep, tremble, despond, and are out of all hope, seek solitude, and preserve a foolish kind of bashfulness. "They indulge," says Sydenham in his masterly description of hypochondriacal hysteria, "terror, anger, jealousy, distrust, and other hateful passions; and abhor joy, and hope, and cheerfulness, which, if they accidentally arise, as they seldom do, quickly fly away, and yet disturb the mind as much as the depressing passions do; so that they observe no mean in any thing, and are constant only to inconstancy. They love the same persons extravagantly at one time, and soon after hate them without a cause; this instant they propose doing one thing, and the next change their mind, and enter upon something contrary to it; so unsettled is their mind that they are never at rest." This painting is true to nature, as the occasional portrait of the hysterical mind. When called to a case of this kind, the medical practitioner ought to enquire minutely into the private history of the individual, and every collateral circumstance connected with her family; whether this be her first, or second, or third attack; whether insanity had prevailed in the family; whether any injury of the head had happened; whether there is any suppression of the catamenia or other customary evacuations; and the state of the mind as to grief, anxiety, or disappointment.

I have witnessed cases of high delirium in hysteria, which so closely resembled insanity; that, unless I had been witness to the whole progress of the attacks, I must have set this down as paroxysms of furious mania. The females were women of good families and education, and correct moral feelings; yet the delicacy of their sex was completely set aside; and the language employed, during their ravings, such as would have disgraced the most abandoned and lost of their sex. In such cases, inflammation of the substance of the brain is present; and the derangement of the intellectual functions can only be attributed to it: but, if we venture to theorize on the disease, it is

difficult to say whether the morbid appearances thus observed in the brain, on post mortem examinations, be the cause or the consequence of the attending insanity, which certainly in these cases accompanies the hysterical paroxysm. I will not, in this place, venture to give an opinion upon this subject; it is sufficient for me to point out the necessity of distinguishing between these temporary aberrations of reason, which subside whenever the disease to which they are adjuncts yield to remedies, and permanent insanity, which they simulate. In a medico-legal point of view, this is a matter of the utmost importance; and nothing would lower medical character so greatly as to send into confinement, as a furious maniac, an individual labouring under a paroxysm of *hysteria*.

If *hypochondriasis* may be confounded with, and be mistaken for insanity, that disease which has been termed *nostalgia* is much more likely to be so; and where this occurs, and confinement in a lunatic asylum takes place, death is the inevitable result. In no disease is the influence of mind on body so strikingly displayed as in *nostalgia*; without implying a metaphor, "the worm of mental malady," as Dr. John Reid beautifully expresses himself, "may be gnawing inwardly and undetected, at the root of the constitution," whilst the physician is solely occupied with some obvious and superficial symptom. In this disease the power of intellect over organized matter is most striking, and fully demonstrated, in the state of the lungs and liver, when the fatal termination of the disease affords an opportunity for the examination of these organs. The small extent of materia medica and pharmacy in affording remedial agents is thus displayed; and a proof, if any were required, is presented of the inseparable connection between moral science and the healing art. This combination is essential for the knowledge of mental alienation; and particularly so, for the discrimination of *nostalgia*, as it is frequently, although not always, in the highest and most cultivated persons that it displays itself; "the mind, in proportion as it is expanded, exposing a larger surface to impression."

I once saw the disease in a Scotch artizan; and Mr. Dunlop, in a note published by Dr. Beck, states that the only cases of the disease which he ever met with, were two:—one in a recruit, a country lad, from the fens of Lincolnshire, "who died," says Mr. Dunlop, "under my charge, on his passage to Canada, in the year 1813; and the other, a London pickpocket, whom I saw this year, 1824, in the hulks of Sheerness."

Nostalgia may be mistaken for melan-

cholia, by the restlessness and want of sleep which accompanies the disease; the strong tendency to self-destruction which attends it, when the desire of revisiting the country which is longed after cannot be accomplished; life becomes then a burthen, and the *tedium vitæ* leads to real insanity, terminating in suicide. From what has been said, the necessity for distinguishing *nostalgia* from insanity, when the distinction may prove serviceable, must be sufficiently obvious.

The last state which may be mistaken for insanity is the *imbecility of old age*. Man in his course of life seems to describe a circle, or to perform his course in an orbit; so that when it is naturally completed, he returns to the point from which he set out. In this state, the mind itself seems incapable of any progression; it lives upon its acquired stock of ideas, and is even so weakened, that the person becomes unfit to manage his affairs; and he must be treated either as a child, or as a lunatic. Although, however, in such cases, the law may rightly appoint trustees to manage the affairs of individuals, yet it is necessary that a proper distinction should be made between such cases and insanity; for while property should be protected, personal feelings must also be respected, and every person shielded from oppression or injustice. There is another state which also verges closely on insanity, that which often accompanies the premature senility of licentious youth. In the life of some men there is no manhood;—the day of their career has no noon; their morning, warmed by the scorching sun of excess, is followed by the exhaustion of evening, and the foundation of intellect is sapped before the superstructure is half completed. Still this is not real insanity; and the law does not permit the confinement of such a person, although his property may be placed in the hands of trustees, in the same manner as that of a lunatic. This protection rests entirely with the medical evidence upon which the decision, in any legal investigation connected with such a state, must rest. When insanity really occurs in old age, or when it accompanies premature age, such as I have described, no treatment, either moral or physical, can remove the disease; "the disorder of the faculties in such a case, is not likely to terminate, except in the quiet of idiocy, vacant superannuation, or in their complete extinction, in the calm of death."

Such are the topics, gentlemen, to which I have thought it necessary to direct your attention, as prefatory to the consideration of insanity in a medico-legal point of view, upon which we are now prepared to enter.

LECTURES ON THE INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF
MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE XIII.

Organic Functions—Vital Action or Life.

INORGANIC matters then, have no reciprocal action with the medium in which they exist; whereas there is no plant nor animal, the crude fluids of which do not maintain a continual interchange of gaseous matters with the atmosphere or water in which it dwells, and such an interchange is essential to the conversion of these crude fluids into the mature fluids, which are to minister to nutrition and secretion in general. This is effected generally by means of some proper organ, or the vesicles within the substance of the leaves of plants, or the lungs and their appendages, or some corresponding organs in animals; but sometimes, on the other hand, it is brought about by the surface in general.

Again, the substance of inorganic matters being exclusively either solid, liquid or æriform, it is evident that there can take place in them nothing analogous to a circulation of fluid through solid parts; and, if this be wanting, there can of course be nothing similar to nutrition and secretion on the one hand, or to absorption on the other. New particles may indeed be accidentally formed and deposited within or upon them, and this even after certain definite laws, as in the formation of stalactites, petrifications, &c., and their old particles may be accidentally broken down and carried away; but the former occurs only when such new particles have been conveyed to them by a fluid, which is afterwards removed, and the latter only when some chemical or mechanical power has been in operation. On the other hand, in every plant and animal as the mature fluids are constantly moving in the interstices of the solid, for the purpose of being formed into various new solids and fluids—the former in proportion as they are absorbed, the latter either that they effect some useful purpose in the system, or be carried out of it as useless or deleterious—so the crude fluids are equally constantly in motion, in some parts indeed as instrumental to secretion, but in most for the purpose of receiving again into themselves such solids and fluids as have already fulfilled their respective offices: and having arrived with them again at their respiratory organ, are there once more converted into the native fluid, to go through the same course as before. It is to these actions that the entire and spiral vessels of plants in general, and the heart, arteries and veins, and lymphiferous and chyloferous vessels, with the parenchyma and erectile parts of animals in general are subservient; but in quite the lowest tribes of organized beings it is not through proper vessels, but through their generally spongy texture, that the fluids are moved, and it is in this that all the offices which they perform are effected.

Further, inorganic matters, as they waste no part of their substance by any processes similar to the foregoing, so they do not renew it by receiving into themselves and assimilating foreign matters. But, while plants in general repair their loss by selecting from the soil by means of their absorbing vessels such matters as, with little or no assimilation, become at once their crude fluid, all animals take occasionally from the external world certain solid and liquid matters which they assimilate by a series of processes, called collectively digestion, each to the nature of its own crude fluids, and thus compensate for what has been consumed. It has been proposed as a general ground of distinction between plants and animals, that the alimentary matter of the former are always inorganic (a); and the vegetable kingdom has been thus represented as a kind of laboratory, in which mineral matters become adapted for the aliment of the herbivorous tribes of animals, as these last are a kind of laboratory, in which vegetable matters are rendered fit for the aliment of such as are carnivorous. If the recent speculations, however, respecting the indefeasible nature and perpetual transmutations of organic molecules be well founded, it follows that these proposed distinctions are quite imaginary, and that not only do plants, as well as animals in general, subsist in fact on organic matters, absorbed from the soil—using the water and salts, precisely as animals do, merely as diluents and condiments—but all animals indiscriminately are capable of subsisting on any kind of organic matters, whether vegetable or animal, always, provided that they afford a sufficient stimulus to the digestive organs (b). It may be made a question, however, whether the above distinction

(a) Brisseau—Mirbel, &c.

(b) It is an axiom as old as Hippocrates, that there are many species of food, but only one aliment; but whether he intended to imply by this that the essence, as it were, of every kind of food was primarily the same,

or that it only became so when acted on by the digestive and nutritive powers, is a question. The supporters of the molecular doctrines, however, choose to take the axiom in the former sense. "La matière," says Buffon, "qui sert à la nutrition et à la reproduction

between plants and animals be not objectionable, not so much because *neither* are capable of subsisting on inorganic matters, as because *both* are competent to do so; and whether that between different kinds of animals be not equally so, not so much because either vegetable or animal food will do equally well for both, as because neither the one nor the other is essentially requisite to either. Numerous instances are on record, and to some of them allusion has been already made, in which not only plants, but animals also, and these as well naturally carnivorous as herbivorous, have lived and increased in size when fed apparently on strictly inorganic matters—even on such as appeared to be quite destitute of certain elements in which their bodies abounded; and, however conducive ready-made organic matters may be to these ends, there seems to be no good reason for doubting that every organized being is quite competent so to separate and recombine, by the consecutive processes of assimilation and nutrition, the elements of many inorganic matters—at any rate where they contain all those which are presumed to be in requisition—as to form the immediate materials of its own tissues. Nay, there is good reason to believe that even organic matters are entirely decomposed and recombined by this double process; so that it is, perhaps, only by affording the precise elements, and in the precise proportions that they are required, that such matters are best adapted to the purpose. The principal organs which minister to the process of assimilation in animals—for plants have no specific apparatus for the purpose (*a*)—are the gullet, stomach, and intestines, with their appendages; but in quite the lowest tribes, the alimentary matters are received and assimilated, as well as, when assimilated, turned to their proper account, by the indiscriminate spongy mass of which they are composed.

Between all the above-mentioned actions of organized beings, which minister exclusively to the preservation of the individual, there is a fixed and determinate relation, nor is it severally and after each other, but as far as possible altogether, and with and through each other that they should be contemplated; the remark already made that “while each organ is itself more or less dependent on the rest, it conduces in a greater or less degree to the perfection of all,” being applicable to the fullest possible extent to all those which are concerned in the functions now under consideration (*b*), and this quite independently of the healthy action of each contributing by sympathy, as it also does, to the healthy action of all the others. Thus, unless the respiratory organs were continually supplied with the crude fluid from those of circulation, absorption, and digestion, they could not act reciprocally with the surrounding medium, and thus prepare the mature fluids; unless the organs of circulation, nutrition, and secretion, were equally constantly supplied with mature fluids from those of respiration, all these processes must stand still; and, if such were the case, neither could absorption go on, and whatever alimentary matters were received could never be assimilated, so that the supply of crude fluids would in consequence be cut off from the organs of respiration.

Such however is the economy of organized beings, that those very actions which are directly subservient to their preservation, besides entailing upon them many changes connected with various ages, and many accidental maladies, indirectly tend to exhaust and destroy them; and it is a law therefore of this economy, that every individual plant and animal, having, in a period more or less definite for each, attained its acme of perfection, begins to decay, and each at length—from the insect which perishes within the hour, to the tree which survives the revolutions of centuries—ceases to exist (*c*). To die then is as

de tous les animaux et de tous les vegetaux est la même”—(Hist. Nat. 1750); thus abolishing, at a word, all the above proposed distinctions.

(*a*) Saussure. (Rech. Chim. sur la Végétation, 1804). Hence we may say with Hippocrates, that the soil is the stomach and intestines of plants.—Ventriculus sicut humus—or with Aristotle and Boerhaave, that the vessels of their roots are analagous to the chyloferous vessels—a part of the circulating system—of animals, which comes to precisely the same thing, both propositions serving equally to withhold from plants any proper digestive apparatus. They *select*, rather than assimilate.

(*b*) It is likewise to this circle of actions alone that the well-known beautiful saying of Hippocrates, with respect to the functions in general—Πάντα ὁμοίως Ἀρχὴ καὶ πᾶντα Τέλει—*is strictly applicable.*

(*c*) The age to which animals in general attain is commonly estimated as between seven and eight times the period which they take to arrive at puberty—consequently man is one of the longest livers, at least of mammals, the whale being among the few which surpass him in this respect, as sometimes attaining to the age, it is said, of 300 or 400 years. Aquatic animals indeed, perhaps in general, live longer than terrestrial, the carp (*Cyprinus*, 35), for example, often attaining, it is said, to the age of 100, and the pike (*Esox*, 34) sometimes to that of between 200 and 300. Among trees the lime is computed to have arrived at the age of 580 years, the cypress of 900, the oak of 1600, the yew of 3000, and the celebrated baobab trees of Africa, of 5150; so that it is not improbable that “some individuals, now existing, may have been silent witnesses of the Noachian deluge.”

characteristic of organized beings as to live; and, paradoxical as it may appear, it is a fact, from a distinct vital process, that death in all cases immediately results (a). Inorganic matters, sustaining no changes of this kind by any inherent actions, and incapable of becoming extinct, are of course unprovided with any inherent means of perpetuating their kinds; and the existence of each is quite independent of the pre-existence of any other. On the other hand, organized beings, certain as they are to become individually annihilated, are provided with the means of forming and separating from themselves, at definite periods, certain organized parts, which, becoming at length new beings of the same species, constitute another and another generation, so that, while individuals perish, the race is perpetual. The principal organs which minister to the process of generation, are, in plants in general, pistils and stamens, and, in animals in general, both viviparous and oviparous, the ovaries and testicles, with their respective appendages; but in quite the lowest tribes of organized beings, which are without distinction of sexes or sexual organs, no equally specific parts are appropriated to this function, their propagation being effected, sometimes by a spontaneous division of themselves into distinct beings, when they are called fissiparous, at others, as in the gemmiparous tribes, by the detachment from some part of their bodies of shoots, which become ultimately possessed each of an independent existence. What is properly called generation then is the formation or secretion by organized beings of other organized beings in the likeness of themselves, whether thousands of millions, as in many fishes, or one only, as in man, be at once so formed; but it is not certain that they have not the power also of forming, in a similar way, many other organized beings, distinct as well from themselves, as from each other. Of this nature are parasites: and when we consider that not only every animal, but almost every organ of every animal has its own proper parasites and no other (b); that other, if not living animals, at least living tissues, such as tubercles, encephaloid tumours, melanoses, and schirri, are certainly the products of a specific secretion, and that it is more than probable that all these were at first a kind of parasite (c), possessing each its own rudiments of organic structure, and only by an ulterior process, establishing an imperfect connection with the contiguous parts (d): that at least one kind of parasites, namely hydatids, are often found in parts which are known to have suffered contusions, and have even been artificially produced by this means (e): and lastly, how totally untenable are the various other hypotheses which have been at different times advanced to explain their production—as that they are received into the body with the aliment, &c. in the form of ova, deposited either by animals the natural habits of which is without (f), or by the proper entozoa of other animals previously passed from their bodies (g), or that the said ova are conveyed directly from parent to offspring, either while in utero along the umbilical cord, or after birth with the milk, having been at all times a proper constituent part of the body of the former (h), or lastly, that such parasitical ova are evolved simultaneously with the proper ovum of the being which is to contain them, the former having from the first existed within the latter (i),—we can hardly refuse to believe that the parasites of animals are as much an immediate product of secretion, as their own proper progeny (k); but that as the

(a) A late Professor of the Institution of Medicine, in the University of Edinburgh, no less estimable in every other capacity, than tiresome as a teacher, was accustomed to incur a great deal of unmerited ridicule by prefacing his Lecture on Dissolution, with the remark that he had now to treat of "the last function—Death." He was perfectly correct in his definition.

(b) Thus man is liable to 12 proper entozoa—1 in the lungs, 6 in the intestinal canal and its appendages, 1 in the urinary organs, 1 in the ovaries, 1 in the integuments, 1 in the eye, the brain and the muscles, and 1 lastly, in any organ except the intestinal canal—all quite distinct from numerous other animals which are reported to have been passed sometimes from the stomach, urinary bladder, uterus, skin, and other organs, and the source of all which was in all probability really received ova. Again, the hog (*Sus*, 44), and the sheep (*Ovis*, 45), in their several organs, are liable each to 9 proper parasites: the ox (*Bos*, 45) to 11, the horse (*Equus*, 46), again, to 9, the hare (*Lepus*, 49)

to 8, and the fox (*Canis*, 50), once more, to 9; birds in general have about 7: among reptiles, the frog (*Rana*, 32) is liable to 8: and among fishes, the perch (*Perca*, 20) to 7, and the salmon (*Salmo*, 29) to 8. Almost every organ also of every invertebrate animal seems to be distinguished in like manner by its own proper parasite.

(c) Justamond, Adams, Carmichael, Barron, Fosbroke, &c.

(d) J. Hunter, Doëllinger, Gruithuisen, Meckel, Beclard, Lobstein, Hastings, &c.

(e) Bremser.

(f) Leeuwenhoek, Linnæus, Andry, Boerhaave, Hoffmann, &c.

(g) Pallas, Reinlein, Brera, Rhind, &c.

(h) Valisnieri, Goëze, Bloch, Werner, &c.

(i) Haller, Bonnet, &c.

(k) Rudolphi, Bremser, &c. It is proper to remark, however, that although it is de novo that entozoa are formed, according to these authors, in the animals which contain them, and therefore as the result of secretion, still it is not, they imagine, that of substances organized from the first in the man

former are laid down in numerous organs, and differ in each like their other secretions, so the latter are formed only in the ovaries or corresponding organs, of which it constitutes in like manner the natural and proper secretion. It is indeed difficult to understand how persons who believe that living animals have the power of constantly renewing by secretion their own natural organized tissues, or even whole organs, as well as of depositing such as are altogether preternatural, which—at first isolated—become united with the parent tissue only subsequently, can be startled at the idea of their secreting their own proper progeny, and still more their own proper parasites; but it is only one of the innumerable evils into which the want of a proper idea of the nature of life has led physiologists, that the doctrines respecting generation, in all its forms, have been more vague and visionary than those respecting almost any other function of the body. They think they can comprehend the expansion of a living principle over a larger or a smaller area; but like Malebranche, they cannot understand the creation by one living being of a new living principle, such as is presumed to be necessary to vivify another. The difficulty however is an imaginary one. There is no creation of life in the case—no “Univocal Generation,” as it was called by Redi, or communication of life from one being to another; but only such a new combination of matter by secretion as necessarily developes one of its conditions, namely, vitality, and this, when acted on by the necessary stimuli, gives rise to those phenomena in which life consists (a). Whatever opinion, however, we adopt with respect to the source of parasitical animals, it must lead equally to the conclusion that the existence of every organized being implies the pre-existence of some other, either of the same or of a different species, and thus to the establishment of a broad line of distinction between them and inorganic matters.

The several functions then thus summarily run over, may be represented as primary and essential, and said to constitute the main revolving wheel, as it were, of the organized machine; and however numerous may be, in the more perfect kinds of this machine, the minor wheels which are called at second hand and incidentally into play, it is upon the movements of this that those of all the rest are dependent. Accordingly in the diagram already published, which is intended to illustrate among other things the mutual relations of the functions of the higher tribes of organized beings, these characteristic actions of all such beings are represented as constituting the lowest wheel, to signify their fundamental nature, and at once their independence of all other actions, and their instrumentality in supporting those additional actions which the higher tribes alone of such beings display. These additional actions are those in which sensation, thought, and voluntary motion consist; but into a consideration of these, as it were, adventitious functions, it is inexpedient to enter at present, since, as before observed, they appear to require some other conditions besides those which alone are essential to the foregoing, and which it is our business now to investigate.

It is, then, in the sum of those actions of organized beings which have been above described as fundamental, whether any others be added to them or not, that LIFE appears to consist. Organism and life are, under ordinary circumstances—in other words, under the application of the requisite stimuli—coincident, the commencement of the former producing generally that of the latter, while the cessation of the former gives rise always to that of the latter also; and if we retrace all that has been said respecting each particular feature in the structure of organized beings—their individuality and definite form and volume, the multiplicity of their distinct organs, the co-existence in them of solid and fluid parts, each in a constant state of mutual conversion, and their specific chemical nature—we shall find that every thing relating to their organism or structure has a direct relation to their life, or the actions which they are to perform. Organism and life, then, in this sense of the latter term, may be described as standing in the relation *indirectly* of cause and effect to each other, the former giving rise essentially to the development of a certain property called irritability or vitality, which, when acted on by certain powers, generally in

ner of newly deposited tissues, but of an unorganized mass which, upon its spontaneous separation, gives rise to new living beings upon the molecular principles lately spoken of. To the objections to these doctrines it is unnecessary to recur at present. Every view of the matter seems to favour the presumption that every new animal as well as every new part of every animal, is laid down first as a kind of organized germ formed by secretion; and that the axiom “*Omnia ab ovo*,” in this extended sense of

the word, is still unimpeached and unimpeachable.

(a) “It is absurd,” says Mr. Bushman, in a very succinct and clear account of the various hypotheses which have been advanced to explain the origin of parasites; “it is absurd to talk of finite beings creating any thing, but it is worse than absurd to talk of their creating that which has no existence.” —(*Account of worms found in the reins of a boy*, 1833).

more or less constant operation, produces those actions in the sum of which life consists. This relation, then, of the two may be represented by the following plan:—

This view of the matter, however, has not always, nor even generally been taken; the structure of organized beings having been admitted indeed to be identical with their organism, but not their actions with life; and while it is allowed that this organism and these actions are commonly coincident, it is denied that they stand either directly or indirectly, in the relation of cause and effect to each other, both being described as dependent on life as a substantial principle. The following plan may represent this relation of organism and life:—

It is hence obvious that the word Life is employed in two very different acceptations, signifying sometimes merely that chain of peculiar actions above described as characteristic of organized beings, the immediate conditions of which are to be sought for, partially at least, in a necessary result of organism; and sometimes a substantial principle—an entity, whether material or immaterial (*a*)—which, entering certain aggregations of matter, regulates as well their organization—whence results their organism—as all the other phenomena which they exhibit (*b*). The questions then arise, 1st, What evidence have we of the existence of any such substantial principle? and 2nd, How far is it adequate, admitting its existence, to explain vital phenomena (*c*)? If we fail in establishing both its existence and its adequacy to produce the effects which have been ascribed to it, we must acquiesce in the proposition first advanced, that Life is a mere abstract term used to denote the characteristic actions of organized beings resulting more or less immediately from their organism.

(*a*) It would not have been considered necessary to remind the student that the existence of an immaterial substance—an *δυσία αἰλος*, as well as a *υλη*—has never been regarded as an impossibility, had not some recent writers seemed to imply the reverse. Dr. Bostock, for example, accuses Mr. Mayo—the correctness of whose general phraseology he is pleased at the same time to compliment—with having controverted his own proposition in the very statement of it, where he says, “Mind and matter are logically distinct substances.” (*El. of Physiology*, 1825, vol. i, p. 301). Whether they be so or not, may be questioned; but it is at least certain that they may be so.

(*b*) In ancient times life, in the former of these senses, was called by the Greeks *Ζωή*, and by the Romans, *vita*; in the latter, by

the Greeks *ψυχή*, and by the Romans *anima*. We have unfortunately no single term by which to designate the supposed substantial principle, if we employ the word life to signify merely the chain of actions, and no one by which to designate the chain of actions, if we apply the word life to the supposed substantial principle. We can do better, however, without a term for the principle than for the actions.

(*c*) It is a rule of the immortal Newton, of which we are aptly reminded by Dr. Prichard, in entering upon the present discussion, (*On the Vital Principle*, 1829), “*Causas rerum naturalium non plures admitte debere, quam quae et verae sint, et earum phenomenon explicandis sufficient.*” (*Principia*, lib. iii).

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS,

FROM BIRTH TO PUBERTY,

BY DR. RYAN,

Delivered at the Medical School, Westminster Dispensary, Gerrard Street, Soho;

Session 1834-35.

LECTURE XXIX.

Hydrorachitis or Spina Bifida—Hydrocephalorachy, (Dropsy in the Brain and Spine)—Hydrencephalocèle, (Dropsy of the Brain and Scalp)—Congenital or Intra-uterine Ascites, Hydrothorax, Anasarca and Epiploric Dropsy—Hydrocele, (Infiltration of the Genital Organs, Mammæ, Cellular and Adipose Tissues), Sclérème (French), Skin-bound Disease (English).

GENTLEMEN—I have now to direct your attention to the nature and treatment of the remaining varieties of congenital dropsies. At our last meeting I gave you the history of congenital hydrocephalus; and I shall now place before you the pathology and treatment of hydrorachitis or dropsy of the spinal marrow, thus uniting the diseases of the cerebro-spinal organs.

The disease was first described by the Arabians, who supposed it to have arisen from a double set of spinous processes, and therefore called it spina bifida, or bifurcated spine. But it was first accurately described by Tulpius, G. Bauhin, Ruysch, Bonetus, Maurice Hoffmann, Morgagni, Camper, and Portal. Dissection has repeatedly shewn, that not only the spinous processes, but sometimes the rings of the vertebræ are deficient. Sauvages termed the disease hydrorachitis (*Nosol. Meth.*), Pinel, hydrorachis (*Nosog. Philos.*), and Frank, hydrorachia (*De Curat. Morb. Hom.*) In this country the ancient term, spina bifida, is, in general, still retained.

The term hydrorachitis is applied by some authors to a collection of serosity or serous fluid in some part of the spine, distending the skin; and spina bifida to a want of the vertebræ corresponding to the diseased part. Others have termed the latter disease spinal hernia, on account of the projecting tumour.

The disease called spina bifida in this country, consists of a fluid distending the membranes which envelope the spinal marrow or brain. It is generally congenital, and rarely occurs after birth. Otto has seen it so early as the sixth week of utero-gestation.—*Dict. de Med. et Chir. Pratq.* 1833.

It consists of a soft tumour, sometimes opaque, often transparent, red, or of a dark colour. It may be round or elongated, and hangs by a narrow neck. It is in general of the colour of the skin, but may be red, crimson, or black, and varies in size from that of a pea to that of a man's head in the adult, or an orange in the infant. Brunner describes

a case, in which the transparency of the tumour was so great, that the mother could see her figure and dress in it, as in a mirror.—*Miscel. Curios.* Dec. 3, cap. i. It varies in size, and may be as large as a man's head, as will appear immediately—a fact I can also attest. It is most commonly situated in the lower part of the back, or in the upper part of the loins; but it has been observed in the neck, different parts of the back, loins, and even at or near the coccyx. It was observed in the cervical region (Tulpius), at the base of the sacrum (Genga and Portal), on the last dorsal vertebra (Wepfer), and along the whole spinal column (Lechellius and Richard). In some cases there are two or more tumours, which are distinct, communicate with each other, or with the brain.—*Brewerton, Edinb. Med. and Surg. Journ.* vol. vii.; *Stafford on the Spine.* When the spinal dropsy communicates with the brain, the complicated disease is designated hydrocephalorachy—a term which signifies, dropsy of the brain and spine. In employing this and similar classical terms, I am aware that those who have not received a classical education may sneer at them as hard words, as such persons term them; but I would tell them that such are used by the most celebrated professors and writers in other countries: and I cannot comprehend the reason—indeed I am convinced there is none—why we should not be as classical as our neighbours. I believe this empire was never behind any nation in the civilized world, in learning, the sciences, or the arts; and it is only to be deplored that some illiterate and unclassical men should be placed, by chance, among our periodical writers, and be enabled to sneer at the classical terms generally adopted in every other part of Europe as well as in this country, except by such ignoramusses. I make this observation, as I shall have to employ terms in this lecture, which will astound these sapient critics.

The records of medicine affords many examples of this malady, in which fluid was found in the whole extent of the spinal column. Valsalva and Bidloo have described such cases. Capuron and Billard state, that the disease is often combined with hydrocephalus—a fact attested by numerous other authors. According to Duges, dropsies of the head and spine are the most common and remarkable of all the congenital dropsies. This accords with my own observation. This distinguished author divides them into four classes:—

1. Hydrocephalorachy, or complete cerebro-spinal dropsy, which distends and deforms at the same time the head and spinal canal.—*Ephemerides Medicales*, t. ii. p. 312.

2. Hydrocephalus, which fills and distends the cranium; a variety described at our last meeting.

3. Hydrencephalocèle (Corvinus), when some point gives way, and a

tumour is formed which communicates with the brain. Thus there are hydrencephalic, ethmoidal, frontal, bregmatic, syncipital, suboccipital, and supra-occipital tumours, or in other words, tumours of this kind may present on any part of the cranium; but especially on the anatomical regions above enumerated, and alluded to in the preceding lecture.

4. Hydrorachitis, or spina bifida, which has been just described.

Causes, Formation, and Progress.—The causes of congenital dropsies are increased quantity of blood in the affected part, a great quantity of amniotic fluid surrounding the infant in the womb, infiltration or dropsy of the parent, a hereditary predisposition to hydrocephalus, advanced age of the mother, venereal infection, &c. Burgius relates the history of a woman whose first infant was a well formed female, the second a male with spina bifida, the third another well developed female, and a fourth affected with spina bifida. The disease may be slow or rapid in its progress. Hydrocephalorachy is generally rapid in its development, and frequently bursts before the birth of the infant, or during parturition, when subjected to the pressure essential to that process (Geoffroy Saint Hilaire); but it ruptures most frequently during pregnancy, and there results a cranio-vertebral anencephaly, often with complete destruction of the brain and spinal marrow, sometimes these organs existing (*notencephaly*, &c.), the dropsy being internal in the one case, and external in the other. Whether the dropsy be internal or external, it is always contained in the arachnoid, which not only lines the ventricles of the brain, as demonstrated by Bichat, but also descends over the spinal marrow, and in the normal state incloses a small quantity of fluid (Magendie). But it is easy to conceive that adhesions or other mechanical obstacles may interrupt the cerebro-spinal communication, and circumscribe the collection of the fluid either in skull or spine. Dissection occasionally enables us to observe effusion of serum and blood in a circumscribed portion of the spine, without any lesion of the bones. Mr. Stafford describes cases in which the fluid was in separate cysts, and states that it is contained between the arachnoid membrane and pia mater (*Op. Cit.*) The spinal nerves of the affected part are altered (Tulpius, Burgius, Brunner, Morgagni, Camper, &c. &c.) The medulla has terminated in the tumour (Brunner, Hoin, Sandifort, Apianus). Hydrocephalus commences very near the period of conception, may advance rapidly, burst the cranium, and produce anencephaly or microcephaly; or it may continue until birth, and impede parturition: but in other cases it may not retard that process, and only develope in the first years of infantile life.

Hydrencephalocoele and other Cranial Tumours.

—Hydrencephalocoele may continue until the period of parturition; and it is to the intra-uterine rupture of this tumour we assign the formation of monopsy, apropsy, certain encephalocoeles (*prodencephaly*, *derencephaly* of Geoffroy Saint Hilaire).

It is very difficult to form a diagnosis between congenital tumours on the scalp, and hydrencephalocoeles. I well remember a case in which I was consulted in 1825, of a young lady aged eighteen years, well developed, menstruation being natural, who had a tumour on the superior part of the frontal bone, about the size of a breakfast tea-cup, capable of containing five or six ounces. I was informed that this was perceptible a few months after birth, and had gradually increased in size. It was not painful, nor productive of any inconvenience, but was considered a deformity. The bone appeared to be wanting round the base of the tumour; but on making graduated pressure, the size of the anormal production was not diminished. This was satisfactory evidence that the tumour did not communicate with the brain, notwithstanding the apparent absence of the frontal bone—that it was not a hydrencephalocoele—and moreover the excellence of the general health, and the period of life, which are unusual in the latter affection, warranted my conclusion. After a most mature consideration of all the symptoms and peculiarities of the case, I determined to puncture the tumour, and evacuate its contents. The bowels having been regulated, and a proper diet taken for a few days, I punctured it with a common lancet; about five ounces of a thick, gruel-coloured ropy fluid escaped, of a most offensive odour; there were no signs of cerebral depression or disturbance during the operation or evacuation of the fluid, and the pulse remained natural. On examining the frontal bone with a probe, it was found perfect, except depressed, as if absorption had taken place from the pressure of the suprajacent fluid. The supposed absence or depression of bone is a common symptom in extravasation of blood under the scalp; and this fact was not forgotten in forming the diagnosis. The sac having been fully evacuated, a weak solution of sulphate of zinc was injected; a compress was then applied and secured with a roller; cathartics were administered, and adhesion took place. Pressure was continued until the puckered integuments were so reduced by absorption, that it would be impossible for any one to suppose that a tumour had ever existed on the forehead. There was another peculiarity in this case, worthy of notice. The fluid was extremely offensive. A small quantity escaped on the floor, and the nauseating odour was so intense as to withstand the effects of pyroligneous acid, oil of turpentine, and ablution and was only removed by a solution of the

chloride of lime. This case will appear interesting, when contrasted with those of hydrocephalocoele which were treated by Richter, Grew, and H. Earle, and which I shall immediately notice.

Lastly, hydrorachitis may be ruptured before or during birth (*Tulpius Obs. Med.* 1685); or when small may remain entire on the newborn infant, and continue unbroken for several years. I have seen cases in which it was ruptured, and others in which it remained uninjured at birth. I was suddenly summoned, a few years ago, to attend a lady in her confinement, in the absence of her ordinary attendant. The parturition was natural, but the infant was born with a hydrorachitis in the lumbar region. The colour of the integuments was a deep crimson, the infant was not developed, and the tumour was the size of a racket-ball. My prognosis was unfavourable. Cold applications were employed, but the tumour burst on the seventh day; paraplegia followed, and the infant died on the twelfth day of its age. The tumour burst during parturition in two cases which fell under my observation. In the former variety, the spinal marrow was diminished or totally destroyed; and Duges met with an example in which it was cicatrized. The disease has been mistaken for an abscess, and opened.

Prognosis.—Hydrocephalorachy is generally mortal, whether it be ruptured before or after birth, on account of destroying by pressure and absorption the central parts of the nervous system, or the brain and spinal marrow; and it is speedily fatal when it remains entire at birth. There is a recent example observed in an adult, which was most probably an instance of extreme deformity of the spine caused by rachitism (rickets). Infants affected with this disease, generally die in a few days after birth.

When there is intra-uterine rupture of hydrocephalus, the foetus is destroyed; and in those cases in which hydrocephalic infants are born alive, viability is generally destroyed, though life may be protracted for several years. A variety of external causes, such as falls, blows on the head, or falls from a height on other parts of the body, may so concuss or shake the brain as to induce determination of blood to that organ, and render the original disease speedily fatal. The least fever, bad cough, hooping cough, teething, irritation in the bowels, will act in the same manner, induce congestion, coma, or convulsions, and death. Life may, however, be prolonged to an advanced age—thirty years (Van Swieten), thirty-five (Ekmark), fifty-five (Gall.) In cases of this kind the head gradually increases to an enormous size—36 inches in circumference (Monro), 880 millemetres* (Spurzheim),

920 in a girl aged two years (Lanetti), quoted by Esquirol, *Gaz. Med.* Jan. 24, 1835; Ryan's *Med. & Surg.* v. 7, 1835. The head contained thirty-six pints of fluid in Esquirol's case. It is worthy of remark that the head may cease to enlarge in some cases. Duges observed an instance in which the head was very large after birth, but it ceased to enlarge in the same proportions, and gradually approached the natural size, the intellectual faculties developed, and the infant assumed the erect position. The case now under treatment at the Western Dispensary, and mentioned in a late Clinical Lecture, is another proof of this fact. Hydrocephalocoeles, broken or unbroken, are generally mortal; but sometimes allow the infant to survive for some months, and even for twelve years (Spurzheim).

Prognosis and Pathology of Hydrorachitis.

—Hydrorachitis is generally dangerous, and mostly fatal. The disorganization of the spinal column and its contents, the separation of the vertebræ and the protrusion of the tumour, which is speedily irritated and inflamed by the dress and handling of the infant, predispose to rupture or gangrene, and when this last occurs, involuntary evacuations, paralysis of the lower extremities, and death speedily follow.

Nevertheless, life has been preserved to the tenth year (Bonn), to the adult age (Meckel),—and our museums contain casts of large spinæ bifidæ in full grown individuals. I have seen some casts representing cases much larger than the head of an adult.

Mr. C. Hutchinson describes a case of a young woman of nineteen; and Warner, a patient aged twenty. Mr. Jukes gives the history of a young female aged nineteen.—*Med. & Phys. Journ.* 1822. Mr. Stanley mentions in his lectures that he knows a case of an individual in the twenty-second year of his age.—*Stafford on the Spine*, 1832.

On examining the body after death, the spinous and transverse processes of the vertebræ are imperfect or destroyed, but the bodies of the bones are in most cases free from alteration. Firlez describes a case in which the whole spinous processes were wanting.—*Richter Chir. Bibl.* v. 9. There is sometimes a fissure in the bodies of the vertebræ, through which the intestines may be seen, and an adhesion of the bowel to this aperture has formed artificial anus, so that the fæces passed through the spinal tumor.—*Wepfer, Miscel. Cur.* Dec. 3. Saltzman, quoted by Mr. S. Cooper, in his *First Lines*, relates a similar case. The spinal marrow, if it exist, occupies the anterior part of the tumour. Senac observed, that the fluid contained in the tumour communicated with the ventricles of the brain, while Lancisi, Mayer, and Brunner, remarked that when it escaped, the size

* Millimetre is computed by Dr. Ure at .03937 English inches. The admeasurement

is here about 37 inches in one, and nearly thirty-eight in the other.

of the head diminished. Morgagni relates a case in which pressure on the tumour was distinctly felt by the hand placed on the fontanelle, and pressure with the hand so placed caused the fluid to descend, and distend the tumour.—*De Sed. et Caus. Morb.* 12. Bertrandi reports a similar example.—*Opere di Ambrogio Bertrandi.* t. ii. See also Brunner *Op. Cit.*, Mayer, Bonetus, Genga, Dubruil, *Ephemerides Medicales*, Pecklin, Sandifort, *Dict. de Med. & Chir. Prat.* 1833. Keilman *Prodom. Act. Havn. &c. &c.* Others have attested this observation; and the fact disproves the opinion maintained by B. Bell, Rosen, Lassus, and Bodin, that spina bifida was confined to the spine alone. It also shews the incurability of the disease when connected with the brain. There are cases in which the fluid was encysted between the membranes and spinal cord, and these have been cured. Thus, a thread passed through the tumour, in the form of a seton, has been followed by complete success—(Hoffman, Cooper, Earle, Bozzeti). This plan was first proposed by Bodin and Dessault. Camper, Maurice, Hoffman, relate one case each, cured by puncture, an operation revived in this country, by Mr. Abernethy, but found to fail. Sir Astley Cooper related one case in which repeated puncturing the tumour with a needle, and moderate pressure, effected a cure.—*Med. Chir. Trans.* v. 2. (A full account of Sir Astley's cases will be found in Cooper's *Surgical Dictionary*.)—The object was to evacuate the tumour by puncturing it repeatedly, and to excite adhesive inflammation, so as to cure the disease. This could only succeed when the disease is circumscribed and remediable. Mr. Earle relates a case of occipital hydrocephalocele, which he repeatedly punctured with a common needle; ulceration at length set in, and the child rapidly sunk.—*Med. Chir. Trans.* v. 7.—Richter relates a similar case (*Chir. Bibl.*)—Grew and others state, that the tumour had subsided by the efforts of nature, or by artificial means; but that hydrocephalus supervened, and speedily proved fatal. Strong compression, a free opening into of the sac, the application of a ligature, have been rapidly succeeded by death. Mr. B. Bell was the first who proposed a ligature, but it does not appear that he had ever employed it. But moderate compression of the tumour, and a simple protection from external injury, have preserved life to an advanced age—to fifty years (Meckel).

Genga and Camper state, that a spina bifida complicated with hydrocephalus, was cured by the rupture of the spinal tumour. This was seated near the coccyx.

When the infant affected with spina bifida is premature or delicate, it seldom survives, and is usually destroyed in a few days after the rupture of the tumour, a fact I have mentioned already. When there is natural development, the prognosis is much more

favourable. But when we consider the inconstant motion of infants and children, we must see the great liability there is of irritating or inflaming the tumour; and therefore, the prognosis in all cases must be given with caution.

Before leaving this topic I may briefly enumerate other malformations of the medulla spinalis, or spinal brain: numerous specimens of which are preserved in our museums; and M. Ollivier has cited numerous authors, and related several cases of each variety, which had fallen under his own observation.—*Traité de la Moelle Epinière*.—The malformations are as follow:—1. Total absence of the medulla spinalis. 2. A total want of the nervous system. 3. A simultaneous absence of the brain and spinal marrow. 4. An imperfect state of the latter. 5. A division of the marrow into two halves of a greater or less extent. 6. A double formation of the spinal marrow. 7. A variety in its length and thickness, and of a central cavity in its substance.

The absence of the spinal cord, amylic is ascribed by many of the most celebrated physiologists to an arrest of development (Bec-lard, Meckel, Ollivier, Duges, Geoffroy Saint Hilaire, Billard, &c.) The brain is also wanting in such cases. This confirms the modern view of development. The ancients followed Galen in supposing the spinal marrow was an appendage to the brain. Plato, Praxagoras, and Philotine, believed that the spinal marrow was formed before the brain, a doctrine revived by Gall, and proved by Tiedemann. It is now the received doctrine, that the spinal marrow is formed before the brain, and that this last is only an expansion of it. According to this conclusion, if the spinal marrow be absent, the brain must be absent also; and this is invariably the case.

Congenital Ascites, Hydrothorax, and Anasarca.—Dropsy of the abdomen or ascites has existed in the fœtus in utero, and impeded parturition. Obstetric writers cite examples of this kind. Two remarkable cases of recent date may be quoted. MM. Billard and Duges have recorded cases of acute and chronic peritonitis of the infant during intra-uterine existence; and it is as reasonable to admit such reports, as those of inflammation in the brain, lungs, or any other part.

Baron Roux relates the following remarkable case of intra-uterine ascites, hydrothorax, and anasarca. A pregnant woman, aged thirty years, fell from a height upon her abdomen, and the effect was a general commotion in the lumbar and hypogastric regions, which was followed by strangury. A month afterwards she was taken with labour, which was impeded by the size of the bladder, which it was necessary to puncture. Six pints of fluid escaped by the canula, and finally by the natural passage. She was the

livered of a dead infant. On opening its body, there was nearly a pint of fluid found in the abdomen and chest, and the cellular tissue was the seat of general infiltration. All parts of the body, both internal and external, were well developed, and there was no tendency to mortification.—*Journ. de Med. Chir. et Pharm. par A. Roux*, t. xvii.

I have met with three similar cases.

Congenital Epiploic Ascites.—*Partial Anasarca.*—M. Ollivier (d'Angers) relates the following singular case, which is perhaps unique. A woman, who always enjoyed good health, was delivered at the eighth month of ptero-gestation of a dead infant well formed. I was struck, says the narrator, at the enormous size of the abdomen, whose parietes were so thin as to enable me to see the transparent fluid which distended it. On dividing the integuments, some cupsful of yellow transparent serosity escaped, the peritoneum was white, and without any injection. The lower part of the abdomen was filled by a transparent tumour formed by the great epiploen which contained a yellowish, limpid serum, in which flocculi of lymph floated. Was this the result of epiploitis?—(*Arch. Gen. de Med.*, t. vii, p. 383.) Mauriceau, Portal, and a host of others, describe ascites in the fœtus in utero. Analogy warrants the conclusion, that hydrothorax or dropsy in the chest, may also exist. The case of M. Roux, and those witnessed by myself, prove that universal anasarca may be congenital.

There may also be partial œdema or dropsy. An infant is born with the integuments of the scrotum infiltrated; the nurse soon detects this disease, and directs the attention of the medical attendant to it. She states, "there is something amiss with the purse." This dropsical infiltration may extend to the penis and prepuce. We also occasionally observe female infants with infiltration or swelling of the labia and nymphæ (external genitals), as congenital affections. The repeated application of cold water, camphorated spirit and water, solutions of acetate of lead or muriate of ammonia very speedily remove this disease. The last form of congenital dropsy is termed *hydrocele*. This disease was first described by M. Viguerie, a distinguished surgeon of Toulouse. It is common to new-born male infants. It consists in a tumour on one side of the scrotum, caused by a collection of fluid in the closed sac, tunica vaginalis, or continuation of the peritoneum, (a serous one, like those in the head, chest, and abdomen). The inguinal canal which affords a passage to the testicle is generally obliterated at birth, but may also allow the descent of the serous fluid accumulated in the abdomen. It is to be recollected that the peritoneum or membrane which covers the parietes or walls of the abdomen and bowels, and contains the fluid in dropsy of the abdomen, descends into the scrotum and forms a bed for each testicle.

In general, when the testicles descend at

each side, the femoral rings or openings in the groins which allow them to pass are soon closed; but this does not always happen. Fluid from the peritoneal membrane, may therefore pass into the scrotum, and this part will be swelled on one side, seldom on both. But the disease often exists in the absence of all signs of dropsy. The femoral rings may be obliterated in the new-born infant as well as in the adult; and in such cases the hydrocele will be local and contained in the tunica vaginalis, without the possibility of pressing it into the abdomen. There is no danger whatever to be apprehended from hydrocele. The repeated application of cold water, or lotions, which are better, will very speedily remove it. M. Capuron advises pressure, so as to force the fluid into the abdomen; but according to my experience, cold will effect a cure. M. Duges seems disposed to recommend a small puncture; but I never met with a case of hydrocele in which it was necessary. If cold applications fail, the scrotum being suspended in male infants, we may in general expect a cure after the use of some of the preparations of iodine. My distinguished correspondent, Professor Dewees, recommends pouring two quarts of cold water through the pipe of a tea-kettle, from a height, over the tumour. But I have repeatedly known hydrocele cured by pouring half a pint of cold water through the pipe of a teapot. It is scarcely ever necessary to puncture. If the application of cold had failed, I should try a weak solution of iodine, such as Lugol's mineral water, as I have lately cured two cases of the disease in the adult by this remedy. Both patients were treated at St. John's Hospital, and seen by several students.

Congenital Infiltrations of the Genital Organs.—Infants are sometimes born with swelling of the scrotum in the male, and also of the external genitals in the female. This swelling is caused by infiltration of the cellular tissue, and tumefaction of the scrotum is sometimes caused by pressure during parturition in gluteal or breech presentations. In delicate infants, or those kept too warm, the scrotum may be relaxed—but this is no sign of weakness; it is caused by the heat of the napkin, and disappears on the application of cold water. If it did not disappear on the use of cold, and was always constant, then it would be indicative of disease or debility. Infiltration, or swelling of the scrotum, unaccompanied by redness, heat, and pain, is rapidly removed by the use of cold water or lotions. It usually disappears in a few days, without any medicine. The application of cold water at the time of ablution, whenever the infant soils itself, is generally effectual. In some obstinate cases, solutions of acetate of lead, muriate of ammonia, &c., are required. It would be right to advise the nurse to suspend the scrotum, or raise it towards the abdomen, which is easily effected

in applying the napkin about its hips and thighs.

Congenital Tumefaction of the Mammae.—The mammae or breasts of infants of both sexes are generally swollen at birth. The colour of the skin is natural or reddish. Mothers and nurses often inflict great injury by attempting to squeeze out the milk, as they term it, which they erroneously imagine is the cause of the swelling. Gentle suction, or friction with olive or almond oil applied night and morning, usually removes the disease. The application of a sponge, dipped in cold water in summer, and tepid in winter, when the infant is stripped, night and morning, will speedily remove this disease. If inflammation appears, the skin being hot, swelled, and painful, warm poultices must be employed. I have been frequently requested to visit infants who were constantly screaming, without any evident cause; but on stripping them, an abscess of the breast, varying from the size of a walnut to that of a pullet's egg, was discovered. Severe pain was excited whenever the infants were moved; and also by the pressure or friction of the dress. On opening the abscesses, immediate relief was produced.

Lastly, there is sometimes a serous discharge from the navel, after the separation of the remains of the umbilical cord, about the fifth day or later; and is mostly caused by a very small fungus. It is speedily removed by a saturated solution of alum, or a little red precipitate, or moderate pressure. The application of nitrate of silver is effectual, but should not be tried until ordinary remedies have failed. Some practitioners advise a ligature, but this is rarely necessary.

Congenital Dropsical Induration—Sclérème (Skin-bound).—There is also another kind of swelling in all parts covered by skin, occurring during the first eight days after birth, which M. Chaussier, an eminent French professor, has termed *Sclérème*, but which was first described in 1718 by Uzembesius of Ulm. The best description of it given in this country was by Drs. Denman and Underwood, and the best in France by M. Andry. It was ascribed by Underwood and Doublet, of Paris, to syphilis, erysipelas: was first accurately described by Andry, whose researches were the foundation of two successful memoirs by Auvity and Hulme, which were awarded prizes by the Royal Society of Medicine of Paris.

According to these authors, Underwood and Chambon, the disease attacks robust as well as feeble infants, whether nursed by the mother or a stranger. The disease is most common in winter, a fact also attested by Billard. It is often observed in Lying-in and Foundling Hospitals, as well as in private practice. It was termed *œdematic concrete* by M. Souville, of Calais. It may be general or partial. It is an induration which, according to MM. Baron and Billard, ought

to be classed among the dropsies of the cellular tissue or *œdemata*. It is caused by cold (*Troceon*) in the superior and inferior extremities, and may also attack the integuments of the chest and abdomen. The diseased parts are swollen, tense, and hard, of a violet colour, and retain the impression of the finger, or pit on pressure. Hulme states there is inflammation—it is sometimes followed by the species of tetanus termed *trismus*, locked-jaw, and *opisthotonos*, or bending of the body backwards. *Dyspnoea* supervenes, the voice becomes whispering, the thorax renders a dull sound on percussion, and the infant dies on the fifth or seventh day of the disease (Andry). It sometimes happens that the induration or hardening is dispersed by proper remedies, but that the *œdema* remains; and this is generally dissipated in fifteen or twenty days. In some cases the part inflames or suppurates (Gardien); fever follows, and the infant is destroyed in twelve or fifteen days (Hulme).

Congenital Concretion of the Cellular Tissue.—There is another form of this disease which deserves attention: it is what M. Chaussier terms the *concrete form*. The cheeks, limbs, fore arms, legs, abdomen, and thorax, become as hard as a tanned hide, or wood; they do not pit on pressure, and are as cold as ice. The skin is pale, yellow, or livid. The *trismus*, *opisthotonos*, feeble cries, moans, or whisperings, are more marked than in the former disease. The appetite and digestion are good for some time, but soon fail; and then green stools are observed, the strength is greatly reduced, and the infant is unable to suck. It speedily dies in a state resembling asphyxia, without emaciation; but if judiciously bled, it gradually loses the hardness; the tetanus is cured, unless pneumonia supervene after the disappearance of the *sclérème*, or original disease. It is important to know, that local inflammation is rarer in this than in the former species. M. Duges states, that he has sometimes observed suppuration follow, and an abscess communicate with the knee joint. It commonly happens, that *icterus* or jaundice generally accompanies this second form of *sclérème*.

The autopsy, or dissection after death, enables us to see the cellular tissue infiltrated with serosity in the first variety (Andry); it is also hard and concrete in the other species (Hulme and Marzari). There is a sanguinolent effusion in the brain; the *foramen anale* is more open than usual (St. Leger), the intestinal canal is shorter (Breschet,) or inflamed (Denis), &c. The disease may exist without these symptoms, or the symptoms may exist without the disease (Duges). This last able author informs us, that he has observed the brain congested, and the cerebellum covered with a slight layer of lymph—(arachnitis). He also found the stomach intensely inflamed; and in winter, hepatization of the lung, or pleurisy—diseases also ob-

served by Hulme and Marzari. But he has seen the disease in other winters, without these complications.—*Manuel Obstétrique, &c. Deuxième Edition, 1830.*

The best account of this disease I have met with, is that of M. Billiard. After an able analysis of the writings of Duges, Denis, Andry, Auvity, Breschet, Chevreuil, Hulme, Underwood, Baumes, Paletta, Leger, and others, he draws the following conclusions:—

1. Induration of the cellular tissue of new born infants, is a simple œdema, like that of adults. It may be local or general; it ought to be distinguished from œdema of the adipose tissue.

2. It is more common in winter than in summer, and more frequent in new born infants than those more advanced in age; and has for its predisposing causes—1. a natural feebleness; 2. a general and congenital plethora; 3. a superabundance of venous blood in the tissues; 4. a dryness of the skin before exfoliation: its direct causes are—1. an obstacle to the circulation of the blood, on account of the abundance of this fluid in the circulatory apparatus; 2. its engorgement in the cellular tissue, to which it furnishes too much materials for secretion; 3, and in fine, the action of external agents on the skin, which, without condensing the serous fluids, as it is said, are capable of suspending cutaneous transpiration, and of favouring the accumulation of serosity in the cellular tissue. Sanguineous infiltration of the liver, lungs, or heart, the persistance or occlusion of the foetal apertures, are not the exclusive and indispensable causes of this affection; we should only consider them as concomitant phenomena—as accessory circumstances.

3. When the œdema is general, and the serous congestion is extreme, all parts of the cellular tissue may have their functions disturbed. Then the glottis may become œdematous, the lungs congested, and the cries of the infant become feebly shrill and impeded. The condition of the circulation easily explains the coldness of the extremities, and the prostration or enfeeblement of the patient. It also explains the other symptoms described by authors.

4. The indications of treatment are—1. to combat, by sanguineous evacuations, general plethora; 2. to excite the skin by irritating frictions, woollen clothing, and vapour baths, so as to establish cutaneous transpiration. M. Baron prefers frictions and woollen clothing to vapour baths, which often cause pulmonary and cerebral congestion. M. Billard has observed the best effects from woollen clothing. He states that the disease is not necessarily fatal, unless complicated with affections of organs essential to life.—*Traité des Maladies des Enfants, &c., Deuxième Edition par M. Ollivier, Paris, 1833.*

Treatment.—In addition to the preceding remedies, the milk of a healthful nurse and vapour baths are perhaps the best remedies.

Six or eight baths, at the temperature of 85° or 90° every day, have been employed with advantage. The infants are often in good health, and have a good appetite. Woollen clothing is also indispensable; warm and medicated baths are also useful. Dry vapour baths are seldom sufficient. Andry advised blisters, but these are inadmissible when the skin is inflamed, and are only justifiable in pure œdematous, or concrete sclérème, after all other remedies have failed. Gardien and Lasses recommended fumigations of gum ammoniac dissolved in vinegar, thrown on red-hot iron or live coals, the parts being enveloped in wool. This remedy was first proposed by Galen and the Greeks, and a modification of it is even yet employed in indolent swellings. But the resolvent power of the following remedies is much greater. When inflammation exists, leeches and ordinary antiphlogistic remedies should be employed. When the disease becomes chronic, and inflammation is absent, stimulating liniments, iodine, frictions and baths, moxas, and blisters, as in chronic phlegmasia dolens are advisable. An ointment composed of a scruple of proto-ioduret of mercury, or ioduret of lead, to an ounce of simple cerate, rubbed on the affected parts, in the proportion of a drachm night and morning, would most probably excite absorption. Some of the iodureted preparations, and the means used in dropsies, might be employed, at the same time, with advantage. It is always to be remembered, that there are some cases wholly incurable.

—o—

A NEW PRACTICAL FORMULARY OF HOSPITALS, OR A

Collection of Formulæ of the Civil and Military Hospitals of France, Germany, Italy, Great Britain and Ireland, &c., containing the Indication of the Doses in which simple Substances, magistral and officinal Preparations of the Codex are administered, the use of New Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M. D., and P. VAVASSEUR, M. D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M. D. &c. &c.

(Continued from p. 143.)

DIURETICS.

Pariétaire.

The diuretic effects of this substance are not very active. It was formerly much used in inflammatory affections of the urinary organs.

INTERNALLY.—Decoction manip. j—Oij of water.

The *Decoction de Pariétaire* of the Hot. D. contains \mathfrak{z} j of the plant to the above quantity of liquid.

Distilled water of Pariétaire. P. \mathfrak{z} ij— \mathfrak{z} iv as a vehicle for diuretic potions.

EXTERNALLY.—Decoction in enema.

Enema of Pariétaire. H. de la Ch.

Rx. Pariétairæ, 3 ss;
Aquæ, Oj.
Coque, cola, et adde,
Potassæ acetatis, 3j.
Fiat enema.
Employed in dropsies.

UVA URSI.

A diuretic. Much used in calculous complaints, and ulcerations of the urinary organs, gonorrhœa, &c.

INTERNALLY.—*Powder.* ʒj—3j. Not much used.

Infusion and decoction. From 3ij—iv in Oij of water.

Decoction of Uva Ursi. H. of Germ.

Rx. Uvæ ursi, 3 ss;
Theræ, 3j;
Acaciæ veræ, 3j;
Aquæ, 3ij.
Coque, cola, et adde,
Mellis, 3vj.

Hujus decocti sumat cochleare magnum quater, vel sexies, in die.

Diuretic Infusion.

Rx. Uvæ ursi,
Baccarum juniperi, ā ā 3 ss.
Macerā in aquæ ferventis, Oij.
Cola, et adjice,
Syrupi simplicis, 3ij.

Fiat infusum, cujus sumat cochleare amplum ter in die.

Lithontriptic Powder. H. of America.

Rx. Pulveris uvæ ursi,
— — — cinchonæ, ā ā 3ij;
Opīi, gr. iij.

Divide in chartulas vj, quarum sumat unam ter, quaterve in die.

3ij of lime-water should be taken immediately after each dose.

PARSLEY (ROOT).

A slight diuretic, united sometimes with other substances which possess the same qualities.

INTERNALLY.—*Decoction.* 3 ss—j in Oij of water.

Diuretic Decoction.

Rx. Radicis petroselini, 3i;
Seminum dauci sylvestris, 3ij;
Parietaræ, 3 ss;
Aquæ, Oiv.
Coque, ad dimidium, cola, et adde,
Potassæ nitratis, 3j.

Hujus decocti, cyathus pro dosi sumendus.

The roots of small-age, pariera-brava, the caper-tree, wild carrot, and others of the same species, possess slight diuretic properties, and may be employed in the same cases as the preceding substances, in infusion or decoction, in doses of 3ij—iv, in Oij of water.

The *Espèces Diuretiques* of the *Code* are

composed of equal parts of the following ingredients:—

Rx. Radicis fœniculi,
—— musci,
—— asparagi,
—— petroselini.

The dose of this mixture is 3j to Oij of water, either in infusion or decoction.

CHAPTER VI.

MEDICINES WHICH ACT PRINCIPALLY UPON THE CUTANEOUS SYSTEM—DIAPHORETICS, &c.

SULPHUR.

INTERNALLY, in large doses, this substance is a purgative; in smaller ones it is a general stimulant, exercising a special influence on the cutaneous system. It is used as a general stimulant in certain cases of scrofulous swellings, œdema, catarrhs, and paralysis produced by mercurial or saturnine vapours. Its action on the skin is considered as very useful in scabies and other cutaneous affections. It is also used externally in a great number of diseases of the skin.

[It is said to be the best remedy for painters' colic. T.]

INTERNALLY.—As a purgative, the dose is 3i—iij in milk or an electuary.

As a stimulus, grs. xij—ʒj twice or thrice a day.

Pustilles Soufreés, P. 3j—iv. Employed principally in scabious affections.

Tablettes de Soufre Comf. P. 3 ss—ij. Used in the same cases.

Baume de Soufre. P. gutt. x—xx. Not often used internally.

Baume de Soufre Anisé. P. gutt. v—x.

Antipsoric Powders. H. of Germ.

Rx. Sulphuris,
Glycyrrhizæ, ā ā 3vi;
Camphoræ, 3 ss.

Divide in chartulas xij, quarum sumat duas quotidie.

Diaphoretic Powders. H. of Lyons.

Rx. Sulphuris, 3iv;
Camphoræ, ʒi.

Fiant pulveres xij quarum capiat unam vel duas in die ex cyathothecæ.

Anticatharrhal Powders. H. of Germ.

Rx. Sulphuris, 3ij;
Potassæ supertartratis, 3vi;
Sulphuris antimoniatī fuscī, gr. xv.

Divide in chartulas xvj, quarum capiat unam quartā quaquā horā.

In chronic pulmonary catarrh.

Antipsoric Boluses.

Rx. Sulphuris, 3j;
Saponis medicinalis, 3 ss;
Syrupi gentianæ, q. s.

Fiant boli iv é quibus sumat unum mane nocteque.

Sulphur Bolus. H. Militaires.

Rx. Sulphuris, gr. viij;
Mellis, q. s.

Fiat bolus.

Compound Bolus of Sulphur. H. Militaires.

Rx. Sulphuris;
Pulveris anisi, ā ā gr. viij;
—— sennæ, gr. iv;
Mellis, q. s.

Fiat bolus.

Boluses used in Inflammation of the Bladder.
H. of Italy.

Rx. Sulphuris, 3j;
Olei terebinthinæ, ʒij.

Divide in bolos sex, ē quibus, capiat j
tertiā quaquā horā.

Sulphuretted Opiate. H. of Paris.

Rx. Sulphuris, partes tres;
Mellis, partem unam.

Misce 3ss—j capiat quotidie, vel bis in
die.

Laxative Electuary.

Rx. Sulphuris, 3iv;
Confectionis sennæ, 3iss;
Syrupi rosarum, q. s.

Fiat electuarum cujus capiat cochleare
minimum ter quaterve in die.

Sulphuretted Potion. H. of Germ.

Rx. Sulphuris, 3ij;
Aque fœniculi, 3iij;
—— cinnammomi, 3j;
Syrupi papaveris, 3ss.

Fiat potio, cujus detur cochleare unum
omni horā.

In diabetes. The bottle should be well
shaken each time the medicine is administered.

Expectorant Loach. H. of Germ.

Rx. Sulphuris, 3j;
Sacchari, 3ij;
Olei lini, 3j;
Syrupi toluiferæ, 3jss.

Misce. Dosis cochleare, magn. bis in die.

Administered in catarrhs of long standing.

EXTERNALLY.—In lotions, 3j—Oj dis-
solved in Oʒ of water.

Onguent Soufré pour la Gale. P. Much used
in scabies.

Onguent Soufré Alcalini. P. In the same
cases.

The *Pommade Sulfuro Alcalini* of the H. St.
L. does not differ from the preceding pre-
paration.

Antipsoric Powders. H. de la Mat.

Rx. Sulphuris,
Plumbi acetatis, ā ā 3j;
Zinci sulphatis, 3ss.

Misce.

A small quantity of this powder, with a
few drops of oil added, is used in frictions
on the palms of the hands morning and
evening. It is very convenient in the
treatment of scabies, as by its use the bad
odour, &c. of other preparations are avoided.

Lotion Sulphuro-Savonneuses. H. St. L.

Rx. Sulphuris,
Saponis duri, ā ā 3j;
Aque, Oʒ.

Liqua saponem in aquā, cola, et adjice
sulphurem.

Employed with success in the treatment of
scabies; it sometimes produces red spots or
pimples, which soon disappear by discontinuing
its use.

Sulphuretted Cerate. H. of Eng.

Rx. Sulphuris, 3iv;
Cerati simplicis, ʒbj.

Misce.

Used in frictions in scabious affections.

The *Onguent Soufré* of the H. des Ven. con-
tains double the quantity of sulphur.

Pommade used in Scabies. H. St. L.

Rx. Sulphuris, 3v;
Potassæ subcarbonatis, 3ij;
Aque, 3j;
Olei olivæ, 3iv.

Liqua potassam, adjice oleum et deinde
sulphurem.

Used with success as an antipsoric; it has
the advantage of not soiling the linen, and has
no odour. It generally effects a cure in thir-
teen days.

Pommade Sulphuro-Savonneuse. H. St. L.

Rx. Sulphuris,
Saponis albi, ā ā ʒbj.

Liqua saponem in aquā, cola, et adjice
sulphurem.

Used with success in scabies; it does not
soil the linen, and effects a cure in ten days.
The red pimples these frictions occasion gene-
rally yield to the use of tepid baths.

Antiherpetic Pommade. H. de la Ch.

Rx. Sulphuris, 3ij;
Hydrargyri submuriatis, 3j;
Adipis, 3j.

Misce.

Employed with advantage in herpes.

Pommade used in Tinea Capitis. H. de Mont.

Rx. Sulphuris,
Pulveris carbonis ligni, ā ā 3ij;
—— sennæ,
—— cinchonæ, ā ā 3j;
Cerati simplicis, q. s.

It is used as an unction for the head.

SULPHURIC ACID.

When respired in a large quantity in a
gaseous state, it causes instant death; in
smaller quantities, it irritates, in a lively
manner, the respirative organs: applied to
the skin, it stimulates that membrane, and
is employed with success in cutaneous af-
fections. Dissolved in water, it is some-
times administered as an astringent and sti-
mulant. It is used externally in lotions, in
diseases of the skin and atonic ulcerations.

INTERNALLY.—Dissolved in water, gut.
xx—lx in Oj of vehicle.

Baths of the Vapour of Sulphur:

The patient is placed in a box, the head

uncovered, into which the vapour arising from sulphur, placed upon a piece of iron made red hot, is introduced. The quantity of sulphur generally employed is ʒ ss.

SULPHATE OF POTASSA.

An energetic stimulant. In large doses it is a violent poison; in small ones, it is a stimulant of all the organs, but more especially of the skin, the lungs, and the organs of circulation. It is employed in cases of chronic cough, obstinate hooping-cough, the croup, chronic rheumatism, &c., but especially in obstinate tetters. It is used externally in herpetic, scrofulous, and rheumatic affections.

INTERNALLY.—Gr. vi—xviiij in Honey, or in pills with soap.

Sirop. P. ʒ ij—ʒ j, and even ʒ ij; each ounce contains about gr. xij of sulphur.

The *Sirop de Sulfure de Potassæ* of the H. de la Mat. contains about half the above quantity of sulphur.

Sulphuric Potion. H. of Germ.

℞. Potassæ sulphatis, ʒ j;

Aquæ, Oj;

Sacchari, ʒ ij.

Fiat potio cujus capiat cochleare magnum.

Recommended in poisoning by arsenic.

Pills of the Sulphate of Potass.

℞. Potassæ sulphatis, gr. xv;

Saponis medicinalis, ʒ j;

Balsami peruviani, q. s.

Fiat massa, in pilulas xxx distribuenda, ex quibus sumat ij, quartâ quaquâ horâ.

Employed in cutaneous affections; also recommended that a cupful of the hot infusion of juniper berries be taken a quarter of an hour after them.

Pilules de Charbon Alcalines. H. of Germ.

℞. Potassæ sulphatis, ʒ j;

Extracti cardui benedicti,

Pulveris carbonatis ligni, aa ʒ ij.

Fiat massa, in pilulas gr. ij distribuenda, quarum sumat xv—xx, quater in die.

In pulmonary phthisis.

Each pill contains gr. jss of sulphur.

Boluses used in Mercurial Salivation. H. of Italy.

℞. Potassæ sulphatis, gr. iij;

Succi sambuci, q. s.

Fiant boli sex, quarum sumat unum, tertiâ quaquâ horâ.

Powders used in Mercurial Salivation.

℞. Potassæ sulphatis, ʒ iv;

———— supertartratis, ʒ iv.

In chartulas xxiv, divide quarum sumat unam bis in die.

Each packet contains gr. iv of sulphur.

EXTERNALLY.

Liniment Sulfuro-Savonneux. H. des Enf.

℞. Potassæ sulphatis, ʒ iij;

Saponis duri,

Olei olivæ, aa ʒ ij;

— thymi, ʒ j.

Dissolve the sulphur in a third of its weight of water, liquefy the soap in a sea-bath, and add the oil by degrees; mix the whole well together.

Employed as an antipsoriac, and in the treatment of several other cutaneous affections.

Pommade used in Tinea-capitis.

℞. Potassæ sulphatis,

Sodæ subcarbonatis, aa ʒ ij;

Adipis, ʒ viij.

Misce.

The head should be rubbed daily with this pommade, the hair having been cut and removed by cataplasms; it should then be covered with blotting paper. When the pommade does not act with sufficient energy, the quantity should be increased.

Sulphur Baths of Bareges. H. of Paris.

℞. Potassæ sulphatis, ʒ iv;

Aquæ, Occ.

Employed daily in diseases of the skin, certain nervous affections, &c.

The *Bain Sulfureux* of the H. des Enf. only contains half the above quantity of sulphur.

The *Bain Antipsonque* of the H. of D. contains a pound of sulphate of potass. This is one of the numerous means employed in the treatment of scabies.

The sulphate of soda possesses the same properties as the sulphate of potassa, but it is not so active. It is not often used.

The sulphate of lime is not used in France, but in Germany it is employed in the same cases as the preceding substances. It is frequently preferred for the preparation of sulphurous baths, on account of its cheapness. It is administered internally in doses of grs. iv ad xij.

HYDROSULPHURIC ACID.

When respired in a large quantity, it causes instant death. Externally, it is an energetic stimulant of the skin, and is employed in diseases of that tissue.

—o—

Review.

Traité des Hémorrhagies Internes De l'Uterus, &c. Par A. C. Baudelocque, M. D., &c. Bruxelles, 1832. *Treatise on Internal Uterine Hæmorrhages.* By A. C. Baudelocque, M. D., &c. Brussels, 1832.

This work is constructed on the principle of the *clinique*—the best possible form for practical books on medicine, and which it were to be wished that British medical authors would more frequently adopt, to the exclusion of those mystifying generalities, which may be very true for ought anybody knows to the contrary. The merits of M. Baudelocque, as an obstetrical practitioner and writer, are sufficiently known to render

commendation unnecessary; the work before us was, moreover, honoured with the prize of the Parisian faculty of medicine in 1819; we shall, therefore, make this article rather a collection of excerpts than a critical review. The first chapter treats of the several situations in which internal uterine hæmorrhage may occur.

I. During the period of gestation blood may be effused.

1. Between the uterus and epichorion; this is the most frequent cause of abortion in the earlier stages of pregnancy.

Case.—A woman of a nervous temperament, four months and a half gone with child, perceived that her urine was mixed with mucus slightly tinged with blood; her health in other respects being perfectly good. This appearance could only be attributed to repeated sexual intercourse immediately previous to its occurrence. A small bleeding from the arm was practised, and absolute rest prescribed. Every thing went on well till the end of the sixth day; during the night of the seventh, labour pains came on, and the ovum was expelled at the end of six hours. The child was alive. The placenta was five inches long, by two inches broad, and the inferior third of its uterine surface was covered with a very solid layer of black blood, from eight to ten lines thick. (*Journal Gén.* t. 68, p. 339).

2. Between the epichorion and chorion.

Case.—The Countess ———, aged 28, having been married six years, had a miscarriage, soon after which she again became pregnant. The day on which the menses should have appeared she experienced severe colic pains, which continued from seven to eight weeks, notwithstanding the observance of complete repose. Frictions of ice on the lumbar and sacral regions were used without success. Five days after the third menstrual period, it was determined to practise venesection, since the colic pains were now attended with external hæmorrhage. Abortion took place at the expiration of forty-eight hours. M. Deneux, who was now called in, examined the product of conception, and found, beneath the epichorion, a layer of coagulated blood of a very high colour, a line and a half thick at the sides, and five or six at the two ends. The embryo was of the size of a fly, and was be-

lieved to have died six weeks after conception. (*Journal cité*, t. 68, p. 355).

In this case extravasation of blood must have taken place round the ovum at the time when the colic pains first occurred, at which period, also, the foetus ceased to live, as evinced by its state of development. The pains, occasioned at first by the menstrual turgescence, were afterwards kept up by the distention of the effused blood; or, the extravasation may have already taken place at their commencement. "It is difficult to conceive," observes M. Baudelocque, "with what intention the frictions with ice were used—there was doubtless some error of diagnosis."

3. Between the chorion and amnios; of which no cases are detailed, but the author states that Professor Deneux has shown him several distinct examples, and that Dr. De Kergaradec found a fibrinous concretion between the chorion and amnios, near the insertion of the umbilical cord into the placenta.

4. Between the placenta and the uterus; of which the first case cited in this article may serve as an example: the following is a fatal instance of a similar accident.

A woman thirty-six years of age, who had borne several children, was troubled, in the eighth month of pregnancy, with violent cough and fever, which continued for several days. Labour-pains came on, and after twelve hours, the midwife who was in attendance observed the patient to fall into a alarming state of syncope. M. De Laforterie was called in, but the patient died before his arrival. He performed the Cæsarian operation. On opening the fundus of the uterus a pint and a half of black uncoagulated blood gushed out, which had been contained in a cavity formed between the placenta and fundus uteri, the middle of the placenta having been detached, while the adhesion of the margin remained firm. No trace of blood was found in the vagina, and the os uteri was little dilated. The child was extracted alive, but soon died—*Journ. Gén.* t. 29. p. 384.

Some of the vessels passing between the uterus and placenta appear to have been ruptured during the fits of coughing. The pains must have been caused by the distension of the womb, since the state of its ori-

fice and of the regimen shows that real labour had not commenced. The fact of the child's being alive proves that the blood came from the uterine not the placental vessels, and also that its extravasation was recent.

5. Between the uterus, placenta, and external surface of the tunica decidua and chorion; this however is merely a combination of cases already noticed.

6. In the substance of the placenta. This, our author remarks, is a very frequent accident in the early stages of pregnancy; it happens however occasionally at more advanced periods, as in the following:

Case.—Madame F——, aged 32 or 33 of a lymphatic and nervous temperament, was subjected to a severe fright at the end of the ninth month of pregnancy. The movements of the child, which had previously been very active, immediately ceased. This took place on the 3rd May, at 8 p. m. During the 4th and 5th, she experienced an unpleasant sensation of weight and *déplacements de totalité* whenever she changed her position—we leave the reader to interpret this phrase for himself; it appears to us rather too vague for scientific language. In the night of the 5th, slight fever supervened; the breasts swelled, and at the end of 24 hours contained a great quantity of milk. From the seventh to the twelfth nothing remarkable happened; the patient only complained from time to time of pains in the region of the kidneys. On the night of the 13th, the pains grew more frequent and severe; they soon became expulsive, and delivery took place at five in the morning, without any hæmorrhage. The child was dead, and the epidermis was easily to be detached. The placenta was naturally expelled; it was covered in a third of its extent by a mass of black and very firmly coagulated blood. The umbilical cord, towards its insertion into the placenta, was ecchymosed in an extent of three inches; the blood that formed this ecchymosis appeared to come from the principal clot, which occupied not only the centre of the uterine surface of the placenta, but also several of the intervals between its lobules. (*Journ. Gén., t. 68, p. 339*).

7. Between the umbilical vessels and the

membranes surrounding them; in which case the blood may be either in a single clot or infiltrated.

Case.—A woman was naturally delivered, at the full time, of a dead child, around whose neck the cord, fifty-two inches in length, was six times twisted. At the distance of a foot from the umbilicus a coagulum of blood eight or ten lines long was found between the membranes and the vessels of the cord; it had been effused from a rupture in the umbilical vein, which was varicose in several places. (*Deneux, Journ. Gén., t. 63, p. 361*).

This case exemplifies a singular cause of the death of the child. M. Baudelocque believes it to be unique; he observes, however, that De Lamotte, Levret, and Baudelocque (senior), have recorded instances of effusion into the cavity of the amnios, in which the blood proceeded from the umbilical vessels.

7. The cavity of the amnios.

A case is related by M. Coutèle, in which pregnancy was mistaken for *ascites*, and paracentesis was performed! (*Constitution Med. de la ville, d'Albi, part 2*). We presume the operator was a *pure*; midwifery is beneath a surgeon. This, however, ought not to have been introduced among natural cases of internal hæmorrhage: if all the accidents caused by the blunders of anti-obstetrical surgeons were recorded, we should have a queer pathology.

8. In the cavity of the peritoneum, which may occur at any period of gestation.

Case.—A woman in whom the menses had not appeared for six weeks, had a fall upon her knees, some hours after which colic pains came on, and continued with violence for twenty hours, when the menses returned, and the pains were somewhat abated. M. Littre, who was called in on the third day, found the patient pale and covered with cold clammy perspiration. The abdomen was distended, the breathing laborious, and the pulse small and intermittent. The patient complained particularly of constriction of the chest, and of acute pains in the left iliac region. Death soon occurred. A foetus, about an inch long, was found in the abdomen, and more than four pints of blood,

which had been effused from a laceration in the left fallopian tube. (Mem. de l'Académie des Sciences, an. 1701).

II. During the process of parturition, blood may be extravasated.

1. Between the uterus and the external surface of the placenta and membranes.

Albinus relates a fatal case in which the effused blood formed a cavity for itself by detaching the central portion of the placenta, while the margin retained its adhesion as in the instance just alluded to, which occurred to M. Delaforterie. "Had the nature of the case been understood," observes Albinus, "the patient might have been saved by rupturing the membranes and delivering immediately." (Annot. Acad., Lib. i, c. 10, p. 98).

2. In the substance of the uterus and cavity of the abdomen.

An example is acted upon from Schmucker's *Mélanges des Chirurgie*, which M. Baudelocque observes stands alone in the history of the science.

A woman became pregnant six months after a Cæsarian operation, from which she had perfectly recovered. She was brought to bed at the full time, almost without pain, of a dead child; six hours after, she fell into a state of syncope, and died. On dissection, a mass of coagulated blood was found under the peritoneal coat of the uterus, and distending this membrane into a sac, whose parietes were traversed by varicose vessels opening on its internal surface. There was a hole in the sac, through which the blood had escaped into the abdomen. The cicatrix resulting from the Cæsarian operation she had undergone was firm and uninjured.

3. In the cavity of the amnios; cases of which are recorded by Levret and Baudelocque, senior, but the source of the hæmorrhage in these instances has been disputed by others; we therefore omit them.

(To be continued.)

The London Medical

AND

Surgical Journal.

Saturday, March 7th, 1835.

THE LIVERPOOL MEDICAL INSTITUTION.

Hæc ego non credam Venusinâ digna incernâ?

Hæc ego non agitem?

Juvenal, Sat. 1, 51.

We happen to have some acquaintance with the state of medical tactics at Liverpool. We are aware that the whole profession is looked down upon by the purse-proud merchants of that town; that, like tradesmen, the very physicians are required to send bills for attendance, and that other indignities are inflicted, unworthy both the patient and his professional man. One portion of the profession yield to this systematic insolence, take the crumbs that are thrown at them, and bless God that they have such bitter food. Another portion, though the chances of practice may thereby go against them, make that stand on their professional dignity, from which, were they well seconded, better fees and greater weight in the social body would accrue to them.

The characteristics of these two sections of the Liverpool faculty have been tolerably well developed in the late meeting, held there for the purpose of erecting a building for *their own* social and scientific purposes—a report of which is given in our last number. The faculty of the town petitioned the committee of the Royal Institution for a grant of land adjoining the latter, on which to erect the proposed building. The committee agree to make the grant, *provided* the building so erected shall be by legal deed invested in them, the property therein contained inalienable (that is, not removeable from the edifice), and themselves and those whom they think proper to introduce, free at all times to enter the premises. These provisos, our readers will agree with us

in considering "most tolerable and not to be endured." Not so, however, certain persons who figured at the meeting in question. One long-suffering son of earth, a lamb that would

"Lick the hand upraised to slay,"

meekly tells the company that "*all that the proprietors of the Royal Institution seemed to claim was simply that they, and none else, should be the owners and trustees of the property, legally considered. Had they even,*" pursues the speaker, "claimed, in the same spirit and sense, a right to the property of the medical library" (we may mention to our readers that this library has been many years in existence in another locality) "there could be no objection (!) but one of *mere feeling, even to that.*" Exactly, my friend; it is the *feeling* we insist upon: the Royal Institution committee may assuredly be trusted with their own property; they appear to be sharp lads, and to be acquainted with

..... "the plain and simple plan,
That they should get who have the power,
And those should keep who can."

If the medical men of Liverpool can gulp this grovelling and stolid argument for prostrating themselves in the dust, they deserve all the spurning which the ignorance or the insolence of the committee may please to confer upon them. And if the majority of them can sink the *feeling* of self-respect, and substitute that of dependance and degradation, give up the library they now possess, and the museum they intend to form, for the paltry gift of a piece of land, value 240*l.*, they prove themselves egregiously bad financiers, and grievously narrow-minded members of a liberal profession.

Another orator—a Fellow of the Pall Mall College, a Cantab., and one therefore who is supposed, or supposes himself to have had the exclusive advantage of a previous general literary education, comprising, we presume, a

classical acquaintance with his mother *English*—took the same time-serving view, and expressed himself in the following beautifully eloquent terms:

"Mr. Chairman, I have really very little to say *at all*; and as I have been so short *a while* in the room, perhaps I ought to say nothing *at all*. But since I am upon my legs, I will observe, that *if* the profession *can carry* this work on by themselves, let them do so—*provided they can*. If they cannot, *which* is my opinion, then it will be as well that they connect themselves with the Royal Institution; for, unless so connected, the public at large will not support them in their undertaking."

The remainder, that is, the majority of the speakers, however, we are happy to see, maintained the contrary propositions to those above quoted. Among these we rejoice, though we are not at all surprised, to observe the honoured name of Carson. He took the lead in the development of the objections to the grasping policy of the Royal Institution committee; and was followed by Dr. Jeffreys, who proposed the formation of a committee to confer with that of the Royal Institution—a motion that was eventually carried.

Our readers may ask wherefore the *exigeant* proposal of the Royal Institution came to be entertained at all, and to find supporters among men of supposed education and high-toned feeling. The question is answered by the fact that the shareholders of the Royal Institution are composed of the greater number of the influential merchants and bankers of Liverpool—a fact, we have every reason to *suspect*, known to those who supported the proposals of the shareholders.

Meantime, we hope and believe that the Liverpool faculty will assert their own dignity by holding no longer conference on proposals so fraught with illiberality and the spirit of extortion. Should such be entertained and carried, the degradation of the profession will

be perpetuated. Do they meet in their building for the discussion of any subject which happens to be disagreeable to any Royal Institution shareholder, the latter has only to introduce a given number of friends, and mar the proceedings. Should they, for instance, meet to discuss the best mode of associating for the purpose of obtaining better remuneration for their attendance—a desideratum, we can assure our readers, in Liverpool practice—the introduction of a mischievous or malignant set of persons to render the intention abortive, would meet with no obstacle. Let the Liverpool faculty exert their ingenuity in supposing cases in which the powers granted to the Royal Institution might work to their annoyance and disadvantage: they will find such in abundance. Let them be certain that the straightforward path of proper self-respect is in the main most conducive to their welfare in practice, and their influence in the community. To medical men who think otherwise, to practitioners of vulgar minds and cringing habits, we would recommend the advice of the Gallic Horace, contained in the following lines:

“Soyez plutôt maçon, si c'est votre talent,
Ouvrier estimé dans un art nécessaire,
Que *medecin* commun, et *docteur* vulgaire.”

—o—

THE RHABBARBARIANS.

IN our last number we gave these worthies a slight switching with the tail of our leading article. We prophesied their evaporation into thin air: the following remarks may be given as the *rationale* of that interesting process.

There is one consequence of medical reform to which we look with peculiar pleasure; we allude to the curtailment of the powers held by the non-descript Company of Union Street, Blackfriars. That this will follow upon any *real* reform of the College of Physicians there can be no doubt. For, granting

that the cant about the “average improvement of the general practitioners” be taken as an argument for the continuance of their ill-gotten charter, and their impudent intrusion into the ranks of the profession, yet of what avail will these be if the cleansing of the College of Physicians be effected—if that *once* honoured precinct again become a locality where all may register their names who come with the recommendations of talent and education. Suppose the ingress to that College facilitated as to the qualifications of local habitation and name, though rendered more difficult and therefore more honourable as to the mental qualifications of the candidate, can it be for a moment doubted that each and all will prefer to style themselves members of such a body, rather than come forth as the licensed dispensers of a hybrid trading company? Add to this, if the tight laced etiquette of the present system of medical fees be abrogated—if it be pointed at as no social degradation to accept a smaller fee than the certainly enormous one of a guinea—we see no possible salvation for this piebald society of medico-druggists. Reform of *them* would, in such event, be a work of supererogation—it would but strike a falling body—they would die of sheer inanition, of a dearth of candidates, of a famine of diploma-fees. Revolving Thursdays would present themselves, but not “big with the fates” of a dozen trembling candidates, as in past and present halcyon days. In vain would the fresh botanical specimen be plucked; in vain would the dusty herbarium be produced, the often exposed coloured plates be “laid on the table,” the well worn pharmaceutical preparations be placed in order in their bottles and compartments, to dismay and puzzle the expected examinee! To no purpose would the clerk fill up the blank diplomas, the spruce beadle be in waiting to usher the joyous licentiate to the presence of the now no longer formidable

coterie, seated round their half-moon table! Instead of the condescending approval addressed to the successful, or the rough, ill-bred rebuke to the dejected rejected one, these lords of the pestle and mortar will be seen wandering about their hall, like the discontented ghosts in Virgil's hell, and will be heard only to utter the acknowledgment of their past greatness in the suspiratory syllables "fuimus! fuimus!"

And who shall mourn over them? Not the Fellows who, after years of "cawing" with, after years of successful play into, the hands of these tradesmen whom they ever scorned; now that power has knocked at their own doors, and given the word of command—"Reform"—they will gladly throw their old allies overboard, and come into measures whose effect upon the Apothecaries' Society we have already predicted. Not the surgeons, between whom and the people of Union Street, it is well known no love was ever lost; in the sight of the latter, the College of Surgeons was ever what the Arab is to the sight of the Catholic Musselman—an object of hatred. Not the licentiates of their own body; for which of them cares a straw for the physicians about the hall, after he has paid his diploma-fee? Nor can the public regret what must be an improved change for them, in the eventual substitution of real professional men for persons authorized to charge for the amount of physic they *choose* to send, and not for the quantum of skill they *are able* to exhibit. On all hands we shall hear gratulations rather than condolence, and the only wonder, the only drawback to the felicitations on the event, will be that a body so devoid of the requisites of settled dignity and fixed character, should have lorded it insolently over the whole profession during twenty long years!

—o—

STATISTICS OF THE PARISIAN HOSPITALS.

From official returns lodged at the bureau of the Prefect of the Seine, it appears that the receipts of the Parisian Hospitals, for the year 1833, amounted to 10,186,388 francs, (nearly £408,000), the whole of which appears to have been expended. The principal receipts are from rents (*loyers fermages*), 1,136,271 francs: government grants (*rentes sur l'état*), 4,201,472 francs: from the city of Paris, 5,238,000 francs. The lowest item of receipt is individual aid (*rentes sur les particuliers*), 11,000 francs: the income from the Monte-de-Piété or licensed pawn-shops, 281,970 francs: from the theatres they draw 60,000 francs: they also draw 400,000 from the departments, for the support of the maternity section of the hospitals, it being presumed that the little foundlings are not all of Parisian parents.

Of the expenses, the chief head is that for food and treatment of the poor, (for be it remembered, that many patients in the French hospitals pay for their maintenance and medical treatment, the item of receipts for this being 386,100 francs), amounting to 3,627,906 francs: then comes out-of-door assistance, 1,516,025 francs: foundlings and orphans, 1,450,000: materiel, bed-clothes, &c., 1,381,478 francs, and expenses of management, 1,135,442 francs.

The localities for relief are of three kinds. First, the hospital establishments, 24 in number: of these 13 are hospitals or establishments for the sick, and contain 5,337 beds; and 11 are infirmaries (*hospices*) for the old and infirm, as also for orphans, in which 11,740 persons may be maintained. The total of the beds of these hospitals and infirmaries is 17,077. The second kind of relief is afforded at certain asylums and schools: the number relieved by this means in 1833, was 68,986.

The third class includes the foundlings.

On the 1st of January, 1833, the number in the hospitals was 4,170, and there entered during the year, 61,765. At the same date there were 9,547 in the infirmaries, and during the year, 3,190 entered them. The number of foundlings and orphans, on the 1st of

January, in their respective places of charity, was 17,433, and during the year, 5,693 deserted children, and 1,760, passed from the *Bureau des Nourrices*, were received. Add to the above the 68,986 relieved out of doors, and we have a total of 172,564 succoured by the funds of the Parisian hospitals.

With regard to the individual expenses of the patients, the number of days included in the treatment of the patients in the hospitals was 1,616,403, for which the expense was 2,609,249 francs: taking the average, therefore, the expense of each day is 1 franc, 63 centimes, 51 milliemes. The average period of sojourn of each patient being 23 days, each one was maintained at an expense of 38f. 20c. The number of deaths was 5,886 or 1 in 11 1-80ths. In the infirmaries the deaths were 1 in 6.08: in them also the average expense of the day was 90c. 42m. The cost of each foundling was 74f. 43c. per annum.

The expenses of out-door attendance was 2,288,177; dividing this sum by the 68,986 so relieved, the average for each will be 33 francs, and dividing it by the number of households (*menages*), which are 31,723, we have 72f. 13c. for each. In these households there were reckoned 16,167 men, 28,021 women, 12,096 boys, and 12,702 girls. The heads of these households were 13,173 married, 12,875 widows, 4,350 unmarried, and 1,325 deserted females.

From all these calculations, the indigent population would be to the whole population of Paris, (estimated at 770,286 in 1833), as one to eleven.

These statistics no one can deny are useful in a national as well as medical point of view. Moreover, they evidence to the public the strict manner in which the funds for the support of the hospitals are appropriated to the uses—and only to the uses—for which they were intended. But with us—!

Hospital Reports.

NORTH LONDON HOSPITAL.

Spontaneous Gangrene.

SARAH ARNOLD, aged 75, was admitted into ward No. 1 of this hospital on the 26th of January of the present year, under the care of Mr. Liston. She has been much exposed to cold and wet, from following her usual occupation, which is that of a water-cress seller. About

six weeks ago, after having been exposed as usual, she was seized with rigors; two or three days after this she began to complain of slight pain, with clenching of the fingers; they at the same time became discoloured at the tips, and sensation in them became much impaired. No remedies were then employed; the discoloration continued to extend, and about a week after its commencement had passed the wrist; the hand had become dry and shrivelled, and motion and sensation were completely lost in it.

A medical man was now called in, who made use of some local application to the arm, and gave some medicine internally, but without any good effect; and in about a fortnight from her first seizure, the disease had reached a little way above the middle of the arm—there it stopped.

At present there is a well-marked line of separation between the living and gangrenous parts; and suppuration has commenced on the inner side of the arm, at which part the disease has extended a little higher up than on the other. There is slight pain, and that is chiefly referred to the living parts in contact with the diseased. The powers of sensation and motion are completely lost in the affected parts, and the whole hand is dry and shrivelled, but she complains of a disagreeable, trifling pain in the fingers. Above the wrist, the arm is soft and flaccid, the pulse cannot either be felt at the extremity, or at the axilla.

She complains much of debility, but her system seems to be but little affected. Her appetite is good; the skin is moderately warm; pulse in the other arm 70, and of good strength; tongue moist and clean; sleeps little.

Haust. cum solutio. mur. morphinæ.

M. xxv. h. s. s.

Sumat. vini rubri. ʒ iv.

Water dressings to the arm at the line of separation.

27th.—Continues much the same as yesterday; heat of skin natural; complains of pain in fingers of the diseased arm; intellects clear; no expression of anxiety in countenance.

Haust. anody. rept.

Cont. vinum. Full diet.

28th.—Suppuration on the inner side of the arm, copious and foetid; the livid spots on the outer side of the arm have not extended; but there is some very slight redness around them; pulse about 100, of moderate strength; tongue clear; heat of skin still natural, and appetite good; bowels moved once since last report.

Cont. vinum et haust. anodyn.

A little chloride of soda to be added to the dressing.

29. Suppuration much the same as before in quantity, but more foetid. The separation

between the dead and living parts, which had taken place slightly on the inner side of the arm when she was admitted, is extending a little, both on the inner and outer side of the arm. Pulse 98, of moderate strength, skin natural, tongue clean and moist. Bowels open, appetite excellent.

Con. medicamenta.

30th.—Much the same as yesterday—sleeps a little better.

31st.—Suppuration more copious and still extremely foetid; separation between the parts progressively on the inner part of the arm, but no change in the appearance of the livid spots on the outer side. Pulse 102, still of very good strength. Bowels regular, appetite good. Tongue clean and moist.

Cont. vin. et haust.

Feb. 2nd.—The separation of parts on the inner side of the arm advanced a little; the livid spots on the outer side have disappeared, except the largest, where a small superficial slough seems to be forming. The diseased parts were removed to day, the line of separation having fairly formed, and suppuration taken place in a great part of its extent. The soft parts were divided by means of a pair of scissors, cutting as near to the living parts as could be done with safety. The bone was then divided as high up as possible, a bistoury having been previously passed round it, so as to insure the division of the soft parts, and only a slight oozing from the bone, which was found to be alive when it was divided.

Cont. vinum et haust.

Water dressing to the stump.

3rd.—Continues much the same as yesterday. Pulse 104, of good strength. Tongue clean and moist. Bowels moved once. Skin natural—appetite good.

Cont. med. et vin.

5th.—Suppuration copious; a portion of the dead parts left have separated, and a healthy, florid, granulating surface remained.

8th.—The greater part of the slough have separated; the stump presents a healthy granulating surface.

Perstat.

9th.—Stump looks well, as the posterior part of the end of the bone where it was divided is covered by healthy granulations.

March 4th.—Gradually improving since the last report. She is now so strong as to be able to walk alone in the ward—no sign of disease in any other part of the body.

The arm was examined after its removal. The arteries and veins were found perfectly healthy, the latter without any coagula in them.

—o—

MEDICAL FEES.

To the Editor of the Original London Medical and Surgical Journal.

SIR—In the leading article of your excellent Journal of the 21st instant, I observed an able notice of the present state of the

profession in regard to Physicians' fees. This is a matter in which non-medical people are as much concerned as the profession itself. It has fallen to my lot to feel the effects of the system, and as I have conferred with other heads of families, I have found a remarkable union of sentiment on the subject.

It has occurred to me, when I could ill-afford to give a guinea, or even half a guinea, for each visit of a physician, to defer the application for his aid till it was too late; and how many commit the same fault is too generally known. But when the physician chides the sorrowing relation for the apparent neglect, he is not apt to discover the cause, in the mode of remuneration established by the conventional rule of his class. He forgets that there are thousands who, with a general ability to pay at this or that period of the year, cannot at the moment of calamity raise the means of defraying the exorbitant charge as well as all the other increased expenses, which a sickness occasions. How great they are too frequently, when the individual who is sick is perhaps the head of the family, upon whose labour they depend for subsistence, and the suspension of whose exertions creates a double want; or the mistress of the family, whose economy is as necessary for the management of the limited income, as the energies of the husband are in another direction. We must not wonder that in such a case the physician, who comes now too often as the herald of death, and whose presence therefore all are too desirous to put off, is subject to the further cause of postponement, which is found in the deduction which his fees will make in already scanty resources. It is this which makes the physician a fashionable luxury, which small people must not indulge in, until the last extremity.

I do not suppose that the physician should go without his fair and full recompence; but I think it would be much better that he should receive it in a different manner. There should be no direct connexion between his gain and his patient's calamity—no seeming interest in the perpetration of an evil, which, though it destroy not the patient, is yet deeply wounding him in his fortunes.

The physician should be remunerated by an annual or quarterly stipend, estimated according to the means of his patient and the number of his family; and his attendance should be on the footing of a friend interested to prevent illness, rather than to increase it. I do not say that his salary should be suspended if his patient became sick; on the contrary, I think it should be increased by a gift or honorarium proportioned to the difficulty or danger of the case; and if the patient should be so insensible to what was due to his skilful friend, he might, on the arrangement for the ensuing year, stipulate for a higher stipend,

estimated on the increase of business during the last.

Severe diseases would be comparatively rare—they would be taken in time. The physician would learn accurately the nature of his patient's constitution; the latter would freely state his ailments before they became confirmed maladies; and, what is of still more importance in melancholy temperaments, they would be taught to distinguish between the indispositions that arise from the changes in the atmosphere and those which result from a diseased state of the body. Men engaged in active studies, who must work, well or ill, who require to possess their faculties in the clearest state, and like horse-racers, or prize-fighters, always to be in good condition, might be assisted to that object by the judicious and timely care of their medical advisers. Again, prescribing would cease to be a grave quackish performance, in which a man holds a pulse for a few moments, looks from the face of his patient to the ceiling or on to the ground, and then to his patient's face again; and, after a few seconds' consideration, and a few unimportant questions, affects to know the whole extent of a disease that may be constitutional, and the growth of years. The intercourse which the medical man had had with the patient in health, as well as in sickness, would have taught him the general cast and expression of his countenance, his manner, his conversation, and what sort of temperament belonged to him. He would make his physiological observations on a healthy subject as well as on a sick one, and, comparing his diseased with his healthy state, be able at a glance to discover the extent of deviation from the ordinary standard of his health. He would naturally, too, know something of his patient's pursuits, and their probable effect on his general health. In short, Sir, the field of a physician's experience would be enlarged; he would not be the hated or the feared grave man in black, nor liable to imputations of indelicacy for a persevering discharge of his duty, because his patient was impatient of restraint, or eager to get rid of the drain upon his resources. The general mode of paying by a fixed payment according to means, would enable the poor man to retain the services of a physician, who would be fully recompensed by his general return from the rest of the patients. A man of science, devoted to his profession, and eager to do good, rather than to pursue a mere trade of practice, leaping from room to room, giving a moment's thought to the patient, and two to his fee, would, in the attendance of a limited number of families, derive a full means of subsistence, with an ample opportunity of prosecuting his pro-

fession, in a pains-taking inquiring spirit, and not in the harem-scarem bustle of a practice exceeding the powers of man to do justice to it. Such a man would not be a bear—but returning to the ancient courtesies for which the physician was once remarkable, without the fopperies, though of a different sort, that then, as now, made him ridiculous, would good-humouredly enter into social intercourse with his select circle of friendly patients.

I fear, Sir, I have been painting a millennium—but I am convinced that much of social and personal evil results from the present practice, and that the physician is degraded by it as much as the public is injured; and therefore I speak thus earnestly.

I am, Sir,

Your faithful Servant,

PATERFAMILIAS.

[We shall make a few remarks on the letter of our correspondent next week.]

LECTURES

ON

MEDICAL JURISPRUDENCE,

DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,

At the University of London; Session 1834-35.

LECTURE XXI.

GENTLEMEN—Having made you aware of those diseased states of the habit which closely resemble insanity, but are not that disease, it is now proper that I should put you in possession of the knowledge of those symptoms for which you must look, in order to enable you to pronounce any person to be in a state of unsound mind. But, before doing so, I must state broadly my opinion, that medical practitioners, in setting aside the vague ideas of diseased mind, and observing closely the influences of physical causes on the mental powers, have fallen into the error of ascribing too much to the state of the body in mental disorders.

One of the first inquiries in a case of mental alienation, whatever character it may assume, is into the history of the family of the person supposed to be insane; and in particular, whether any hereditary taint exists in it. It has been seriously doubted whether insanity be hereditary: but the most correct observation and experience have verified the hereditary character of the disease: it is a poison which has unfortunately mingled with the stream of population in this country, and it is impossible to anticipate the extent to which it may flow. The difficulty of determining this point, however, is very great; the disease may remain latent through one generation, and appear in the next with augmented force; the hereditary character, however, refers rather to the tendency or predisposition to the disease, than to the malady itself; a greater susceptibility to those impressions which are likely to rouse it into action. This state, however, may exist to a great degree, and yet insanity may not appear, particularly if the regimen, the moral habits, and the pursuits of the individual be such as are unfavourable to the

excitement necessary for awakening the malady, the seeds of which, as it were, lie concealed in his constitution. When, however, the reverse of this happens, and circumstances occur to operate as exciting causes upon a habit predisposed to insanity, the eccentricities which indicate the approach of the disease, and upon which you may be sometimes called to decide, will lead you to give a more cautious diagnosis than you would otherwise hazard, if you were not aware of the hereditary taint in the family of the individual. Let us take an example—A patient feels occasional pain or sense of fulness in his head, he becomes incapable of confining his attention, neglects his accustomed employments, is sleepless, loquacious, and, contrary to his usual habits, decides positively upon every subject that is started; is impatient of contradiction, and scorns reproof: if at the same time he supposes that offences are offered to him, and injuries inflicted, and plots contrived against him, which were never thought of by any other person; if he seem confused and wandering in his manner, like a half-intoxicated man, and speak with eagerness and impatience, as if the ideas were not only too rapid for his utterance, but had crowded into his mind in a state of confusion: under such circumstances the approach of insanity may be strongly suspected. Still, in such a case you may justly hesitate in pronouncing an opinion; but this hesitation will be greatly lessened, if you are made aware that any of the branches of his family have been insane. In such a state also, we must carefully inquire into any change in the habits of the person; whether he have lately indulged more freely in the use of wine; if, from having been abstemious, he now drinks freely; if, from being reserved and modest, he talks boldly—is not backward in entering into society from which he refrained—acts obscenely—and tempers his wit and vivacity with unusual oaths; displays violent gusts of passion: upon such evidence we can have little doubt of, at least, the near approach of insanity. It is seldom, however, that a physician is required to deliver an opinion in this stage of the disease: I say the dis

ease—for the malady, although not very obvious to ordinary observers, already exists. It is true that the extravagancies of eccentricity may be so great, that it is extremely difficult to discriminate between them and insanity; and the family of the insane person is always disposed to regard the precursory symptoms of insanity rather as eccentricities, as sallies of humour, than what they really are; thence the disease is permitted to advance to its perfect and fully formed state, and health, fortune, and character, be all on the brink of ruin, before any medical opinion be required, or any proper care be taken of the madman. It is at this period, then, that you are most likely to be required to authorize confinement and restraint, or to confirm the truth of the allegation of insanity, when it becomes an object of medico-legal inquiry.

The approaches of insanity, however, are not always so progressive as the description which I have given you would lead you to presume; the patient is sometimes seized in a moment; the disease assumes at once its true character, and crimes are perpetrated, under such circumstances, which baffle both the discriminating judgment of the physician, and the decision of a court. The state which is most likely to be mistaken for this sudden accession of disease is anger, under the influence of which crimes are often perpetrated, which receive pardon, from the conviction that the plea of insanity which is set up is well founded; it therefore behoves you to be able to point out the distinction between ungovernable anger and the delirium of a sudden accession of mania. Anger is not confined to man; the instinctive feeling of self-preservation, which probably is the origin of the passion, is felt even by the insect, who returns injury for injury; and, in the human species, equally by the weak and the strong, the child and the man, the peasant and the philosopher. There is generally some real injury, or some supposed injury, before anger is roused; a state of suffering is inflicted, either bodily or mental, which awakens in the person feelings of the most lively kind, to remove it: and to effect this the passion is roused, to make the offending person feel the power of the sufferer, and to know that the vengeance is equivalent to the injury. The degree of anger which is thus roused, is regulated greatly by the temperament of the individual; in some persons the slightest causes raise great turbulence of spirits and ebullitions of blood; in others these states are not produced by the greatest injuries; in some the passion is overpowering, and terminates like the tornado; in others it continues after the agitating cause has ceased, gradually subsiding like the swelling billows, after the storm has spent its fury. Let us examine physiologically the effects of this passion on the individual, so as to be able to compare it with those of the delirium of insanity.

There are two distinct states of anger, which are known by the terms, *burning anger* and *pale rage*.

In the first the heart and arteries are excited to inordinate action, the blood is propelled with violence to the surface of the body—thence the sensation of burning heat which is experienced; the face becomes flushed, the eyes sparkle, the breathing is convulsed and irregular, and as the muscles contract, as it were with clonic action, the blood cannot return readily to the heart, and consequently the veins of the face and neck swell, grow tumid, and seem ready to burst; the teeth are firmly set, from the spasmodic contraction of the masseter muscles, and the whole physiognomy assumes that aspect which fully justifies the adage, "*Ira furor brevis est*:"—yet this state is not insanity.

In pale rage the reverse of this state occurs; a deadly, pale, and livid hue overspreads the face, the features shrink, the skin is corrugated, the eye-brows are knit, the eye has a dull rather than a fierce character, the blood is congested upon the interior, and the passion seems stifling itself; or, as Burns quaintly describes it in the person of a sullen dame—

"Gathering her brows like gathering storm,
Nursing her wrath to keep it warm."

Now, in either of these states, although the terror of public shame and punishment be thrown out of view in the excess of the passion, yet it immediately occurs after the crime which results is perpetrated; the sudden and associated thought of personal danger calms the fever; but this is not the case in the criminal who has been impelled to the deed of blood by the sudden accession of insanity; and this affords one point of comparison in forming a diagnosis, independent of those corporeal signs which I will point out, in describing the paroxysms of mania. In the angry man, the recollection of the crime produces serious and deep reflections: in the madman, when the delirium subsides, instead of being reflective, he becomes gay and social, he remains unaffected by the act, ungoverned by reasonable conclusions. A powerful man, who had been subject to epileptic attacks, when these subsided, became suddenly furious, and during the transports of his disorder, murdered two children and a woman. For this act there appeared to be no motive. He was confined in a lunatic asylum, and remained tranquil and did not discourse irrationally, and when questioned regarding the murder, replied that he knew nothing of it—that some person had informed him of his crime, but he had no more memory respecting it, than if it had been committed in his sleep.

I must not be misunderstood in using the term sudden accession of insanity. It sometimes occurs suddenly, without any obvious exciting cause; but in these instances there is generally a predisposition

to the disease—some hereditary taint: more commonly, however, before such furious paroxysms occur as to resemble a sudden ebullition of violent anger, many symptoms are obvious, which indicate the approach of the disease; but they are too frequently either overlooked, or the relations of the patient oppose themselves to those measures which, if timely adopted, would generally prevent the evils which are vainly lamented, when it is too late to avert them.

An excellent illustration of this remark is quoted by Sir Alexander Crichton, in his *Inquiry into Mental Derangement*, from the third volume of the *Psychological Magazine*. (Here the lecturer read the extract—see vol. ii. p. 59).

In this case the self-conceit, contempt for the prevailing opinions of the world, pride, and irascibility of the lunatic, were sufficient indications of approaching insanity; and it would be fortunate for the welfare of society, were the limits between real religion, and that fanaticism which leads to absolute frenzy, more distinctly and generally perceived.

Let us now suppose that the disease actually exists; and that your evidence is called for to determine the point—What are the proofs which should lead you to pronounce the presence of actual derangement? To enable you to pronounce in either way, the disease, in the first place, must be thoroughly understood. The physician ought not to come into court, should this be necessary, merely to state opinions, but be fully prepared to support those which he advances, and to give the reasons which have influenced his decision. He must also be prepared “to submit his opinion to the comprehension of the ordinary persons who are to appreciate his deposition.” In delivering his opinion, that the irregularity of the actions of the supposed lunatic can be accounted for only by admitting the deranged state of his mind, the physician must also be prepared to prove that the state of insanity is sufficient to account for these; and that, in a sound mind, the impulses by which he is goaded for the accomplishment of his purposes, although they cannot be traced and explained, yet would not have operated in the same degree. To perform this duty in a satisfactory manner, the medical man must look at the prominent and most characteristic features of the disease, both as these increase his own acquaintance with it, and enable him more easily to convince others that he possesses such an intimate knowledge as alone can give weight and importance to his opinions regarding it. You must also always bear in recollection, that in the eye of the law, two witnesses deposing *sanæ menti*, are preferred and believed before a hundred, touching fury and madness: thence the necessity of being able to put forward the most prominent points which establish the fact of

the existence of the disease. What are these points?

In the first place, the practitioner must distinguish the variety of forms in which the disease shows itself, whether as *Mania*, *Melancholia*, *Dementia*, or *Idiotism*: the first only, strictly speaking, are madness; the third is mental alienation from functional disease of the brain; and, in common with the two former, deprives the unfortunate object of it of the control of his person and property: the fourth, although usually classed with insanity, is evidently a distinct species—not a derangement of mind, but the deficiency of intellectual power, congenital, not acquired. The legal division is somewhat different, as the following quotation from Littleton will explain.—“*Non compos mentis*,” says Littleton, “is of four sorts: 1. *Ideota*, which from his nativité, by a perpetual infirmity, is *non compos mentis*: 2. Hee that by sickness, griefe, or other accident, wholly loseth his memory and understanding: 3. A lunatique that hath sometime his understanding and sometime not, *aliquando gaudet lucidis intervallis*; and therefore he is called *non compos mentis*, so long as he hath not understanding. Lastly, Hee that by his own vitious acts for a time depriveth himself of his memory and understanding, as he that is drunken.”

Mania, considered in a medico-legal point of view, “annuls a man’s dominion over property; dissolves his contracts and other acts, which in his sane state would be binding; and takes away his responsibility for crimes:” in a medical point of view, it may be described as “a state of mental alienation, accompanied by turbulence and unusual ferocity in language and deportment, and by a comparative insensibility to ordinary stimulants.” From this description it is evident that the most striking features by which actual mania is to be recognized, are displayed in the physiognomy of the affected person, the condition of his nervous system, and the perverted state of his ideas. The physiognomy of mania consists chiefly in a peculiar cast of countenance, which is familiar to those conversant with the malady, but not easily described; it is something which seems to involve gloom, suspicion, and ferocity. There is a wildness in the eye, which is protruded and glistening: it has a wandering motion in every direction, in a manner peculiarly disagreeable to a beholder. Sometimes, however, it is sunken and dull, fixed upon some object for hours together, or bent on vacuity; or, it seems to follow some phantom which is evidently present to it. During a paroxysm of high delirium, the eyes appear as if firmly pushed forward, and the iris is contracted. With this state of the pupil, we often find a condition of the scalp, which although it be not strictly physiognomical may be mentioned here. It is “a relaxation of the integuments of the cranium,

by which," says Dr. Haslam, who first noticed it, "they may be wrinkled, or rather gathered up by the hand to a considerable degree." The gait of the maniac is quick and hurried, yet, frequently, he stops suddenly and turns round, but not as if to regard any thing, but more in the manner of an absent man. The prevailing complexion of maniacs is swarthy; and, when not naturally so, it soon acquires this hue. Out of 265 maniacs who were examined, "250," says Dr. Haslam, "were of a swarthy complexion, with dark or black hair: the remaining sixty were of a fair skin, and light, brown, or red haired. Along with these physiognomical characters, although the look is often fierce, and they are boisterous, yet they are frequently almost instantly subdued by the fixed gaze of a decided person; for pusillanimity is a remarkable trait in the character of the insane." During the paroxysm, the action of the body is violent and vigorous, with great exertion of muscular strength; they remain awake for many days and nights together, talking incessantly, sometimes in the most boisterous manner; then suddenly lowering the tone, speak softly, and in a whisper, varying the subjects, and passing in the most incoherent manner from one subject to another, totally unconnected with it. This watchfulness, nevertheless, does not produce a dull and sunken state of the eye, as in cases of sanity, worn out by watching: but it remains sparkling and protruded. There is, finally, a systematic dignity in mania, which never can be imitated by the most expert mimic, and is peculiar to this disease.

The second description of the obvious characteristics of mania depends on a change produced on the nervous system. Owing to this, there is frequently a great indifference to food, and the want of it can be sustained, for a very long time, without any apparent inconvenience. At other times the appetite is voracious, and every thing is swallowed which comes within the reach of the lunatic. From the same state of the nervous system, maniacs are able to endure greater degrees of heat and cold, and more sudden alterations of temperature, with impunity, than sane people; this does not, however, secure them from the usual effects of severe cold; indeed, they are very liable to mortification of the toes in winter; but, at the same time, they suffer less pain than sane persons in the same state. There is, also, a general insensibility to external impressions; probably, in part, attributable to the great mental excitement absorbing, as it were, the whole of the attention; and it is not unlikely that the deficiency of memory, which is so remarkable in maniacs, arises from the same cause. This is indeed one of the most striking features of the disease, and is beautifully alluded to by our immortal dramatist, whose keen observation no state of human nature, whether

diseased or healthy, escaped. Hamlet, in his interview with his mother, is accused of madness, when he desires her to look at the ghost, visible only to him: the Queen says,

"This is the very coinage of your brain :
This bodiless creation, ecstasy
Is very cunning in,
Ham. ———— What ecstasy ?
My pulse, as yours, doth temperately keep time,
And makes as healthful music. 'Tis not madness
That I have uttered: bring me to the test,
And I the matter will re-word; which madness
Would gambol from."

Besides this altered state of sensibility, here is an evident perversion of sensation.

This accounts for the *tinnitus aurium*, and the delusions connected with the organ of hearing, which are such constant accompaniments of mania. The conversations which the celebrated Tasso held with his familiar spirit, can be accounted for on this perverted state of the faculty of hearing; and nothing is more common in most of the cases of mania.

(For Tasso's case, see Crichton on Madness, vol. ii. p. 40).

It is this state of the ear which often leads to suicide; the unfortunate victim of it imagining that he hears the devil tempting him to self-destruction. One of the most curious cases of this perversion of hearing is related by Dr. Haslam, in his observations on madness.

It is scarcely necessary to say that the eye is also affected; and the hallucinations are usually connected with objects of sight.

(The lecturer here related Colonel Watson's case).

Smelling and touch are equally depraved in mania: of which many curious instances might be adduced were it necessary.

But mania does not always present such features; the permanent delirium is sometimes confined to one object; thence, the disease is termed *monomania*. In this state, when the delirium returns at intervals, instead of running on in the same strain day and night, it is very difficult to detect the disease, unless we be made fully aware of the period when the paroxysm recurs. Individuals thus affected often appear reasonable, when conversing on subjects beyond the sphere of their delirium; and it is in vain to endeavour to perceive their insanity, unless we accidentally, or intentionally, if we are aware of it, touch upon the chord of the mind which is unstrung. In many instances, however, this species of the disease is connected with the same irregular, often desponding state of mind, which exists in moral insanity. Several instances

might be brought forward; I will only notice one described by Dr. Prichard. (The lecturer read the case from Dr. Prichard's work). One of the most interesting instances of this state was related to me by a learned and eloquent friend, who is now one of the Scotch judges. (*The lecturer here related the case of a young lady, whose lover died on the evening she was to have been married*). In this state of the disease, there is apparently less danger to others than in the *mania furibunda*; but this is only apparent: during the paroxysm they often become dangerous both to others and to themselves; and sometimes they are so conscious of this, that they warn those about them, or intreat them to prevent their doing injury.

They are also conscious of the approach of the paroxysm, by a sensation of burning heat, with pulsation within the skull; the pulse is generally full, hard, and strong; the temperature of the skin greater than natural; the bowels are costive, and tormina is often an accompaniment of this state. Patients labouring under monomania are more voracious than those in *mania furibunda*; but sometimes they endure hunger with great pertinacity. According to the doctrines of phrenology, "Mania is not a specific disease, but merely an indication that the disease, whatever it may be, implicates the whole brain and all the faculties of the mind; whilst, in monomania, the morbid affection is strictly limited to one or two of the cerebral organs, and we are informed that the reason why it is so difficult to establish its existence in a court, arises from the patient having often a great degree of control over his manifestations." I cannot venture to offer you any critical opinion upon these remarks, as I really confess that I do not understand them. I will describe to you the state in which the brain has been found, in post mortem examinations, when the disease has proved fatal, after I have taken a brief view of the remaining species of mental alienation.

Melancholia, the next species of insanity, is that form of the disease which is attended with some seemingly groundless, but anxious fear, which plunges the person into a gloomy and desponding state, and frequently leads to the commission of suicide or murder. It is a more common form of insanity than simple mania, and generally arises from mental causes, such as extreme study, religious fervour, love, grief, sorrow, and such like, operating on a habit hereditarily predisposed to the disease.

The corporeal influence of the depressing passions is a torpor in every irritable part, especially in the circulating and absorbing systems; thence the countenance becomes pale and shrunk, and the extremities cold; the pulse is small, and there is a sense of general languor over the whole frame. The pulmonary vessels, from the torpidity of the sanguiferous system, suffer congestion, and

from this cause arises the sensation of fullness or bursting at the heart, which deep grief or sorrow induces. The respiration is slow, laborious, and interrupted with sighs and sobbing, which may depend on the nature of the manner in which the air is allowed, as it were, to escape from the lungs, and the necessity of a deep inspiration to supply the waste, and to relieve the congestion which had taken place on the right side of the heart. In this case, grief seems to act as a directly sedative power, exhausting the vitality of the system, without any previous increase of vascular action. Now, when grief and sorrow are not so great as to produce this sudden depression, but continue a more moderate influence for a great length of time, so much disorder, both of body and mind ensues, as to originate, in a *predisposed* habit, that species of insanity which we have now before us—*melancholia*. When this takes place, the disease may be read in the looks of the patient, though the physician must not trust to this alone. The face grows thin and emaciated, and the muscles weak and relaxed; the adipose support of the eye-balls is greatly diminished, and the eye retires into its socket; the eye-brows are drawn together, and the whole countenance is pale and dejected. The stomach and digestive organs are greatly disordered; pain is felt almost as acute as if gastritis or inflammation of the stomach were present, and is attended with vomiting after every meal; but this may be readily distinguished from gastritis by the pulse, the state of the skin, and the general expression of the countenance; the pulse is seldom quick, the skin generally cold, and the countenance more expressive of dejection and sorrow than pain, and the mind oppressed: it is not wonderful that (the wretchedness of life being the only picture present to the mind) the termination of *melancholia* should be suicide. In such a state, the power of comparing our ideas is lost; yet the self-murderer appears to reason, and to convince himself of the necessity of the crime which he contemplates. He however looks at two points only—the wretchedness of life, the dreary, unpromising, hopeless track which he sees before him, and that relief from suffering which the grave alone is capable of affording; thence his purpose is taken; he forgets every obligation he owes to society, every duty to his Creator, and at once plunges into suicide, to rid himself of the misery of his existence. This state of mind, and the reasoning to which it leads, are most beautifully described by two of the most observing of our native poets, Spencer and Byron.

"What if some little payne the passage have
That makes frayle flesh to fear the bitter
wave?

Is not short payne well borne that brings
long ease

And lays the soul to sleep in quiet grave?

Sleep after toyle, porte after stormy seas,
Ease after warre, death after, doth greatly
please." SPENCER.

"I would not if I could be blest:
I seek no paradise but rest."

BYRON.

Having pointed out the manner in which grief, when long continued, disorders the corporeal functions, and, by constantly preserving one chain of thought, deranges the judgment, and produces melancholia, let us observe the temperament in which these symptoms usually occur, that our diagnosis may still be rendered more easy. The predisposed to this species of insanity are commonly of a dry and lean frame of body, with small and rigid muscles, not filled up in the interstices with fat: a sallow skin, or a complexion of a brownish yellow hue, with little or no red in the cheek: stiff black hair, hollow eyes, and large veins, particularly in the hands and arms, and a constant expression of dejection. As the disease advances these signs increase; the patients become subject to impressions of fear and despondency, and the stomach and digestive organs become depraved: occasionally there is much flatulence, and almost always the bowels are torpid. When the disease is fully formed, the pupils of the eye are often dilated, and the organ itself has a dull, muddy look, and seems to roll heavily on surrounding objects, or it gazes with a fixed unmeaning stare on vacancy. The aduata is often as if painted a dull purplish red; a strong light has a transient effect only on the pupil. The pulse is extremely vacillating, slow and feeble, and sometimes labours. The extremities are always cold: and it is probably owing to this state that the urine is abundant, pale, thin, and cloudless; sleep is rarely procur'd, and when it is present, is broken by visions and frightful dreams.

The general mental characters which we have to look for, to detect melancholia, are anxiety and despondency: a desire to do right, but a feeling which seems to arrest every effort at duty: a strong desire for relief, but despair of obtaining it, and consequent *tædium vitæ*. If suicide be not committed, the same object is attempted by murdering some person; and the victim selected is generally a child or person for whom the melancholic lunatic has a sincere love: and this desire either to commit suicide or murder is one of the most marked distinctions between melancholia, in which it exists, and hypochondriasis, in which it is absent. On this account, no species of insanity requires more close and attentive watching than melancholia, and none so frequently will be brought before you in a legal point of view. It particularly behoves you to caution relatives as to the danger of leaving such patients alone, especially when religious enthusiasm has had some share, as an exciting cause, in the development of the disease.

Religious enthusiasm, as giving birth to deep melancholy, is a common cause of suicide among certain sects in this country. The patient believes that he is deserted by the Almighty, and cannot be forgiven; the continued recurrence of this idea at length brings on a diseased state of the brain; this is followed by despair; and it is the desire of relief which drives the unfortunate individual to commit the crime of self-destruction. In some instances, although few, he believes that he is destined for eternal happiness; he cannot endure the delay which life presents to its accomplishment, and yields to the urgency of the internal impulse. In both cases the patients require to be watched.

But nothing is more common in such cases, than for the advice of the physician to be superseded by some meddling, injudicious friend; and suicide is a general termination of melancholia. (Here the lecturer related a case).

Among the variety of forms in which melancholia displays itself, one particularly demands your attention. That variety which Sauvages terms melancholia attonita is of this kind. The patient preserves an immovable posture, which he never alters unless forced: "if he be seated, he never rises up; if standing, he does not sit down; if lying, he never gets up. Neither does he move his feet except they be pushed aside by a bystander: he does not shun the presence of men: if asked a question he does not answer, and yet he appears to understand what is said: he pays no attention to objects of sight or touch, but seems immersed in profound thought: if food be put into his mouth he will eat; and if liquids be presented he will drink. There is generally present some idea of being cast off or condemned by the Deity."

Another curious form of it sometimes occurs, in which the hallucinations assume that form which in the age of superstition passed for inspirations from the Deity; and which among the multitude are occasionally regarded as such. This is well illustrated in the life of Saint Teresa, as detailed in Butler's *Lives of the Saints*. (See Crichton, vol. 2. p. 451, Appendix).

If we suppose a case of melancholia ending in suicide, and a coroner's inquest assembled, if doubt arises from an imperfect history of the case, it is necessary to inquire what evidence can be procured from the post mortem examination. In general the brain of melancholic maniacs is softer than that of sane individuals; sometimes yellow, gelatinous, or bloody fluid, is found at the base, or contained in cysts formed in the anterior lobes; occasionally the brain emits a peculiar foetid odour; but this often occurs also in the brains of epileptics and idiots. The softness serves to strengthen our diagnosis between mania and melancholia; as in mania, although it is softer than natural,

yet it is less pulpy, particularly in the cineritious part, than in melancholia. Sometimes, when the consistence is natural, the medullary portion is full of bloody points, from the great turgescence of the vessels. In general, the ventricles are enlarged, sometimes to a very uncommon degree, but, on the contrary, these cavities are sometimes much smaller and narrower than usual; this, however, is less common than the opposite state. In many instances fluid is found in the ventricles, but not in all. In mania the choroid plexus is swollen, occasionally containing hydatids, occasionally with ossified spots; in melancholia hydatids are more common. The cerebellum is generally softened to the same degree as the cerebrum; the pituitary is enlarged, and most commonly harder than natural.

When such appearances are observed on post mortem examinations, coupled with the previous history of the case, there is much confirmation of the opinion that the person has laboured under melancholia; and evidence of this becomes peculiarly necessary in proving the validity of wills, as my learned colleague will fully explain to you. With respect to the appearances presented in post mortem dissections in mania, which may be now noticed, it has been ascertained,

1. That no distinction generally exists with regard to the size of the head, between sane and insane individuals; nor is there any peculiarity of form.

2. The skull, in maniacal patients, is commonly very thick; but this has not been observed in melancholics.

3. The *dura mater* adheres strongly to the skull; and yet, in parts, fluid is found between them; this membrane has been found also much thickened, varying in colour, and occasionally ossified.

4. The *pia mater* has been found thickened and studded with small globular, spongy

bodies, and in a few instances ossified. The spongy bodies are situated chiefly under the crown and forehead, sometimes as large as a pea. The ossifications are commonly met with on the anterior surface of the anterior lobe of the brain, on the upper surface of each hemisphere, and on the flat surface lying on the falx. Sometimes coagula of blood are found in the pia mater; but these often occur from violence during the paroxysm.

5. In the *substance* of the brain indications of inflammation are common; sometimes hydatids are found, and occasionally an insupportable fœtor is exhaled on cutting into the brain. Bonetus mentions some cases in which the brain was dry and friable: but this is a rare occurrence. On the contrary, the brain is more frequently soft and pulpy, even to an extraordinary degree.

6. In many instances water is found in the *ventricles*. This has been the case in all the brains of madmen which I have examined: and, in these instances also, the choroid plexus was generally diseased, and often studded with hydatids, particularly when the disease had been accompanied with epilepsy.

7. The *pineal gland* is sometimes found covered with serum; sometimes it is much larger, harder, and more tenacious than natural. Sometimes stony concretions are found in it, but not always.

8. The *pituitary gland* is, in general, harder than natural.

9. In the *cerebellum* the same spongy bodies and ossifications as have been noticed in the brain are also present: the membranes are also thickened and studded with hydatids; and sometimes coagula of blood have been found on the medulla oblongata and spinalis; and the consistence has corresponded with that of the brain.

LECTURES

ON THE

INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE XIV.

Arguments in Disproof of the Vital Principle of Authors.

FIRST, then, with respect to the *existence* of a vital principle, or of life as a substance. The evidences commonly adduced in favour of this hypothesis hinge principally upon the presumed impossibility of explaining either the original organization of a living being, or its characteristic actions when organized, without this admission, and the incompatibility of the opposite opinion with a belief in a future state of existence (a): on the degree

(a) That life is an *Ousia*, an entity or a substance, material or immaterial, resident in

certain aggregations of matter, and the cause both of its organization and of the character-

of validity therefore of each of these alleged evidences, it will now be necessary to say few words.

I. If, then, Organism—it is confidently asked by most of the supporters of the vital

istic actions which it afterwards performs, is the oldest opinion on the subject, having been entertained by almost all the ancient sects of philosophers. The notion of the existence of an Elementary Fire—the soul of the world, the formative and conservative power of all nature—descended from the Brahmins of India, through the renowned Hermes Trismegistus, or Tot, of glorious memory, and the Pastophoric of ancient Egypt, to Thales and Pythagoras, the former of whom studied at Memphis, and subsequently taught philosophy at Miletus, while the latter studied at Thebes, and taught afterwards at Crotona; and it thus became the tenet of the numerous schools which in later times flourished in Greece and Italy, the Academic under Plato, the Peripatetic under Aristotle, the Stoic under Chrysippus, and so forth. By the “learned Theban,” indeed this *Πῦρ καθαρσιον* of the Egyptians had its name changed to *Φύσις*, while by Plato it was called for the first time *ψυχή*, by Aristotle *ἐντελεχεια*, and by Chrysippus *πνεῦμα*, nor were the opinions of these and other celebrated philosophers respecting the nature of this imaginary substance less discordant than the names which they imposed upon it; some looking upon it, like the original propagators of the doctrine, as a kind of fire, others as a kind of air, or ether, or spirit—the breath of life, &c.—and others again as merely a kind of water (Ciceronis Tusc. Quæst. lib. i, § 9, 10). But whatever were its nature, this supposed substance, actuating, as was believed, the microcosm or universe of which it regulated all the motions in the capacity, as it were, of life or soul of the world, was capable of being split or divided into innumerable portions, so that each individual microcosm, or organized being, got a chip of it—a *Derivæ particula aura*—and this in quality of its proper life, in like manner actuated and directed all its proceedings. This idea of the vital principle, in its character of fire, has been immortalised by the story of Prometheus, who is said by the poets to have vivified his clay statues by a fragment of it stolen from the chariot of the sun; and a similar notion was embraced by all the earlier physicians. Thus, by Hippocrates, the human body is described as consisting, not merely of *ισχυρτα* and *ισχυμενα*, of which notice has been taken already, but of *ενορμουνητα* also, which seem to signify nearly the same thing, or the same no-thing, as any one of the terms above specified—so much so that Galen subsequently again employed, instead of it, the term *πνευματα*, from Chrysippus; and having split these *πνευματα*,

as lately mentioned, into three families, under the names respectively of Vital, Natural, and Animal Spirits, to each of which he gave as well as a “name,” a “local habitation,” the first being placed in the heart, the second in the liver, and the last in the brain, conferred a most essential favour on the subsequent physiologists of the vital principle school, by supplying them with a most convenient *Θεὸν ἀπὸ μηχανῆς*, to be always conjured up when any difficulty was to be explained, or at least disposed of. In this way, then, life came to be regarded as a substantial existence, like that coarser kind of fire which was one of the four reputed elements of all things; and as the latter, when it entered into bodies, was represented as the cause, as well of their general physical properties, as of the peculiar phenomena which they displayed during combustion, so the former, on becoming a denizen thereof, was described as the cause, first of their organization, and afterwards of the peculiar actions by which they were distinguished. And this view of the matter was perhaps the most natural to man in the infancy of philosophy, impressed as he was, from the first, with the idea that all matter—at least all the grosser forms of it—were essentially inert, and of course disposed therefore to ascribe all spontaneous motion to a union with the thing moved of some substantial moving cause. It was not easy even for the most exalted geniuses, with so limited a knowledge as they then possessed of the essentially different properties resulting from differences in the composition, substance, and aggregation of different forms of matter, to do otherwise than attribute the distinctive actions of organized beings to some hidden principle operating within them, of which inorganic matters were destitute; but it might have been expected that such vague surmises as this would long before this time have sunk under a more enlightened philosophy, and that life as a substance would long since have shared the same fate as fire as an element. Such however has not been the case, the notion that life and living action are quite distinct, the former being the substantial cause of the latter, having descended from the authors above enumerated, first through Van Helmont, who, as he could not of course use any word which had been employed by Galen, chose to substitute the term *Archæus*, borrowed from Paracelsus, for the *πνεῦμα* of his more orthodox predecessors; Harvey, who returned to the term *ψυχή*, or *anima*, which, as before observed, was represented as [of two kinds, vegetativa and sensitiva; Borelli, Stahl,

principle doctrine—be the cause, either *per se* or in conjunction with any other condition of life, what is the cause of organization, or that process from which organism resulted? Can any known chemical or mechanical forces give rise to so specific a composition, so

who continued the title and still further extended the powers of the said anima; Carl, Corchwitz, Swammerdam, Whytt, Sauvages, and Barthez, the first to familiarize physiologists to the term vital principle; to Fryer, John Hunter, the first to attempt to identify this supposed principle with electricity; Plenck, Platner, Hufeland, Sprengel, Brandis, Schmidt, and other writers of the close of the last century, from whom it has been transmitted unadulterated, by Abernethy, Pring, Barclay, Copland, Good, Davies, and others, down to our own times; and we are still condemned to hear the terms vital spark, vital spirit, vital principle, and so forth continually used, not only by the vulgar, but by philosophers of eminence, as referring to something which has confessedly a real and substantial existence; and the human body is still sometimes described as consisting of solids, fluids, and a vital principle, almost in the same words as had been employed between two and three thousand years ago by Hippocrates. With respect to the modifications of this notion entertained by those who have most recently written on the subject—and it seems quite superfluous to go further back than the present century—Mr. Abernethy, who treads everywhere so closely in the footsteps of John Hunter, believes of course that life is if not identical with, certainly analogous to electricity or galvanism—(On Mr. Hunter's Theory of Life, 1814); but the refutation of this unfortunate hypothesis may be advantageously deferred till the subject of electricity or galvanism, as a stimulus to irritability, falls to be considered: in the mean time it is sufficient to say of it, that any thing more vague and visionary has never hitherto obstructed the progress of physiological science. By Dr. Pring, on the contrary, the vital principle is represented as a substance quite *sui generis*, and he speaks of a "sum and quantum of life," with as much confidence as if it could be meted out by the help of a pair of scales, or a glass measure; while it is an inference from his hypothesis, that, as life is on the one hand, a cause of organization, so organism is, on the other, a cause of life, since the substance of life is continually renewed, he assures us, "by the assimilation of its identity from the blood." (On the Laws of Organic Life, 1819). But, if the substance of life be renewed from the blood, it must either have entered the blood in propria persona, with the air or food, in which case the said air or food ought to be alive, or it must have been formed by the blood, in the manner of a secretion; and from what ingredient of the blood secretion can pro-

duce *de novo* a simple substance, material or immaterial, remains to be explained. But perhaps the substance of life is not simple—and, indeed, we are told that "the influence of life is to separate from the blood those *elements* which constitute its own identity; and elsewhere, that "animal heat is a part of the principle of life." *Elements* and *parts* of a *principle*—*material ingredients* of that which even those who look upon it as substantial still generally consider as *immaterial*! But it is mere waste of time discussing such "verba et voces prætereaque nihil" as these. Dr. Barclay's work (On Life and Organization, 1822) extolled, as it has of course been, by those who advocate similar opinions, consists, not so much of a statement of arguments in favour of the existence of life as a substance, as of a parade of authorities on the question whether life be the result of organism, or organization—whence organism springs—be the result of life a question only indirectly connected with the one at issue; since, although most of those who contend for the existence of life as an entity, adopt the latter opinion, there are of them, as above observed, who still imagine, like all those who deny this existence, that organization is independent thereof, and believe that life does not enter the being till its organization has been effected. Dr. Barclay is not of these; but presuming on the existence, from the first, of a principle, which may be called indiscriminately vital, sensitive, rational, or immortal—a most unfortunate, but very unusual jumble—indulges in a tirade of somewhat captious abuse of the head and heart of every body—in particular of Blumenbach, Cuvier, Cabanis, and Lawrence—who presume to differ from him, and whose tenets he vaguely conceives likely to interfere with "the raptures of Moses and the Lamb." (p. 399). Dr. Barclay was an excellent anatomist and an excellent man; but, as good anatomists and as good men as he, have entertained, and still entertain, very different sentiments on these matters. Dr. Copland, unlike some certain of the fraternity above alluded to, derives his principal argument in favour of the existence of a vital principle from the presumption that it is essential to organization; but to this an answer is attempted above. (App. to Richerand's Physiology, 1824). In the same track follows Dr. Mason Good—a name hardly less notorious in physiology, than eminent in literature—who, in ridicule of the doctrine that life has no real existence, which had become by this time rather inconveniently prevalent, facetiously remarks, "the human frame is hence a barrel-organ,

complicated a substance, so heterogeneous an aggregation, or so determinate a body, as those which characterize an organized being? It has been conceived, indeed, even by some of the supporters, on other grounds, of the doctrine in question, that such may be the case, and that the substantial life may not perhaps enter such a being till it has become organized by other means (*a*); but it may be safely conceded to the most unmitigated substantialist that no such chemical or mechanical powers are competent to produce such an effect. It has been already shewn at some length that the chemical composition of organized tissues is quite distinct from that of merely chemical compounds, and consequently that the first step towards organism requires powers different from those by which inorganic matters are formed. It requires life, but not a living principle. It requires the life, or living action (*Zoē*) of the thing *organizing*; not any living principle (*ψυχή*) in the thing *to be organized*. It has been expressly stated lately, that organized beings can be formed only by such as are already organized, the existence of any one implying always the pre-existence of some other; and that the forming and separating from themselves, each in its generation, such new

possessing a systematic arrangement of parts, played upon by peculiar powers, and executing particular pieces or purposes, and life is the music produced by the general assemblage or result of the harmonious action." (Study of Medicine, 1825, vol. iv, p. 44). He could not possibly have illustrated the nature of life, consisting, as it does, in the proper actions of *organized* beings, better—"We thank thee, Jew, for teaching us that word." Dr. Pring instructs us only how the substance of life is continually renewed, but Mr. Davies, in some otherwise excellent papers, in a medical journal, teaches us how it is subsequently disposed of, assuring us that "it combines with the structure by means of affinity, as well as forms that structure by the same power," (London Medical Repository, 1827), a circumstance which it must be extremely gratifying to every body to be aware of, particularly as it is so satisfactorily demonstrated. Dr. Alison, in his recent work, avoids, perhaps judiciously, entering into any discussion respecting the nature of life; a word which "does not," he inadvertently observes, "denote a simple idea, and, therefore, cannot be defined," (Outlines of Physiology, p. 1), a diametrically opposite reason being offered, with more propriety, a little further on (p. 151), for not attempting a definition of sensation or thought. He is obviously inclined, however, to regard life, not indeed as any thing material, but still as an entity, since he describes organization as one of its effects; and accordingly we find his reviewer stating, in opposition to the more modern opinions concerning the nature of life, that "it is a sad confusion of all etiological relations, which ascribes to the passive and naked effect, the very existence of the agent to which this effect owes its being." (Medico. Chir. Review, 1831). Still more recently, also, Mr. Thomas, in allusion to the same doctrines, has observed, "We have first the effect, and secondly the sum total of the effect entering into an unnatural conspiracy to produce, by an *ex post facto* operation, a cause for an antecedent operation." (Liverpool Med. Gazette, 1833). Now, this is precisely what we *have* in the entity view, and what we *have not* in the

non-entity view of the matter in question; for in the former we have, first, life (*ψυχή*) represented as forming the structure, and then the structure represented as forming life (*ψυχή*), whereas, in the latter, life is admitted as an effect alone—as a *Zoē*; and it is only, therefore, upon the unjustifiable petitiō principii that life exists as a *ψυχή*—the *q. e. d.*—the very point at issue—that these objections are founded. There needs no ghost come from the dead to tell us that an effect cannot be the cause by which that effect was produced; but, had the opponents of the latter view of the matter understood the doctrine which they impugn, they would have known that life is regarded by its advocates, not as a cause of vital action, but as identical with it, the cause being the co-operation of a certain property and certain powers, both quite distinct from life in either sense of the word. That there is any evidence whatever of the existence of any substantial cause of this action—of the existence of life as an entity—those who maintain the opposite opinion are satisfied with denying, the *onus probandi*, resting of course with those who assert, not with those who deny the proposition. It might otherwise be shewn that the admission of this hypothesis brings with it many more difficulties than it removes; and that innumerable phenomena, which are easily explained without it, become quite inexplicable if it be admitted—but it is idle making giants merely for the purpose of killing them.

(*a*) This appears to have been the opinion of not a few of the authors lately enumerated as advocates of the vital principle doctrine, and the list might have been swelled with the names of Descartes, Needham, Darwin, Priestley, Fray, and many more, who, while they in general ascribe the proper actions of an organized being, when formed, to the presence of such a principle, still consider its formation to depend upon certain chemical affinities, formative appetencies, and so forth, quite independently of its operation. The general question, however, at present is—not whether life, considered as a substance, perform all that has been attributed to it—but, whether it be a substance at all.

beings is one of the characteristic actions—that is to say a part of the life of plants and animals in general. The organization then of the embryo, or the process by which a new being possessed of organs, however rude, and, in virtue of its organism, indued with irritability or vitality, is formed, is the work of the parent. Nor does there appear to be any greater difficulty, as lately observed, in conceiving this particular application of the process of secretion, than in understanding that by which every organized being, not only continually renews, in proportion as they are removed by absorption or other means, its own natural organized tissues, and sometimes whole organs, but also frequently deposits new ones, each of which is equally indued with irritability or vitality as those germs which are the rudiments of beings of a future generation: nay, the difficulty is in fact less in the case of such germs, than in that of which are called false growths, in general; since, in the former case, we have to comprehend only the organization, or the formation by secretion of the rudimental structure in question, whereas, in the latter, we have to comprehend further the mode by which, at first distinct, as already described, from the parent animal, it subsequently becomes a part of it. The germ then so formed by a vital action of the parent, and possessed, in virtue of its primordial organism, of the property of irritability or vitality, maintains from the first, by the co-operation of this property and the natural stimuli by which it is excited, a series of actions constituting its life; and it is by one modification of these actions, as effected by a supposed specific force, which has been signalized by the name of plastic power, and so many others elsewhere specified, and not by any substantial vital principle that its full elaboration is effected. It is by this that in animals are formed, by means of the parenchyma laid down from a very early period in the apparently homogeneous germinal membrane, first the three principal layers of the latter, and subsequently all the tissues and organs of the body in a certain definite series; so that, though the organization of the embryo was the work of its parent, its organogeny is its own, and parts which it received from the former in a state of diffusion and ambiguity, itself renders concentrated and determinate. But if the embryo be thus organized by its parent, how, it may be asked, was the first parent organized? With this problem the physiologist, in the strict sense of the word, has nothing whatever to do. The Almighty Creator—the first and the last—willed that, not only the inorganic, but the organized kingdoms of Nature should exist; but how either the one or the other was originally called into being He alone knows, who said “Let there be light—and there WAS LIGHT”—

*“ Whose word leaps forth at once to its effect—
Who calls for things that are not—and THEY COME.”*

It may be observed, however, that the solution of the problem, how the first organized being of every species was formed, founded on the presumption that certain aggregations of matter, however effected, became indued, in virtue of this aggregation, with a distinct property, giving rise, under fit circumstances, to the phenomena of life, is at least as simple and satisfactory as that which assumes that it was by life, as a distinct substance, entering into matter, that these aggregations of it were effected; and that the latter implies a greater infringement of the law *οὐδὲν ἐξ οὐδενος* than the former, is sufficiently obvious.

But a monad, it is alleged, that is a globule of organic matter or presumed organic molecule, which cannot have even so rude a distinction of parts as is essential to organism, may still display some of the phenomena characteristic of living beings; and in fact such, it is said, are displayed in the union of these globules—as in the process of constituting the mould and animalcules of infusions of organic matters—to form those very parts, the pre-existence of which is, on the other hand, considered necessary to give rise to irritability or vitality. This objection however to the doctrine which deduces vitality from organism has been incidentally replied to already, by the refusal to admit that these globules are organic molecules, or that it is from a union of them that the mould and animalcules which are developed during the decomposition of organic matters result. Their origin is in all probability, like that of all other plants and animals, from perfectly organized germs (a); nor does their extreme minuteness furnish any fair objection to this presumption—nay, for any thing we know to the contrary, myriads of similar germs may harbour in one such globule of extractive or sodo-albumen as certain authors have been pleased to look upon as a monad. What must have been the size of the germ which is to become an individual of the last generation of man, if, as supposed by some physiologists of the highest eminence (b), it existed ready-made in the ovary of the first mother?—nay, what must have been that of the germ which is to become a parasite destined to infest this individual, if this also, as has been likewise conjectured, existed within the former from the creation? But, reconcileable as all this is with the first principles of physical science, by which we are taught to regard matter as infinitely divisible, imagination turns dizzy at speculations like these. The common-sense view of the matter appears

(a) Ehrenberg, Arch. Gén., 1834.

(b) Haller, Bonnet, Spallanzani, &c.

to be that every organized being is secreted, in a rudimental state, by a pre-existing organized being—whether of the same, or of a different species, as in the case of parasites—that it possesses from the first, not indeed the rudiments of each individual organ as it is in future to appear—a doctrine which is quite incompatible with the frequent metamorphoses which most of these organs are now known to undergo during their progressive development—but a rudely organized structure, in virtue of which it is indued with a property which enables it, when acted on by appropriate powers, first to form in every part of the apparently simple germinal membrane, its own parenchyma, by the agency of which all its distinct tissues and organs are afterwards gradually and simultaneously deposited; and, having thus attained its mature structure, to display all the other phenomena of life, including that of in its turn secreting other organized structures, which, when again acted on in a similar way, again go through a similar process.

II.—It is however chiefly the singular and apparently anomalous nature of the characteristic actions of organized beings, when mature, which, as it first introduced, so it still serves to perpetuate the vague notion of some distinct substantial principle as their cause. A corpse which has just ceased to live—that is to say, to display any of those peculiar phenomena in which life consists—respiration, circulation, nutrition, secretion, absorption, and so forth—cannot, without an effect, be conceived to have undergone so great a change, without having lost something substantial which it previously possessed, and which was the cause of its living. But if we reflect on these actions, anomalous as they appear, what do we find them in fact amount to but certain movements of either particles or masses of matter, not certainly identical with, but still very analogous to those which, in inorganic matters, we call chemical and mechanical, and which we are contented to ascribe, not to any substantial principle of action, but to certain properties and powers resident in these matters, the reciprocal action of which gives rise to what are called attraction and repulsion; and why need we hesitate to admit that similar, though not the same properties and powers may, in organized beings, be competent, while they are in mutual co-operation, to effect those actions in which life consists, and which of course terminate on the cessation of this co-operation, as the ingredients of a chemical compound cease to be agitated when their affinities are satisfied, and a watch stops when either the susceptibility of motion in its wheels is destroyed, or the requisite power ceases to operate upon them? It is true a living being appears to acquire no such repeated additions of new ingredients as a chemical compound, and no such frequent winding up as a watch, to avoid falling into the soon-established repose of the particles or masses of inorganic matter; but we must keep in mind that, in the latter case, while the properties and powers of the substances in co-operation are soon satisfied and exhausted, there is no inherent renewal of these substances, and, with them, of these properties and powers to renew their proper actions, whereas, in the former, it is the specific end of some of these actions to give rise continually to new aggregations of matter, distinguished by the same properties, and acted on by the same powers, as the old which have disappeared; so that the conditions of continual action are never for an instant suspended. It is not then that there is, in living beings, no addition of new ingredients, and no winding-up, but that this addition and this winding-up are incessant; and all that death implies, therefore, is a cessation of these as the necessary conditions of life or living action, not any abstraction of life, in its character of a substantial vital principle on which such action depended.

Observations on the Treatment of Strangulated Hernia, with a Case illustrative of an unusual form of that Disease. By John Jacob, M.D., Surgeon to the Queen's County Infirmary, and to the Maryborough District Lunatic Asylum, &c.

To the Editor of the Original London Medical and Surgical Journal.

SIR—My attention has been for a considerable length of time, at intervals, occupied by the consideration of the relative value of the different means adopted for the relief of strangulated hernia. Of these the taxis must, in my opinion, be considered as the principal and most effective, the others being chiefly directed to assist its action, or diminish the amount of obstruction it is intended to overcome.

On being called on to relieve a case of strangulated hernia, the first impulse of the medical attendant is to restore the bowel to its natural position in the abdominal cavity, by a manual effort. Should he fail, he then calls to his assistance those means best calculated to diminish the rigidity of the several openings and canals through which the bowel must pass; to remove the resistance offered by muscular contraction, as well as by a distended state of the abdomen generally, or of the portion of the bowel contained within the stricture, whether resulting from the presence of flatus, or from a loaded condition of the intestinal canal; to excite the peristaltic movements of the intestines themselves, with a view to the disengagement of the constricted portion, by the action of the muscular fibres of the bowel; or to induce a degree of contraction in those parts which envelope the sac, and thus aid

the efforts of the operator towards reduction.

A consideration of the structure of the different apertures through which inguinal or femoral herniæ make their escape, must satisfy us that by position alone can we expect to relax them to any extent—fomentations may have an effect, but I do not think that any person who has ever divided the stricture of a strangulated hernia can be persuaded that such applications as extract of belladonna can be really productive of benefit. As the effect of position is a matter of some importance, I will defer my observations upon it till I come to remark fully upon the taxis.

Muscular contraction presents a serious obstacle to the reduction of hernia: the patient can with difficulty be prevented from retaining his breath and straining violently when any attempt at reduction is made: the opposition thus afforded may be estimated by a consideration of the difficulty with which a reducible hernia can be retained in the abdomen of an infant while crying. How much more powerful must be the efforts of a full-grown man straining with all his force! The subjugation of these efforts constitutes one of the great advantages resulting from the use of those remedies calculated to induce muscular relaxation. Fomentations, the lancet, and warm bath, will, in the first instance, be had recourse to, when it has been ascertained that the hernia cannot be readily reduced, fomentation being eligible from first to last, unless when it may be found necessary to supersede it by the application of cold. The use of the lancet must, of course, be regulated on the same principles as in other diseases, due caution being observed with old or debilitated patients, with persons of broken down constitutions, and in those cases which have been permitted to run on for some days without assistance. The use of the bath is regulated on similar principles, both being intended to reduce that prostration of the muscular powers which presents the most favourable opportunity for reduction.

No time should be lost in endeavouring to induce the bowels to act. Purgatives, by the mouth, are often administered with considerable advantage. I can by no means coincide with those who regard them as objectionable, and calculated to increase inflammatory action, when judiciously regulated; if extreme irritability of the stomach exists, or if the progress of the case be far advanced, they must be used with considerable circumspection. Injections are unattended with any disadvantage, and should be perseveringly persisted in, till relief be obtained, or the operation is had recourse to. My custom, for some years, in cases of obstinate constipation, as well as in those of strangulated hernia, has been to introduce the œsophagus tube of the stomach pump as far as it could reach. The

large intestines, indeed the whole course of the intestinal canal, below the stricture, can thus be emptied of their contents, by which the abdominal parietes are rendered more flaccid, and the obstacles to reduction considerably diminished. It is very desirable to remove the accumulated gases, and this object is most readily effected by the introduction of the tube. I cannot, however, coincide with the opinion of Mr. O'Beirne, who has, in his work on Defecation, more particularly directed the attention of the profession to the advantages attending the introduction of the flexible tube, in supposing that the removal of flatus from the intestines will usually be followed by the escape of that contained in the strangulated portion of the bowel, and consequent reduction. When we bear in mind the yielding nature of the intestinal canal and abdominal parietes, we cannot suppose that the accumulation of flatus presents so very serious an obstacle to the reduction of hernia, that its removal will in many cases be sufficient to effect that object. It has, I perceive, been recently proposed to discharge the flatus from the strangulated bowel, by means of a very fine trocar and canula, but I can scarcely imagine that such a practice is likely to be generally adopted; for were it even altogether unattended with danger, which I cannot suppose, I am by no means satisfied that the emptying of the bowel of its gaseous contents *in that way*, could be considered advantageous. It is most desirable to discharge the flatus from the hernia, along the intestinal tube, as it tends more or less to dilate the stricture in its progress, and is generally followed by complete reduction. For the emptying of the bowels below the stricture, whether of their gaseous or more solid contents, the use of the gum elastic tube, and the administration of enemata by means of it, will be generally found sufficient. The tubes sold as Mr. O'Beirne's, with the enema apparatus, are not, in my opinion, sufficiently long: the œsophagus tube answers the purpose better; the orifice in the point of Mr. O'Beirne's is an advantage, and can be readily made in the common stomach tube. Some difficulty is occasionally encountered in the introduction of the tube, which may be found to hitch against the promontory of the sacrum and then fold upon itself in the rectum; it may, however, be directed by the finger introduced as high into the bowel as it can reach. Should the obstacle be situated higher up, it will be best surmounted by throwing in part of the injection, pressing the tube gently forward at the same time, and repeating this manœuvre as often as its progress may appear arrested. After it has been satisfactorily introduced, it is better to allow it to remain for some time, for the purpose of throwing up an injection when necessary: an intelligent attendant should sit beside the bed, and keep a finger applied on the orifice, to regulate the escape of the

contents, permitting flatus or feculent matter to be discharged, or causing the injection to be retained sufficiently long to produce its effect. A quantity of warm water may be occasionally thrown up, which will have the effect of encouraging the intestine to contract; and, in cases of obstruction of the bowels from accumulation, may have the effect of detaching scyballæ or other injurious collections. It has been even suggested that the suction of the pump may be made available for the purpose of clearing out the bowel, but this attempt should be very cautiously made, as the intestine would be very liable to come in contact with the eye of the tube, and might be, consequently, injured. A very poor man, far advanced in age, has been in the habit of coming, from time to time, to the county infirmary to seek relief from obstruction of his bowels; on three occasions he presented himself labouring under all the symptoms of intussusceptio, which had remained some days unattended to, and his condition was most unpromising, the vomiting and hiccough being so constant that purgatives could not be retained on the stomach. He has been invariably relieved by the use of the long tube, the enormous distention of the abdomen being immediately reduced by a long-continued discharge of a considerable stream of gas, which followed its introduction; an injection being thrown up, the bowels were readily induced to act, and the patient quickly recovered. An almost incredible accumulation of potatoe skins was found to be the cause of this poor fellow's sufferings—and many are the evils entailed upon the impoverished peasantry of this country by the wretched diet with which their unenviable existences are sustained. For infants, a moderate-sized gum elastic catheter, adapted by a brass top to the enema syringe, will be found very convenient. The tobacco enema possesses the double advantage of inducing that degree of debility and muscular prostration which facilitates so materially the successful application of the taxis, as well as of exciting the peristaltic action of the intestines, which has in itself been found sufficient to withdraw the bowel within the abdomen. In cases of obstinate constipation, unattended with hernia, it will also be frequently found to relieve the patient when all other remedies may have failed. It is, however, to be regretted that its effects are so uncertain that they cannot be reckoned upon with precision, some individuals experiencing but little change, while others suffer alarmingly under its influence. It must, nevertheless, be regarded as a powerful agent in the treatment of hernia, to which recourse should generally be had before proceeding to operation. It had better be administered by means of the common pipe, as it would not be desirable to throw it up too high.

Cold applications, whether composed of

pounded ice, or refrigerating mixtures, are highly beneficial, as well by keeping down inflammatory action, as by inducing a degree of contraction in the envelopes of the hernia, which has been occasionally found sufficient in itself to effect reduction.

Of all the means at our disposal, the taxis must be considered by far the most efficient in the treatment of this formidable disease. To direct particular attention to this subject is the principal object of this paper, for I fear that there are many surgeons who do not consider it, what it really is, as the sheet anchor on which they are to trust. I believe it too often happens that the knife is had recourse to in cases which might be relieved by the judicious application of the taxis. Many surgeons feel too great timidity in the application of the necessary degree of force, lest they might rupture the intestine; and others, if they do not find their efforts quickly successful, abandon them too soon. The degree and duration of the force which may be used must be in a great measure regulated by the condition of the hernia and the length of time during which it may have been strangulated. If it has been for some days in a state of constriction, and that there is consequently much reason to apprehend that a tendency to gangrene may exist, the utmost caution must of course be exercised, as the bowel may be expected to give way under a comparatively moderate degree of pressure; if the symptoms of strangulation have been present for many days, if the hernia be discoloured, and gaseous infiltration of the cellular tissue has taken place, it becomes a subject of grave consideration whether the taxis be at all admissible; and if these symptoms are accompanied by that cessation of pain, frequent hiccough, and alarming sinking of the powers of life, which render the nature of the case still more unequivocal, its application cannot, of course, be ventured upon. If, on the other hand, we have the advantage of seeing our patient early, we can have recourse to the taxis with a degree of confidence which will materially conduce to its success. Whenever we are about applying it, the patient should be placed in the position best calculated to relax the abdominal parietes and the several apertures through which we have to return the hernia. The flexion of both thighs to right angles with the trunk, and the rotation inwards of that belonging to the side at which the hernia may exist, will generally be found sufficient for this purpose; the elevation of the pelvis, if readily effected, would also be attended with advantage. One hand should then be applied over the surface of the hernial tumour, and a general degree of compression made over its entire extent, the pressure being at first very inconsiderable, but afterwards increased to that degree which the necessities of the case may require; the thumb and two first

fingers of the other hand should at the same time be applied as near the neck of the sac as possible; with these also a considerable degree of pressure may be made, and progressive movements performed in the direction in which we are anxious to forward the hernia, as it were, "bit by bit." The application of a steady, increasing, and long-continued pressure over the surface of the tumour, is by no means the least important part of the proceeding; it tends, not merely directly to reduce the hernia, but, should there be delay or difficulty in effecting this object, it will assist in mechanically dilating the stricture, by the application of an expanding force, by means, if the hernia be intestinal, of the pressure of its contents, whether gaseous, fluid, or more consistent, acting from within it, on the same principle as the plan proposed by Arnott for the dilatation of strictures of the urethra.

Another effect to be expected from it is a diminution of the thickened, I may almost say oedematous, condition of the contents of the sac so commonly observed. This pressure should be kept steadily applied with but little intermission; the efforts at the neck of the sac being from time to time repeated, its amount may be in some degree regulated by the nature of the contents of the sac, as it may be much more freely used if there be reason to suppose that the hernia be omental rather than intestinal; percussion will be found useful in assisting the diagnosis. It will often be found that under the diffused pressure the hernial tumour will become slowly and insensibly somewhat softer and more flaccid: when this is observed, its speedy reduction may be confidently anticipated, and will be forwarded by the use of the second hand placed at the neck of the sac. Moderate experience in the careful application of the taxis, in cases of strangulated hernia, will enable the surgeon to form a pretty accurate opinion of the probability of reduction without division of the structure; but it is only from attention and practice that this tact is to be acquired. If the hernia be small, and of firm consistence, a much shorter period of time will determine whether relief is to be obtained without operation. Pressure may be applied more directly, and with greater force, than if it were of a larger size; the slow dilatation of the stricture, by the action of diffused pressure over the surface of the hernia not being to be expected. In the small firm hernia, reduction will commonly take place suddenly, and with a jerk; in the larger, the effect will generally be more gradual and slow. When we find it continues firm and unyielding, after a careful application of the taxis shall have been for some time persevered in, obstinately to follow it up would be most injurious. It is the use, not the abuse, of the measure which I recommend, and I am induced to do so from having been called on, in more cases

than one, to assist at the division of the stricture, when I succeeded, with comparatively little difficulty, in reducing the hernia, without having recourse to the knife. It appears that the value of the taxis, and the importance of a careful and persevering application of it, have received in France that attention which they merit. In the *Journal des Connaissances Medicales*, for January, 1834, will be found a description of the mode adopted by M. Amussat for carrying it into effect, from which I have translated the following extract* :—

"The patient should be placed in such a position that the pelvis shall be as high, and the base of the thorax as low, as possible. To effect this, he may be placed upon a plane, considerably inclined, formed of a mattress doubled, the upper fold extending beyond the lower, the inclination being, if necessary, further increased by the use of pillows or bolsters. The buttocks of the patient should be settled on the thick part of the mattress where it is doubled together, and the trunk extended along the inclined plane, which the remainder of it forms. The head should be slightly flexed upon the chest by means of a pillow, the thighs bent to relax the abdominal parietes, and the entire body slightly turned on the unaffected side. The operator, stationed at the affected side, should embrace the tumour with both hands, knead and handle (*la manier*) it, performing a species of alternate traction and compression. This manipulation, performed at first slightly and with precaution, should insensibly be rendered more and more vigorous, without however inducing too much pain. It is indispensable that the manœuvre should be light and gentle at first, becoming gradually more powerful, and that it shall be steadily, and without relaxation, persevered in till the reduction be effected. It must be perfectly understood that the pressure should be neither abrupt nor jerking, all efforts being directed in the course of the passages through which the hernia may have escaped. Both time and patience are essential to the success of the operation, and other means, such as baths, bleeding, leeches, cold applications, &c., may be called to our aid, as being by no means prevented by the proposed plan. Experience will however prove that it is in itself abundantly sufficient to effect a cure."

A case follows of a strangulated hernia of four days' standing being reduced by a laborious application of the taxis, in the manner above described, for an hour and a half, the efforts of two other surgeons having previously proved unavailing.

I will conclude this paper, which I have endeavoured as far as possible to condense,

* I quote from *Encyclographie des Sciences Medicales*, Fevrier, 1834.

with a view to rendering it more suitable for a weekly periodical, by the recital of a case of congenital hernia. of unusual occurrence, which I recently had under my care.

I was called, on the evening of the 30th of November, to visit a farm labourer, named Michael Whelan, aged twenty-one, who, while walking to chapel, about twelve hours previously, became suddenly attacked with violent pain in the lower part of the abdomen, which was immediately succeeded by severe vomiting, and he was compelled to seek assistance in an adjoining house, where I found him. The symptoms increasing rapidly, a gentleman resident in the neighbourhood abstracted a large quantity of blood, and administered a dose of castor-oil with spirit of turpentine, in the forenoon. Pain intense; vomiting frequent; no dejection during the day. When visited by me, his agony was extreme; pulse rapid, small and hard; abdomen tender, and its muscles extremely rigid; constant vomiting. On examination, I found in the right inguinal region an oval tumour, extending from within about an inch of the anterior superior spine of the ilium nearly to the external abdominal ring, flattened, with an undefined margin, tense, slightly elastic, emitting an indistinctly tympanitic sound on percussion, and very tender; it appeared to occupy the inguinal canal, but extended beyond the internal ring towards the spine of the ilium. The external ring was small and rigid, unoccupied by the spermatic chord, nor could the right testis be found in the scrotum. Patient was incapable of stating whether the testis had ever descended, or, if it had, when it might have disappeared. The case appeared involved in some obscurity; it might be one of strangulated hernia, or the symptoms might probably depend upon an inflamed condition of the testis impacted in the inguinal canal, the surrounding parts participating in the disease. I made a careful application of pressure, with a view to its reduction, should it be hernia: the effort proving unsuccessful, I immediately removed him to the infirmary in my gig. On his arrival he was somewhat exhausted from the drive: I had him placed in bed, and again made another ineffectual trial of the taxis: I however had not recourse to it with as much confidence as if the case were one perfectly clear. *Applic. hirudines, xxxvj. tumori et foci tepidi abdomini. Hirudinibus elapsis descendat in balm. tepidum postea repetr. foci. Injiciatur enema cathartm. statim et repet. alternis horis donec respondt. alvus. R. Pulv. Scammonii gr. x. submur hydrarg. gr. v, ol. croton guttam. Theriacæ, .q. s. ut fiat bolus, M. Cap. tal. 4tis horis ad effectm. Dec. 1st, 9. A. M. 34 leeches applied, bled freely, remained 25 minutes in bath of 98 degrees. Considerable debility induced; taxis again adopted without effect; had on before the*

other, after the bath; steeping continued till 4, A. M., during which time, the leech bites, bled freely. Has had three boluses; passed a very restless night, suffering from violent pain, and frequent vomiting of a greenish fluid. Expression of countenance much more anxious, p. 124, small and hard, thirst urgent, occasional singultus. Taxis again attempted in vain. A pupil was placed at the bedside to keep up a constant pressure on the tumour, by means of a soft sponge; fomentation of abdomen continued. 2 p. M. No remission of symptoms. Expression of countenance more favourable, eyes sunken, considerable blueness and shrinking of features; vomiting and hiccup much more frequent, discharge from stomach of feculent character, considerable tympanitis. Tongue dry, thirst urgent: when gratified succeeded by immediate vomiting, p. rapid and small, tumor more tense and unyielding, tympanitic sound on percussion more distinct. Pressure by means of the sponge kept up since last report. Another trial of the taxis, which having proved ineffectual, I decided upon immediately proceeding to the operation.

I made a free incision through the integuments along the entire extent of the tumour, from within an inch of the spine of the ilium, downwards and inwards to the spine of the pubis, traversing the situation of the external abdominal ring; the superficial fascia having been exposed, was also divided to the same extent upon a director; some cellular tissue having been removed, the external ring and aponeurosis of the external oblique muscle were exposed; in the course of the dissection, the superficial epigastric and external pudic arteries were divided and secured by ligatures. I cleared the abdominal ring, which was merely occupied by a small quantity of adipose substance, and having introduced a director, I dilated it for a little better than half an inch. I passed my finger into the inguinal canal, which I found distended by a turgid cyst containing fluid. I extended the opening in the tendon for about two and a half inches; the tumour, which instantly sprung out, proved to be the tunica vaginalis testis, distended to the size a large goose egg, of a dark purple colour, containing with the testis a portion of intestine, a considerable quantity of bloody serum, and some gas. Having laid it open, a considerable knuckle of small intestine presented itself, of a dark colour and much thickened; immediately behind this, lay the testis, somewhat enlarged by inflammation. I introduced my finger to the neck of the sac or tunica vaginalis, and found a remarkably close stricture above the edge of the transversalis muscle; with some difficulty, I introduced my nail within it, and upon this a very narrow Cooper's bistoury, and without further difficulty divided it; the patient expressed himself as instantaneously re-

lieved, and the intestine was readily returned. I endeavoured to draw down the testis towards the external ring, but could not succeed; it was indeed pretty obvious that it never had descended into the scrotum. Under these circumstances, I deemed it more prudent to return it into the abdomen. Having done so, I still found that the tunica vaginalis, which had undergone so much distention, could not be prevented from hanging loosely into the wound. I conceived it best to remove it, which I accordingly did, to within about half an inch of the testis. I closed the wound with three sutures, and slips of silk plaster*, applied a dosil of wet lint, and placed the patient in bed with the limb in a flexed position.

Immediately after the operation, reaction took place, the countenance became composed, the skin warm, and the pulse expanded to a full and free beat, and patient enjoyed some sleep, for the first time since the setting in of the disease. 9 P. M. Reaction increased considerably in the course of the afternoon. Face became flushed, skin hot, and circulation excited; occasional vomiting. Having had no dejection, a purgative enema was thrown up at seven o'clock, which was soon succeeded by a couple of feculent stools, and caused considerable relaxation of the abdomen. The inflammatory action not having, however, subsided, 24 ℥ of blood were abstracted at eight; the pulse yielded; considerable debility but no syncope was induced, and patient now feels cool and comfortable.

Dec. 2d, noon. Slept well, free from pain, no vomiting, considerable fever, headach, countenance flushed, skin hot, respn. 36, p. 132, full and hard. Tongue furred, thirst urgent, dej. v, fluid. Wound in good position; appears to be uniting along 9-10ths of its extent. Lavantur facies thorax et artus superiores subinde, 5, P. M. Much relief from sponging, slept a good deal, heat of surface and headach diminished, thirst less urgent, p. still accelerated. No dejection. 9, P. M. profuse diaphoresis at six, sponging discontinued in consequence, slept at intervals, headach diminished, p. 112, full and soft; respiration 34, skin hot and soft, but free from perspiration at present. No dejection. R̄. pulv. Jacobi, gr. v; submuria. hydrarg. gr. iij m. capiat statim etsi opus sit crasumat. mist, cath. ℥ iv. summo man.

* This plaster, which is not in general use, is a remarkably nice application, being very adhesive and not tending to induce inflammation of the skin. It is prepared by spreading a strong solution of isinglass, in spirits, upon fine oiled silk, by means of a brush; when about to be applied, it only requires to be wetted with a damp sponge. It is mentioned in Dr. Thompson's work on Inflammation. It was by Mr. Liston that I saw it first used.

VOL. VII.

Dec. 3rd. morning. Improving, fever much abated, p. 98, full and soft, t. clean; no dejection, though the aperient medicine was administered this morning. Abdomen rather more tumid; wound looks favourably, union appears to progress, one suture removed. Injectio enem. oleos 3tia q. q. hor ad effect. post horas sex capiat haust infra prescripti opus sit. R̄. ol. ricini, 3vj. vitel ovi. dimidium, ter et adde gradatm. aq. menth. 3ij. R̄. sennæ sacchari. sing. 3ij, M. 4, P. M. easy, slept some, has had three copious stools, from the enemata without the draft. 9 P. M. goes on well, dej. ij.

Dec. 4th. Free from fever, b. open, lips of wound separated, limb secured in flexed position, and adhesive straps applied.

Dec. 5th. continues to advance as regards his general health; wound suppurating freely and granulating: no union by first intention.

Nothing remarkable occurred in the further progress of the case; the wound was rather slow to heal—an observation which holds good with respect to the generality of our cases in the hospital for some months past. It however filled up, though tediously, with granulations, and was healed completely by the second or third week of January. Patient was discharged recovered, by the first of February.

I have of course not introduced this case as peculiarly suited to illustrate the principles laid down in the preceding paper: nor should I perhaps have considered them sufficiently interesting in themselves to deserve being brought under the notice of the profession. In connexion with a case of some interest, they may, perhaps, by some be considered as worth perusal.

Maryboro, Feb. 14th, 1835.

Aque, Oj;
Acidi sulphurici, ʒ iv.

Used in the treatment of scabies. The affected parts should be fomented two or three times a day with this lotion; at the same time simple baths should be used.

SULPHURATED MINERAL WATERS.

These waters are stimulating, causing an abundant perspiration, a considerable secretion of urine, and act in the same manner as the sulphate of potassa. They are employed both internally and externally in a great number of cases; in scabious eruptions and many other cutaneous affections; in chronic catarrhs, when it is necessary to stimulate, in a gentle manner, the mucous membrane which lines the bronchial and pulmonary cells, in the treatment of scrophulous affections, and of enlargement of the lymphatic glands. They are also recommended in chronic rheumatism, ankylosis, gout, &c.

Water of Baréges.

INTERNALLY.—Three or four glasses a day.

EXTERNALLY.—In baths, lotions, and dashes.

Artificial Water of Baréges. P.

The same doses.

Water of Bonne.

INTERNALLY.—Oj—vj, daily.

EXTERNALLY.—In baths, lotions, and dashes.

Eau de Bonne Artificielle. P.

The same doses.

Water of Cauterets.

INTERNALLY.—Two to six glasses daily, alone, or diluted with milk.

EXTERNALLY.—In baths, lotions, and dashes.

Artificial Water of Cauterets. P.

The same doses.

Water of Aix la Chapelle.

INTERNALLY.—Two to five glasses daily. It is a purgative when a greater quantity is taken.

EXTERNALLY.—In baths, lotions, and dashes.

Artificial Water of Aix la Chapelle. P.
Same doses.

Water of Enghien.

INTERNALLY.—Two to six glasses daily.

EXTERNALLY.—In baths; but when used the temperature should be raised.

Sulphuretted or Sulphurous.

[“ENGLAND.—Codsawood, carbonated; Dudley, carb. cal. and chal.; Llandrindad, chal.; Shapmoor, sal.; Inglewhite, chal. and carb.; Mandley and Shettlewood, sal.; Westwood, chal.; Wirksworth, sal. and chal.; Askerson and Broughton, sal.; Harrowgate and Loansbury, sal.; Normanby, cal.; Rippon, sal. and cal.; Shipton, sal.; Hartlepool, chal. and sal.; Gainsborough, chal. and cal.; and Nottingham, saline.

“SWITZERLAND.—Alvenenan; and in ITALY—Baia, and perhaps Viterbo.”—Treatise on Mineral Waters, 1828. By M. Ryan, M.D., &c., &c. See author's article in London Encyclopedia, Thompson's London Dispensatory, &c. T.]

GUAIAIACUM.

The wood and resin of guaiacum act as general excitents, and as diaphoretics. They are employed with advantage in gout, chronic rheumatism, certain chronic affections of the skin, ancient and obstinate venereal diseases, scrophulous affections, &c. The wood is generally used in syphilis; the resin is preferred in rheumatism, gout, &c. In large doses, this resin becomes a purgative.

Subst. incomp.—Mineral acids, &c.

INTERNALLY.—Wood. *Decoction.*—ʒ ss—ʒ ij, in Oij of water reduced to ij.

Decoction de Gayac composee.

Oj—ij during the day, a glassful at a time.

Decoction de Gayac composee et purgative. P.

ʒ viij—Oj, daily.

Tincture. P. ʒ ss—i, in a potion, or in sudorific drinks.

Resin. Gr. x—i, in pills, or in an emulsion.

Decoction of Guaiacum. H. de. la. Ch.

Coque guaiacum et uram passam simul ad Ov et adjice alia: in dosis Oj—ij quotidie.

[There is a compound decoction of "sweetening woods," used by empirics in Ireland, which often succeeds in scrophula, when the subjects of it are under the adult age, or, in other words, when the disease usually disappears by the use of tonic remedies, and especially after the administration of iodine, or its various preparations. The following is the preparation:—Four ounces of guaiacum wood, of sassafras, of sarsaparilla root sliced, of liquorice root, and of crude antimony. The three first articles are boiled in twenty-four pints of water to one half, and during the process the antimony is inclosed in a piece of new flannel and suspended in the vessel, by being tied to a lath passed over it. The liquid, when reduced to one half, is designated the "strong drink." The ingredients are again boiled in twelve pints of water, and reduced to six—this is called the "weak drink."

The patient is ordered a pint of the first, three times a day; and a pint of the second twice daily. He is directed to live on these drinks and unleavened bread, and his ulcers are dressed daily with an ointment composed of an ʒj ung. resinos. and a ʒi of red precipitate (oxyd. hyd. rub.); or elder ointment alone is employed. He is compelled to continue these remedies and diet, until his ulcers shew a tendency to heal, no matter whether the period is one or three months. I have known many cures effected by this plan, though apparently and obviously different from received medical doctrines, after respectable physicians and surgeons had failed. I knew too persons, who gained a livelihood by curing ("evil") scrophula

by these means: and they revealed the nature of their remedies to me, after having relieved and cured one of chronic dysentery, and the other of sciatica. When the regular medical attendants fail, empirics are applied to, and the above are their remedies. I astonished both the "doctors," by referring to the compound decoction of guaiacum, and also elder ointment, but their reply was, "The articles are not boiled or prepared as I advise." The statements and experiments of Dr. Hancock, in the Transactions of the Medico-Botanical Society of London, 1829, clearly prove that the ebullition of sarsaparilla destroys that article; but I can vouch for the truth of the statements in this parenthesis. Abstract.

An Introductory Lecture on the Studies, Duties, and Qualifications of the Medical Practitioner. Delivered at the Sheffield School of Anatomy and Medicine, by Corden Thompson, M.D., &c. Sheffield. 1834. 8vo. pp. 38.

We ought to have noticed this lecture before, but it has some how or other escaped attention, amid the crowd of pamphlets which pour from the press faster than Goths from the frozen loins of the populous North. Dr. Corden Thompson is a learned and philosophical man, and a distinguished practical physician; his opinions, therefore, on so important a subject as the education and character of the medical practitioner, cannot fail to be read with interest.

The necessity of those preliminary studies which give liberality and expansion to the mind are properly enforced in the following passage:—

“If, gentlemen, there be a profession of which the members ought to receive a pre-eminently liberal and extended education, beyond all question, it is that of physic. There is none, as I have elsewhere insisted, so immediately and intimately connected with the welfare, the comforts, and the happiness of men, during the period of what we call life; none, in the members of which mankind should be able to repose more implicit confidence, nor for whom higher esteem should be entertained. Deprived of health, men do but vegetate, as it were, and breathe a sickly atmosphere of morbid hallucinations; life has no enjoyment, not having that which imparts pleasure to existence. Who that ever laboured under severe bodily ailment knows not the inestimable value of health? Yet, nor power, nor wealth, nor friends, however numerous, can restore this treasure when lost; it is the healing art alone that here proves efficacious. Surely, then, the education of its professors ought to constitute, in a State, an object of no trifling solicitude. It is, in fact, when considered in relation to human suffering that the utility and importance of the healing art become fully apparent. Coeval with the origin of man, the actions of whose frame are liable to aberration from a thousand causes, the practice of physic and surgery has ever been an indispensable requisite, even among the rudest and most barbarous of our species. A still higher interest and importance does it assume in civilized and polished nations where life has greater value. With them, too, luxuriant refinements, injurious habits, and the too often absurd customs and regulations of

society, by multiplying the sources of disease, demand at the same time increased means of succour and obviation. Here it is that ailments appear under more insidious guises and proteiform shapes, and hence, exact greater skill and discernment in detection. There are few circumstances, indeed, in which it is more necessary for a man to possess a cool, collected, and unbiassed judgment, freedom from prejudice, acuteness of perception, and tact in eliciting truth, than at the bedside of a patient. Here, gentlemen, effeminate tenderness, and the officious kindness of well-meaning friends prove equally unavailing. It is not the simplicity of good-natured ignorance which profits on such an occasion, but the discernment of a clear and experienced understanding. The medical character, in fine, ought to embrace, above all things, and in the first place—for the absence of which nothing can compensate—a sound and enlightened judgment.”

The author, admitting the importance of the classical languages to the medical practitioner, insists with much justice on the far higher importance of an accurate knowledge of his native tongue. He makes some animadversions on an oration of Sir Henry Hallford, one of the chief advocates of what may be styled the monkish system of medicine, which, though severe, must be acknowledged to be perfectly just.

“What excuse shall be pleaded for one, who, pretending to a liberal education, and exercising a liberal profession, is nevertheless incapable of writing or using correctly his native language? Examine, Gentlemen, the recent oration of Sir Henry Hallford, President of the Royal College of Physicians. Sir Henry, we are told, is a classical scholar; and truly, if a profusion of Latin scraps in composition entitle a man to be thought so, we must admit the claims of Sir Henry to scholarship. But which, or how many, of the reputed admirable effects of classical learning on the mind does the oration in question evince? Certainly if there be virtue in that sort of writing which is neither one thing nor another; an insipid lifeless compound of English and Latin; a kind of

“party-coloured dress
Of patched and pie-balled languages,”

neither striking in matter, nor forcible in manner; then does Sir Henry's oration possess merit. Power, energy, eloquence, originality it has none; not even the style of a British writer; and oftener than once do we find the author betraying unacquaintance with the English tongue.”

“The first, then,” continues Dr. Thompson, “the most useful, the most essential and indispensable acquisition that a person can make, is a knowledge of his native lan-

guage: and greatly is it to be lamented that this knowledge is so little attended to in the education of medical practitioners. But the English, Greek, and Latin, are not the only languages of which the pupil must acquire a knowledge; he must likewise study the French, the German, and the Italian. The two former of these, indeed, he ought to be thoroughly and familiarly acquainted with; and permit me to say from experience, that I consider their utility, in regard to our profession, infinitely greater than that of the dead languages. They are, in fact, the grand storehouses of modern science; without a knowledge of them, he cannot even keep pace with the advancement of the latter, much less have any pretensions to medical scholarship."

We cannot say that we quite agree with our author as to the relative importance of the ancient and modern languages. English is unquestionably the most important of all languages to an English practitioner, and if he be ignorant of this, he cannot fail to make himself ridiculous, whatever other accomplishments he may possess.

With respect to the modern European languages, although we regard a knowledge of the French, German, and Italian, as quite indispensable to a well informed practitioner, we are, on the whole, disposed to consider that of the Greek and Latin as of at least equal if not greater importance.

A medical man, ignorant of French or German, may read translations of many of the most valuable authors in those languages; but one ignorant of Greek and Latin knows not the etymology, nay, can hardly understand the meaning, of the most familiar terms of his own art. We will not dilate here on the high standing which classical learning gives a man in society; or on that unaccountable power which the study of antiquity possesses, of imbuing the mind with a generous enthusiasm, and casting an imaginative charm around our progress in the severe paths of science. The matter-of-fact men may laugh if they please, but there is a serene pleasure, and a high inspiration, in hearing the great of yore speak, as from the stillness of past time, in their own bold and eloquent accents, while in renewing our academical intimacy with each venerable father of our art, we exclaim,

Accipio agnoscoque libens! ut verba
parentis

Et vocem Anchisæ magni vultumque
recordor!

"Languages, however," continues our author, "whether native or foreign, are but aids or helps; the means by which a knowledge of animate and inanimate objects is attained. The pupil must, further, be initiated in the study of general history, geography, and mathematics. The latter, as Locke has admirably remarked, are to be cultivated not with the view of becoming a mathematician, but of learning the right use of reason; and this use they will inculcate better than all the classics of antiquity.

"From the pure, the pupil will pass to the study of the mixed mathematics; that is to say, those branches of knowledge commonly included under the head of physics, or natural philosophy, namely:—mechanics, hydraulics, optics, acoustics, astronomy, meteorology, galvanism, and electricity. Chemistry is usually not entered on till the studies strictly medical are commenced; and along with it mineralogy and geology are commonly cultivated.

"As a preparatory study, and one of a high order, we ought by no means to overlook mental and moral philosophy.

"After the student, then, has been instructed thoroughly in the theory and use of his own tongue; after he has acquired a tolerable knowledge of the dead and living languages; after he has been taught the elements of mental and moral philosophy, general history, geography, mathematics, and natural philosophy, he will be qualified to enter with advantage on those studies which more immediately appertain to his future vocation. And without these preparatory studies, to a greater or less extent, he will find his future progress difficult, slow, and unsatisfactory. In my opinion, gentlemen, no one ought to enter on professional instruction before the age of eighteen. By that time he may, with tolerable abilities, be sufficiently grounded in the elements of those various branches of knowledge, which he will subsequently cultivate, and become more intimately acquainted with, in proportion as he advances in life, and at the same time as he is extending the boundaries of his scientific acquirements, and pursuing his medical studies.

"Let us now briefly survey the course of instruction which should be followed in respect to the latter. They present a range of the most important and extensive description. To enumerate, for instance, the various particular subjects that necessarily demand attention: anatomy and physiology, human and comparative; anthropology; natural history and botany, chemistry; pharmacy and materia medica; toxicology; dietetics and hygiene; general pathology—which treats of the nature, seat, causes, progress, terminations, symptoms, diagnostics, prognostics, morbid appearances, and principles of treatment, of disease in general; special pathology,—having for its object the nature and treatment of particular diseases, both medical and surgical; clinical medi-

cine and surgery; midwifery; state medicine; medical police and jurisprudence; lastly, bibliography, and the history of medicine."

Many excellent remarks are made on the moral qualifications of the practitioner, among which we would recommend the following to particular attention, since it appears to us that many of our brethren are woefully flat in the region of *self-esteem*—or, to speak plain, that there is a miserably reptile spirit in the profession, as sufficiently evinced by the existing necessity for legislative interference, to lift us out of the mire of degradation, into which, if we had possessed a little more of the real "high moral feeling," we never could have sunk.

"Once more, gentlemen, the medical ought to be a man of the most upright and independent character; a man whose moral courage will not fail him when he has public duties to discharge. There are spirits low, and mean, and grovelling; spirits governed simply by the maxim, 'Put money in thy purse,'—and which for this purpose compass sea and earth; submit to indignity and insult; fawn and flatter; with the most oily tongues, assume the smoothest of faces; hesitate not to renounce their own judgment, nor even to prostitute conscience; are all things, in short, to all men, that by any means they may *secure practice*. Such men have their reward; not, indeed, in the conscious satisfaction of an upright, intrepid, and manly conduct; but in the merited contempt of their professional brethren, and an indwelling sense of degradation.

"He who, on subjects of public interest and importance relative to his profession, possesses not the courage and independence to assert and maintain what he deems just and right; who, through fear of some personal attain, sacrifices a public good; is unworthy of his profession. Well indeed would it be for the latter, did its members exhibit more generally that open manly independence which becomes them, and less of that servile and sycophantish spirit, which, whilst it is derogatory to the character of an honest man, betrays a consciousness of inferiority; of some lack of ability or acquirements; of some want of those general merits which may justly expect and claim success."

We beg, in conclusion, to recommend Dr. Thompson's lecture to our readers, as a judicious and philosophical survey of the education and qualifications of the medical practitioner.

Foreign Medicine.

On the Simultaneous Occurrence and Progress of Diseases of diverse Character, by Dr. Filesius, of Leipsick.

THE cicatrices which eruptive diseases leave behind them, are sometimes themselves the seat of a general irritation, and on the other hand are the parts most liable to respond to any cause of irritation; and ulterior disorders seem to have a special predilection for these points, causing in them, in some circumstances, condylomata, sarcoma, &c.

In his work on Syphilis, John Hunter says, "there is no such thing as a syphilitic itch, or a scorbutic syphilis." Two influences cannot simultaneously predominate in the body, two fevers cannot co-exist in the same individual, nor two local diseases affect one part at one time. The resemblance which endermic forms of syphilis bear to scorbutic affections, has been a source of the erroneous belief that both diseases co-existed in the same point. Both scurvy and syphilis have a tendency to cause eruptions of the skin, when it has any pre-disposing cause in it—an event more frequent in some than other parts of the body. The same person may at once have syphilis and small-pox, that is to say, the syphilis may have invaded the parts which possess the greatest predilection for it, whilst the small-pox seizes on those free from it. But if the two diseases were consequent on fevers, and if each of them was developed nearly at the same time after the fever, it is impossible that the two fevers should have caused eruptions at the same time, even in different parts, for the two fevers that had preceded the eruptions could not exist simultaneously.

What precedes naturally suggests the following questions.—Does not the ill success of inoculation of small-pox, and the inefficiency of its preservative power, proceed from the presence of some other disease at the time of inoculation—a disease which is opposed to the introduction of any other? Is it not owing to this circumstance that those great variations are remarked in the time between the action of the disease upon, and its appearance in the body? For instance, suppose a person to be inoculated and the wound not to inflame until a fortnight afterwards, would not this be owing to the existence of some other disease at the time of inoculation? And might not the cure of certain disorders be explained in this manner—the interruption or stoppage, for instance, of a gleet, on the outbreak of a fever?

I will endeavour to elucidate this doctrine by one of the numerous cases I have observed in my practice. On the 10th of March, I inoculated a child for small-pox, and it was remarked that I made very free scarifications. The 19th, the absorption of the virus seemed to be manifested by a

slight inflammation, redness, and tumefaction of the wounds. The 20th, and 21st, the child had some fever, which, however, was not variolous fever, for the inflammation had made no progress since the 19th. The 22nd, a full eruption appeared, but it was of measles, and the inoculated spots still remained stationary. The 25th, the measly eruption began to disappear, and on the 26th, and 27th, the inoculated points became inflamed; the 28th, this inflammation increased, and a little pus was deposited; the 30th, fever supervened, the variolous pustules went through their usual stages, and ended well.

It may be in like manner observed, that the venereal disease manifests at some more or less distant date from inoculation. May this not depend on a similar cause? Three individuals are exposed to the contagion on the same evening and at the same place. In one a chancre appears in a week; in the second not until a fortnight; whilst in the third, who, being inebriated, had laid down on the damp ground, a violent fever, with inflammatory sore throat, came on the following morning, and it was not until three weeks subsequently, and after the complete cure of those disorders, that he was attacked, not with chancres, but with a clap and bubos.

The following case seems to come under the same category. Charlotte P—, of Leipsick, aged 21, was admitted on the 3rd of July, into the Hospital St. Jacques, having a very full variolous eruption now proceeding to a cure. After being under treatment a whole fortnight, variolous spots rose at some points as high as a quarter of an inch. The previous symptoms of syphilis, and the condylomatous appearance of these pustules, left no doubt as to their syphilitic nature.—*Allgemeine Medicinische Zeitung*.

[This doctrine may be correct in general outline; but it is certain that variolous pustules and vaccine pustules have occurred simultaneously. An instance of this kind may be found at page 537 of the last volume of this Journal].

Extra-Uterine Pregnancy — Passage of the Fœtus by the Rectum.

Professor Francesco Petruni relates the following curious case. Theresa Monaco, 36 years of age, mother of five children, not having menstruated in August 1833, thought she was pregnant, and moreover had all the feelings experienced in her former pregnancies. Qualms, vomiting and pyalism continued for about a month; she then began to have acute pains of the hypogastric region, was agitated, delirious and sleepless. The abdomen was at one time swelled and tense, at other times supple and flat; there was continued pain in the lumbar region. The pains still continuing, doubts began to be entertained of her

pregnancy, the more as six years had elapsed since her last delivery. They were therefore fearful of a chronic metritis, a false pregnancy, or some other uterine disease. Her medical attendants could not agree on their diagnosis; and she merely confined herself to the use of cooling remedies. She passed almost the whole of the month of October with less pain; but towards the end of that month, which was the third of her pregnancy, the pains re-appeared with renewed violence; this relapse was attributed to mental emotions. Fever now did not leave the patient at all, and exacerbated every night: the emaciation became extreme. At the end of the third month, a hard, circumscribed tumour, inclined somewhat to the right side, was observed above the pubis; this increased in size and caused much pain. It was taken for a scrophulous tumour of the right ovary, and was unsuccessfully combated by iodine, hydriodate of potass ointment, cicuta, leeches, &c. In November, movements at first feeble and obscure, and afterwards very manifest, were sufficient to do away with all doubts of the pregnancy. Moreover, the mammae increased, and secreted serum. The intestinal constipation could not be overcome by the strongest purgatives; the transverse colon seemed visibly filled with matter; the whole abdomen was painful: the delirium was constant. Notwithstanding all these circumstances, the pregnancy was still disbelieved; and under the impression that the uterus was filled by accumulated menstrual secretion, and not by a fœtus, ergot of rye was prescribed. This augmented her sufferings and caused a flow of blood from the uterus, a clot, and a small membranous sac, which was taken for a false conception. After this, the tumour, which to this time had been very high, fell down into the pelvis, and the fœtal movements were no longer felt. The costiveness still persisted. The patient had an idea that her rectum was pressed upon and obliterated. She was incessantly teased with a desire to go to the closet. The whole of the 7th month passed in a state which seemed to threaten death momentarily. One day the tenesmus was so extreme that she could not resist the desire to introduce her finger as high as possible into the rectum, in which almost involuntary act, she discovered a hard and pointed body. After a second attempt, she had the courage to withdraw this body, which proved to be the lower jaw of a fœtus several months gone. The patient was then much debilitated, had fever, and the abdomen was hot and tumefied: the hypogastrium was also painful. To the constipation succeeded a flux of gangrenous and foetid matters. The following morning, Dr. Petruni introduced the forefinger of the left hand into the rectum, found the small aperture of amniotic sac, ascertained the present

bones, and, guided by his finger, introduced a polypus forceps: by this means he seized and extracted a bone, at the same time withdrawing his finger, in order to protect the soft parts. He repeated this operation as often as the patient could endure it. After having extracted divers bones of the cranium, and the whole of the vertebral column, he passed emollient injections into the sac. This he renewed on each of the four following days, until all the parts of the foetus were extracted. The treatment consisted of baths and injections into the sac, by means of an elastic tube. The injections were detergent and astringent; the fistulous opening was almost completely obliterated. The author thinks that the amnios will be absorbed. In a fortnight, the patient, who had been considered dying, was restored to her family. Four months have elapsed since that time, and she is in perfect health.—*Il Filiale Sebezio*, Dec. 1834.

New Purgative—Euphorbia Latyris.

According to experiments made by M. Martin Salon, at the Hôpital Beaujon, with this medicine, he has concluded: 1. That the oil prepared by expression, by alcohol or ether, is of easy employment: 2. That none of these preparations have any sensible operation on adults in the dose of two to eight drops: 3. That in a dose of 16 to 24 drops, the two first have decided emeto-cathartic properties, and the third one in the same dose is only purgative: 4. In the dose of two scruples to a drachm, the emeto-cathartic effects become more decided in the two former oils, even sometimes to cause syncope; the oil prepared by ether is equally purgative with that obtained by expression, purges somewhat more than the oil obtained by alcohol, and does not cause syncope, and must be raised to a drachm and a half in dose to produce vomiting also; 5. The maximum dose of any of them is three drachms; 6. They are applicable in icterus, gastric disorders, lead colic, vermination, &c.—*Gazette des Hôpitaux*, Feb. 7, 1835.

CASE OF VACCINATION INTERRUPTED BY MEASLES.

To the Editor of the Original London Medical and Surgical Journal.

[The following case has been received from a worthy Correspondent, Surgeon to the Hospital of a large provincial town.]

In the month of March, 1803, I twice vaccinated Martha, the daughter of John Maule, a farmer, then residing at Rothersthorpe, a village about three miles from this place; and each time the several punctures made in the arm proceeded regularly until the eighth or ninth day, when the areola began to form; but as it each time assumed an irregular or spurious appearance—the edges being serrated, and the colour that of the

damask rose, instead of a bright red, I very much doubted it proving effective, and expressed myself so to the parents, and a desire to vaccinate her again when a favourable opportunity offered. This was complied with, and she was in a few days sent here to school. On the 17th of April following, having a good subject, I vaccinated her again with lymph taken from the arm, making three punctures, all of which had taken, and proceeded regularly as the others had done, until the eighth day from the insertion of the lymph, both inclusive; but upon calling to see her on the morning of Saturday, the 24th of the month, I found her in bed, and very ill with ardent fever, the pulse and other symptoms resembling those that usually precede eruptive diseases; and I was fearful it would prove to be small-pox, as it was prevalent here at that time; some active fever medicine was prescribed, and the next morning an eruption made its appearance, which proved to be measles; during its progress through the system, which was in the regular way, as no untoward symptom appeared, the vaccine areola was suspended in its progress; but as soon as the measles had terminated, it assumed its regular course, and I never saw a better formed areola. I have repeatedly inquired after the subject of this case, and the last time I heard of her, she had been free from every symptom of variolous disease; and since writing the above, I have seen her father, who confirmed what I have stated, as far as he knows; he added, that she had been several years married, and was now residing at Harboro', 17 miles from hence.

This case would afford ample scope to the physiologist that had the inclination or time to indulge in it. My opinion at the time was, that the lymph, the two first times of its insertion in the arm, might have undergone some change, from heat or other causes, it having been conveyed in my pocket to the village, the weather being remarkably warm at the time, though it might have been occasioned by some latent disease in the system, obstructing its diffusion through it, and which I think was the cause in some cases that have since come under my superintendence.

10th Feb. 1835.

By a curious coincidence, we are enabled to refer our correspondent to a similar case, and some observations upon it published in the foreign department of our Journal of this week, under the head of "Simultaneous Occurrence and Progress of Diseases of diverse Character." We had written Dr. Filesius' case out when the above communication reached us.

THE COLLEGE OF SURGEONS—NO INDICATIONS OF REFORM.

Hæc ego non credam Venusinâ digna lucernâ?

Hæc ego non agitem?

Juvenal, Sat. 1. 51.

THE edifice in Lincoln's Inn Fields is fast rising from its temporary ruins, and expanding into ample and majestic proportions. We wish we had good grounds for exclaiming—

"O fortunati quorum jam mœnia surgunt!"

But we have misgivings, and the sight of this building fills us with gloomy imaginings. At one moment we are apprehensive that it will turn out a whited sepulchre: full of dead men's bones we know it to be; and it will assuredly be full of all uncleanness, unless the *twenty-two* wash themselves most diligently from their manifold iniquities.

At another time the structure presents to our eyes the aspect of a fortification; we fear that the *twenty-two* have resolved on not doing the "spontaneous;" that they have determined to show fight, and will, as a necessary consequence, incur annihilation. And is it possible that this monstrous chiro-surgical mollusk thinks it can resist the "pressure from without" by constructing for itself a new shell? If the Council believe that they can escape the scrutiny which is now shedding "intolerable day" into the dark and polluted recesses of our medical corporations, they must be the maddest of mankind; all Anticyra would not purge them of their delusion!

The College of Physicians have found it necessary to adopt the "spontaneous;" but if the College of Physicians have been bad, the College of Surgeons is a thousand times worse.

The former institution has indeed exhibited a melancholy picture of supine ignorance and laziness, of monkish bigotry, and of stolid illiberality; they have however stopped short of crime; they have insulted many, but they have defrauded none, and oppressed few. The College of Surgeons on the other hand have so far outstepped the ordinary limits of corporate iniquity as to have become absolutely felonious.

1. Enormous sums of money paid by the members have been appropriated by the *twenty-two* to "the purposes of the institution;" that is to their own purposes—seeing that they are themselves the only persons who have any control over, or derive any benefit from the said institution.

Further, they for many years secreted the library, which is the property of the *College*, not of the *Council*, and it is our firm belief that they would have secreted it to this day, had they not been compelled to throw it open to the members, by the vigorous attacks of the *Lancet*—the admirable *Lancet*, to which the profession in this country owe an everlasting debt of gratitude.

All this may be called by various soft names. "Call it *conveying*, Hal." Now we will tell the *twenty-two* what we call *stealing*—it is taking possession of other peoples' property without their consent: verily the *twenty-two* have laboured well in their vocation!

2. The Hunterian Museum was given in trust to the *College* for the benefit of the profession and the public. The *twenty-two* have kindly taken all the responsibility on themselves, and have also taken good care to render the museum useless or nearly so to every-body else. Is this breach of trust?

3. They have so framed their own regulations with respect to surgical education, as to restrict the business of teaching to themselves, or those few whom they deign to favour; and they have so influenced the regulations of the great public charities, that nobody

but themselves, and those few whose interests chime in with theirs, are eligible to the situation of surgeon to these charities. Is this conspiracy?

Such are a few of the enormities perpetrated by the *twenty-two*. If their "Transactions" were published, we know of no work that could keep them in countenance but the Newgate Calendar!

But these things must and will have an end. If the delinquents will not yield to reason, they must be dragged to retribution; and what common sense and common decency cannot elicit, the iron hand of public justice will wrest from them. The Council will be taught that in a free country two-and-twenty men are not to lord it despotically over nearly as many thousands; and that if the London College of Surgeons is to continue to exist, the members must have a voice in its proceedings. The plea upon which they have hitherto been excluded is, perhaps, the most impudent piece of sophistry with which oppression ever insulted its victims. The great mass of the members are, it appears, ineligible to the Council, because they practise pharmacy—and it would be most degrading to the Council to have a tradesman in it. Heaven help the infatuated men! the *twenty-two* are themselves tradesmen of the most sordid and disreputable description—dealers in parchment scrolls for which they charge two-and-twenty pounds, well knowing in their hearts that they are not worth a *sous*, and laughing in their sleeves at the flats whom they have *queered*.

If the Council had from the first declared individuals who practise pharmacy ineligible as members of the *College*, they might have done some service to the public, by discountenancing the absurd and pernicious union of a profession and a trade; but a man being once admitted a member, and allowed to continue such, it is no matter whether he is a surgeon and apo-

thecary, or a surgeon and fishmonger; he is *a member of that College*, and has an unquestionable right to a voice in all its proceedings, to a participation in all its privileges and immunities, and a free eligibility to all its offices of honour or emolument. We repeat, that if the College had from the first determined that no individual practising as an apothecary should be admitted as a member at all, such a restriction might possibly have acted beneficially, by preventing medical men from engaging in trade: but mark! the exclusion of apothecaries from the College would have kept the *coffers* empty—a very ugly feature in the statistics of a corporation. If the apothecaries were redolent of jalap, their money was not, and the twenty-two found it a very snug arrangement that others should *pay*, and that they should legislate. If the Council eschewed the trade of the apothecary, why did they not exert themselves to obtain for the members engaged in general practice some more honourable mode of remuneration than the vending of drugs, instead of conniving, as it is well known they did, at the despicable manoeuvres of the *Rhubarbarians* to perpetuate a system so degrading to the profession? Let them answer this if they can, and if not, let them prepare either voluntarily to acknowledge their guilt and amend their ways, or to maintain a hopeless contest against public opinion, and finally to sink under the stern fiat of equal legislation, which has too long slumbered, but is now awake.

—o—

In a letter signed "Paterfamilias" in our last number, the plan of contracting for medical attendance is advocated as preferable to any other mode of remunerating medical men. This plan no doubt has its advantages, and may be conveniently adopted in a few instances. As a general arrangement, however, we think it altogether inapplicable.

The following are some of the evils that would attend it. First, it would too often happen that the doctor would never see his money. Secondly, though the non-medical party might be very well content with the arrangement, when there had been much illness in the house, he would pay the stipend grudgingly when all the family had kept remarkably well for the past year, and it is ten to one would propose an abrogation of the contract for the ensuing year. Thirdly, many people are so unreasonable that the contracting Doctor would be sent for everlastingly, on every frivolous occasion, and would find half his time occupied by a single family. Lastly, the population of large towns is so fluctuating as to render such an arrangement impracticable with reference to the greater part of the community.

We shall probably return to this subject again, but in the meanwhile must repeat our conviction that a legalized system of fees would be the only certain source of just remuneration to the medical practitioner.

Though we do not quite agree with our intelligent correspondent, we shall always be extremely happy to hear from him, and other non-professional friends on such subjects. On all points involving the relations of the profession to the public, the opinions of medical men may often be advantageously modified by those of individuals unconnected with medicine; since every *class* of men have a disposition to view things through some partial medium, which on that very account cannot be the true one.

We are happy to find by the recorded proceedings of a second meeting of the medical gentlemen of Liverpool, that the object of their former assemblage—the establishment of a medical institution—is likely to be attained without any compromise with the grasping

shareholders of the Royal Institution of that town. This is as it should be, and we doubt not that the community at large will cheerfully give their money, and pay respect to the members of the intended association on their present independent ground. We find that our meek friend—the Moses or Melancthon—of the former meeting, attempted to raise objections to the proposed arrangement;—*iterum Crispinus!*

We refer our readers to the account of the second meeting, in our number of this week.

—o—

Hospital Reports.

LONDON UNIVERSITY HOSPITAL.

Case of Erysipelas, with Clinical Remarks, by Mr. Cooper.

MARY PETIT, aged 58, had suffered for some time with an ulcer on the inner angle of the right leg; there was swelling of the foot for some days before she came to the Hospital, and erysipelas had taken place from the foot to the knee when she was admitted; about five weeks ago there was great swelling of the leg, and the knee had a deep red tinge, with two or three dark points in it, indicating that gangrenous suppuration had commenced.

Her skin was dry, pulse quick, secretions diminished, the intellectual faculties quite clear; this was a favourable symptom, for when you find delirium attending erysipelas, the prognosis is unfavourable.

Immediately on her entering, three or four free incisions were made into the fascia through the integuments; there was a considerable discharge of matter, with profuse bleeding.

You make incisions in this stage for two purposes—to let out the matter, and to produce bleeding—these are both attended with benefit. You need not make your incisions more than two and a half, or three inches in length; you will find them quite large enough for the discharge of the matter, and there is less danger than in making them longer; for generally, where incisions are made the whole length of the leg, there is great loss of blood, which is attended with danger, particularly if the patient, like ours, be an old one; there are several cases on record where this practice had been followed, and the results were fatal; you will therefore bear this fact in mind; but, should you in any case find the bleeding too

profuse, your plan will be to tie the vessel, keep the limb elevated, and apply cold.

In our case the incisions were attended with great benefit, for even in twenty-four hours the swelling had considerably decreased; the pulse however was still jerking and ninety-six, the cause of this was, that all the mischief was not removed, there was still a great mass of cellular substance under the skin, keeping up excitement; it is often some days before you can remove this; when it does come away it is generally in pieces of six or eight inches in length. Mr. Chandler found in this case that half a pound came away in one day. When there is suppuration in phlegmonous erysipelas, there is death of the sub-cutaneous cellular membrane; you do not have circumscribed abscess, but diffused suppuration. The leg is much more liable to slough than the arm in erysipelas; the explanation for this given by Duputyren is, that all the great arteries of the leg are situated deep and remote from the skin, the integuments sloughing from want of nutrition. I have long been of this opinion.

We were apprehensive in this case of sloughing of the skin, and had the incisions been delayed a short time longer, there is no doubt, as there was already a few sloughing spots, that it would have become general. Our treatment of this case was at first antiphlogistic, but in four or five days, as there was great exhaustion we gave her stimulants, such as the spirits of ammonia and lavender; we were soon able to discontinue these and to give her wine and quinine in small quantities daily. She is now convalescent. In erysipelas your treatment should always be speedy, if your incisions are delayed the case will prove fatal. If the skin is dead, and you open it, the constitutional irritation will be so great the patient will die, even though young and of a strong constitution. Had this case have come in earlier I should have applied cold to the whole limb. In phlegmonous erysipelas in its early stage, if you wrap the leg up in a cold sedative application, from the ankle to the top of the thigh, it will often prevent effusion into the cellular tissue; but if four or five days have elapsed, and effusion has taken place, make incisions—small ones will do early—but if the case is gone very far they must be larger, in order for the slough to come out. In the early stage of erysipelas also leeches may be applied before the cold; they are frequently of great service, as is also bleeding. Duputyren thought bleeding should be practised before the application of the leeches; this idea is founded on a doctrine not generally followed in this country, that leeches increase the blood in any part to which they are applied, should there be a great quantity in the system. Antimonial medicines, I should mention, are also of use, and I have seen an emetic of infinite service in the early stage of phlegmonous erysipelas.

WESTMINSTER HOSPITAL.

Suicidal Mania—Wounds of the Neck.

GEORGE RICHARDS, aged 30, was admitted February 13th, into the hospital, under the care of Mr. W. B. Lynn.

The patient has a wound of tremendous length in the neck, extending across its summit nearly from one mastoid process to the other, which he this morning inflicted in a paroxysm of suicidal mania. It appears that he has witnessed severe reverses in life, having at one period been a tradesman in respectable circumstances, but that he failed. He possesses a strong frame, and is of a phlethoric habit, and has a wild maniacal expression of countenance. Upon being questioned as to the motives which induced him to commit so rash an act, he replied, that he was seized with a strong impulse, for which he could ascribe no reasons. Upon his admission it was, however, found by the house-surgeon, that the wound was very superficial, not extending much below the skin, and that neither the larynx, trachea, nor any important vessel was in the least degree injured.

The plan of treatment adopted, has been to keep the edges of the wound together by means of simple dressing of adhesive plaister, &c., and a roller applied to the head and chest, in such a manner, as to keep the chin down upon the breast; the head and neck at the same time, being supported by means of pillows, &c. Purgative and diaphoretic remedies have been ordered with the view of keeping down any febrile action that might arise.

23rd.—For the first three or four days after the last report, the patient appeared to be going on very well, but since that period symptoms of cerebral excitement have appeared, which have led to just apprehensions regarding the termination of the case.

On the 20th he was cupped on the temples and eight ounces of blood were removed, and yesterday two blisters were applied in the same situation. Upon removing the blisters this morning it was found, that a rather extensive erythema of the scalp had been excited by their application, which extended over the temples and auricles, and involved also the margins of the wound, which had rapidly advanced towards complete union.

At the present time the countenance is extremely wild and unsettled; the pupils are highly dilated; the mind highly agitated, and evidently labouring under a low form of delirium, very similar to the delirium tremens of drunkards. The pulse is 120, and feeble: the tongue covered with a whitish fur at its circumference, but dry, brown, and fissured in the centre. Teeth covered with an offensive sordes. The gums glazed and dry. The bowels are somewhat relaxed. The inflamed surface has been directed to be dressed with

flour, and he is ordered to take the following pills immediately :

R_x. Calomel gr. viij;
Pulv. antimonial gr. v;
Extract hyoscyami q. s. ft. pil ij, statim
sumendæ.

24th.—It now turns out from the statement of his friends, that he has been a great and habitual drunkard, being in the habit of taking free potations of a mixture of rum and porter. He is evidently worse since yesterday's report. The eyes are suffused with tears, and the vessels of the conjunctiva in a high state of engorgement. The pulse is 140, feeble and tremulous. The tongue more highly furred, and participating in the trembling condition of the features. The wildest delirium is constantly present. Mr. Lynn has ordered him to take the following pills.

R_x. Opii pulv. gr. i;
Pulv. capsici, gr. vj;
Confect. rosæ, q. s. M. ft. pilul
ij, statim sumendæ.

Should the pills be rejected, he has ordered some other form of opiate to be tried. He has also been taking the following mixture, prescribed by the house-surgeon :

R_x. Confect. aromat. 3j;
Ammonia carbon, 3ij;
Misturæ camphoræ, 3 viij. M.
Capt cochlearia duo quartis
horis.

26th.—The delirium grew gradually worse throughout yesterday, and he died this morning at half-past one o'clock.

With the exception of a half dram dose of liquor opii sedativus, and a free allowance of brandy and beef tea, no other remedies were employed.

27th.—Inspection of the body, thirty-six hours after death. Considerable effusion of a sero-sanguinolent quality, was met with in the sub-fascial cellular tissue of the scalp. The sinuses of the dura mater were not thought to be more turgid than is ordinary. There were no traces of hyperæmia in the arachnoid, nor of any of the changes usually consecutive to inflammation. The cephalospinal fluid of Majendie, did not appear to be increased in quantity. The veins of the pia mater were rather more distended, perhaps, than is quite normal, and less doubtful traces of hyperæmia existed in some of the capillary arteries of that membrane. There was not more than a dram of fluid in the ventricles of the brain ; but about half an ounce was met with in the arachnoid sac, at the base of the brain. The substance of the nervous tissue of the cerebrum, cerebellum, and other structures of the encephalon, both as respects its vascularity, consistence, and all other characters, was perfectly healthy.

In the thorax, the heart and lungs, so far as examined, which, however, was not minutely, were found healthy, with the exception of some recent adhesions of the pleura of the right side ; and a rather extensive accu-

mulation of fat about the heart and pericardium.

In dividing the integuments of the abdomen, a very thick stratum of subcutaneous fat was exhibited. The liver was of its natural size, but of a rather paler hue, and more dense texture than ordinary.

The gall bladder was distended with healthy looking bile. The stomach and intestines were distended with gas ; the mucous membrane of the former was somewhat softened and discoloured, and in a few circumscribed spots, presented the puncturated form of redness, more particularly at its lesser curvature. The spleen was extensively and firmly adherent by its peritoneal surface to the opposed surface of the diaphragm ; it was found to be extensively hypertrophied, being about three times the natural size ; its tissue was extremely soft and flabby, being readily broken down by pressure into a substance resembling grumous blood. One of the kidneys which was examined, appeared perfectly healthy.

Chronic Ecthyma.

(Case of Timothy Holland, continued from page 700, Vol. 6.)

Dec. 24th.—He has used the ointment of peroxide of mercury, as directed by Mr. Guthrie, but it proved so highly irritating, that it is found necessary to reduce its strength by one half, and it still produces so much pain that Mr. Guthrie ordered it to be discontinued, and poultices are returned to, with an occasional warm bath at night.

1835, Jan. 2nd.—The sores are gradually healing, and filling up with healthy granulations, some of which are however somewhat too luxuriant. Many of these sores have advanced considerably towards complete cicatrization ; which process has almost uniformly commenced in the centre of the sores, and increasing towards the circumference, has exhibited insular shaped patches nearly covering the sore before uniting with its margin, from which it is separated by annular-shaped fossæ of the granulating ulcer. He merely takes the diaphoretic mixture, and has the sores dressed with simple cerate, and covered with oil-silk. A spot or two of irregular and imperfect phlyzaceous pustules have made their appearance on the scalp.

19th.—The ulcers on the legs have now completely healed, but his face and head have become plentifully covered with the same eruption in smaller and more irregular shaped patches, which have now began to assume the form of grey crusts.

28th.—He complains of severe pains in the head and face, from the eruption, which increases rather than diminishes. The legs and trunk remain quite free. He takes nothing but the diaphoretic mixture, and uses the baths at night.

31st.—Mr. Guthrie ordered him to com-

Murder of a Surgeon by his Patient.

M. PRESTAT, practising at Caylux, had trepanned a patient whose cranium had been fractured a few days before by a blow; a state of mania, which no one, and least of all his unfortunate victim, had perceived, seized the patient, who, having obtained a knife from his imprudent nurse, wounded M. Prestat, when he was at the side of his bed and had his arms raised towards the patient's head to take away the bandages. A wound six inches long was inflicted, extending along the linea alba from the xyphoid cartilage down to the navel: the depth was the same as the length of the knife blade. Every one of the abdominal viscera were more or less wounded. The peritoneum, the mesocolon and its artery, were cut through. The epigastric and mesenteric arteries were also laid open. The unfortunate gentleman lingered eight hours and died, surrounded by his friends. The abdomen was found to be filled with blood. —*Gaz. des Hôspitaux*, Feb. 28.

Early application of Galvanism to Medicine.

THE following grotesque prescription occurs in Scribonius Largus. (De Comp. Medicament, c. 1).
"Pain in the head, however inveterate and intolerable, is immediately removed and permanently cured by the application of a live black torpedo to the part, till the pain ceases and the part is benumbed: when this is perceived to be the case, the application must be discontinued, lest the sensation of the part should be lost. Several torpedos of this kind should be had in readiness, because torpor, which indicates the success of the remedy, sometimes does not occur till two or three fish have been used."

The author recommends the application of these potent fish to the feet in gout. Op. Cit. c. 41. These are curious instances of the employment of galvanism in medicine, long before the existence of that great agent was recognised in science.

BOOK.

The Nature of Cholera Investigated. By John George Finch, M.R. C.S. 8vo. pp. 54: London, 1825. J. and F. Rivington.

CORRESPONDENTS.

- Celcus*—Mr. Wilson's, paper on water-dressings, and the notice of Finch on Cholera, in our next.
- A Student at the Westminster Hospital*—We decline publishing both communications.
- Mr. Langdon*—There are such lectures delivered in summer, and duly recognized by the Royal College of Surgeons and Apothecaries' Hall.
- A Reformer in the College of Physicians*—The College of Physicians only adopt our recommendation in throwing the "Rhabarbarians" overboard. The Medical Reform Bill will be introduced by Mr. Warburton, as soon as the great political drama now being performed is over. In the meantime, the College is reforming itself, in order to save Mr. Warburton the trouble of exposing its illegal and unjust bye-laws.
- Reform in the College of Surgeons*—We understand that the College of Surgeons has determined, so soon as this magnificent Institution is completed, to throw open its splendid library from 10 o'clock in the morning until 10 at night, to the members of the profession at large.

LECTURES

ON THE

INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF
MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE XV.

Arguments Disproving the existence of a Vital Principle, continued—Inadequacy of such Principle to explain the Phenomena of Life.

BUT is not, it may be asked, design, such as can be attributed only to some such vital principle within them, manifested in the heaving and falling of the chest, the contractions of the heart, and the other sensible motions of various parts, as subservient to the several functions of organized beings; and still more in the various molecular actions, whereby, with undeviating accuracy, every particle of every part of the machine is removed and deposited precisely at the time, and in the quantity that is required, not only originally to form these several parts—the eye or ear, for example, those finished examples of exquisitely adapted workmanship—but subsequently to maintain each in a state of integrity, ever varying yet ever the same? Undoubtedly—Design, deep and wonderful: but it is that of the Great First Cause of all things, who has adapted, in every case, the physical causes—the immediate means—to the end to be fulfilled; not that of this miserable means, which acts, and can act only in blind obedience to the laws imposed upon it (a). Nor perhaps are the evidences of design really greater in the motions, sensible or insensible, of the organic, than of the inorganic kingdom of Nature. The revolutions of the planets—the alternations of the seasons, and of day and night—at one time the ascent of the waters into the atmosphere, at another its descent in rain or snow—the motions of the sea, the rivers and the springs—the occasional changes on the surface of the earth itself—all manifest an all-wise and omnipotent design; nor are the molecular actions here also—the aggregation of a crystal or a stalactite, for example, or the feathery condensation of a vapour—less indicative of an end in view in their operation, or of consummate skill in regulating and adapting them. In the latter class of cases, however, we unhesitatingly admit that the design is, not that of the means—of the mere so-called forces of attraction and repulsion—but that of the Great Author of those forces; and why should we doubt that the same is the case in the former also (b)? Nor are even the means employed perhaps less intricate and complicated in the one instance than in the other. When we speak of attraction and repulsion indeed, we seem to be speaking of simple forces, producing certain actions, but we are in fact speaking of the actions themselves—those of attracting and of repelling—the forces being in both cases quite distinct from these actions, and consisting of a property of

(a) "To ascribe," says Dr. Prichard, "to the vital principle such properties, is to invest it, not only with reason and intelligence, but with the wisdom and power of an omniscient Creator, who, if He works by second causes, cannot be conceived to endow them with his proper attributes. Such language is an abuse of words, and contrary to every maxim of philosophy."—(On the Vital

Principle, 1829, p. 123.)

(b) "The whole of the phenomena of matter, whether it be organized or not, are the result of the law of matter, the mere consequents of events immediately antecedent, and have not the least connection with a previous purpose or mental judgment in the beings or things in which they are displayed."—(Useful Knowledge, 1831.)

being attracted or repelled on the one hand, and a power of attracting or repelling on the other: and what more do we contend for with respect to life, than that it is, not a substantial principle operating as a simple force, but a series of actions, resulting from the property of irritability or vitality operated upon by appropriate powers (a)? There is nothing then in reality more singular in the actions of organized beings than in those of inorganic matters, nothing more indicative of design—nothing more obscure—nothing which stands more in need of a substantial principle, or resident entity, to account for it. We may indeed, if we please, in conformity with the views of many philosophers, not only ancient but modern, call these actions of inorganic matters, chemical and mechanical, their life; but then, to be consistent, we must either allow, as the ancients did, a vital principle to inorganic matters in common with organized beings, or we must refuse to the latter a principle of which the former are almost universally regarded in the present day as destitute. It is not contended that we understand the nature of any of these actions—it is not contended that we advance one step towards explaining them by ascribing them to the agents in question: but it is contended that we understand the nature of vital, as well as of either chemical or mechanical action; and that if we are satisfied to attribute the two latter to the agents above specified, as is almost universally done, we cannot, without great inconsistency, refuse to ascribe the former, which are in every respect so analogous to them, to similar agents, instead of to an imaginary substantial principle, of the operation of which there is no more proof or probability in the one case than in the other. Of the immediate nature of physical causes in general we know absolutely nothing, since we are capable of recognizing their existence only by their effects. We know not how or why a certain aggregation of matter, called phosphorus, should be capable, when exposed to certain substances, under favourable circumstances, of exhibiting the phenomena of combustion, or a certain other aggregation of matter, called ivory, should be capable, when struck by a hard substance, of displaying those of sensible motion; but we know that they do so, and we satisfy ourselves, in these instances, with stating that the phosphorus is, *qua* phosphorus, combustible, and the ivory, *qua* ivory, elastic, without ascribing to them any substantial principle of combustion or sensible motion. In like manner we know not how or why a certain aggregation of matter, called organized, should be capable, when acted on by certain appropriate powers, of manifesting the phenomena of life; but we know that it does so—that the more perfect is the organism, the more remarkable are these phenomena, and that any change in the former produces a corresponding change in the latter—and what other proof can we require or possess that organized matter is *qua* organized, irritable or endowed with vitality, and that it is not upon any substantial principle of life that these phenomena depend?

But admitting, it may be said, that quite the lower tribes of organized beings do not display any actions which may not be explained away without conceding to them a substantial vital principle, it is impossible so to dispose of some of the more exalted actions of the higher—actions which are surely in no respect analogous to such as are merely chemical or mechanical. If, however, this sovereign principle can be dispensed with even in those chaotic tribes, from which each kingdom of organized Nature takes its rise—and to which, since they are often with difficulty distinguished, either by their structure or their actions, from mineral substances, it can hardly be considered necessary, even by the most determined substantialist—it will be difficult, if not impossible, to say at what point afterwards, in either of the ascending scales, it can be abruptly introduced; for so insidious are the steps by which we ascend from them to the very highest tribes of organized beings, and so slightly superior the actions of each tribe, as we proceed, to those of the one immediately below it, that we are almost compelled to grant that what was unnecessary to the one can hardly be necessary to the other, and that consequently what we denied to the Fungus and Polype must be denied equally to Man. And with respect to the more exalted actions of the higher tribes of organized beings, such as sensation and thought, these have manifestly no immediate connexion with the existence of a vital principle; since, while on the one hand they are certainly not a necessary consequence of its presumed presence, so on the other they may be easily supposed capable, where they are manifested, of doing without it. Many races of organized beings exhibit no traces whatever of these

(a) Magendie says it is “une étrange erreur” to compare vital action to attraction, because, while the laws of attraction are well known, those of vital action lie totally concealed. But the latter part of the proposition is not quite true; nor would it furnish a fair objection to the comparison, even if it were. The conditions of attraction do not more certainly exist at present than they did before Newton discovered the laws which

these conditions obey, nor do those of vital action less certainly exist at present than they will do when the laws which they obey shall have been fully ascertained. The assumed analogy is between the general conditions of the two, as constituting respectively the proper actions of different forms of matter; not between the specific laws which they severally obey.

actions; and are still alive, and even in those tribes which habitually exercise them, they are always periodically to a greater or less degree suspended, as during sleep, and sometimes totally cease for an almost unlimited time, as in comatose diseases, without prejudice to the life of the being; so that, whatever substantial principle or principles we may find it convenient to introduce in order to explain these more exalted actions, it is obvious that they cannot be identical with the one called life, and that it is not they which

“——— *agitant molem, et magno se corpore miscent.*”

Nor would the admission of one or even of two such additional principles, under the names of sensitive and rational, in any degree imply the existence of that called vital, as the main agent of those baser actions in which alone life, properly so called, consists. On the other hand, many of the arguments tending to disprove the existence of a vital principle serve to render it probable, *a priori*, that that of either of the others is also imaginary; and that, as one specific property, namely irritability or vitality, which is common to organized matter in general, qualifies it, when subjected to appropriate stimuli, to manifest those ruder and less elevated actions which constitute life, so other specific properties peculiar perhaps to certain forms only of such matter may qualify them, when properly acted upon, to display those more delicate and dignified actions in which sensation and thought respectively consist. But into this department of the discussion it is unnecessary and inexpedient to enter at present.

III.—The third head of evidence commonly adduced in favour of the existence of a substantial vital principle, is founded on the presumed incompatibility of the opposite doctrine with a belief in the immortality of the soul. There is in the minds of many persons, not only among the uninformed, but also among the educated, a vague, indefinite kind of impression, that the vital principle, the sensitive principle, the rational principle, and the immortal principle, are all identical; and that he who denies the substantiality of the first, does the same with respect to all the rest. This impression appears to have originated in the ancient complicated absurdity of applying to the three supposed substantial principles of life, of sensation, and of thought, and to the one real principle of immortality, the same name, as soul, spirit, and so forth (*a*); an absurdity which, regulating, as it has done, as well our most philosophical, as our most familiar expressions on these subjects, has not only always influenced, to an incredible extent, the ideas of the vulgar, high as well as low, upon these matters, but introduced into the best parts of the writings of even the

(*a*) An attempt was, indeed, made at a semi-distinction, by Plato, who, while he confounded together the vital, sensitive, and immortal principles under the general name of *ψυχη*, still subdivided this into the *θεωρητικη*, or simply vital, and the *αισθητικη*, or sensitive and immortal, and, at the same time, admitted a distinct rational principle under the name of *Νους* or *Φηνη*; and a similar distinction was affected by the Romans, who, while they called the vital and sensitive principles, collectively, *anima*, distinguished the rational by the name of *animus* or *mens*. Thus Juvenal—

“*Indulsit communis Conditor illis
Tantum animus, nobis animum quoque,*” &c.

Galen again tried an arrangement somewhat different, splitting, as before remarked, the vital *Πνεύματα* into two classes, under the names of proper vital and natural, while he packed, on the contrary, the sensitive and rational together, under the name of animal. None of these proposed distinctions, however, were ever steadily maintained; and, indeed, it was impossible that they should be, thus discordant and irreconcilable as they were. Dr. Barclay, indeed, coolly argues that they were all unfounded; and that the four substances in question, real and supposed, are, in fact, all the same. The immortal principle he every where identi-

fies with the rational, as being responsible for its backslidings; and the rational again must be identical, he infers, on the one hand with the sensitive, and on the other with the vital, for “What,” says he, “can it will or think without feeling, and how can sensation subsist without life?”—(On Life and Organization, 1822, p. 495). Upon such principles as these we might undertake to prove on the one hand that a surety is identical with the man for whom he is bound, and on the other, that the second story of a tenement is identical with the first, and the third with the second, because they cannot respectively subsist independently of each other. Mr. Abernethy had, some time before, contended against confounding perception and intelligence with mere vitality (On Mr. Hunter’s Theory of Life, 1814); and Dr. Pritchard rationally concludes that, at least, the vital principle and the sentient, cogitative, and immortal principle—all which he unfortunately regards as one and the same—“supposing, for a moment, that both really exist, are entirely distinct in their nature and attributes.” (On the Vital Principle, 1829). To a similar effect says Dr. Alison—“Whatever notion we may entertain respecting the existence of a vital principle, it has no connection with our notion respecting the existence of mind, &c.” (Outlines of Physiology, 1831, p. 3.)

greatest philosophers upon the subject of life, so much error and confusion, that we are frequently compelled, while perusing them, to dissent from one-half of those propositions in the remainder of which we most cordially coincide, and close their works in general chagrined and disappointed that what, but for this fatal amalgamation, might have been rendered so clear and perspicuous, should have been presented to us only "through a glass darkly." Upon this subject in general, however, it is sufficient to observe at present, that no arguments adduced against the presumption of the existence of a vital principle—although, in as far as any arguments can establish a negative proposition, apparently conclusive—bear at all, otherwise than analogically, against that of the existence of either a sensitive or rational principle; nor do any arguments adduced against the doctrine which teaches that these exist—strong though they be—tend to shake in the slightest degree, either analogically or otherwise, our faith in, our conviction of, that of the principle of immortality. That the soul is something entirely independent of either a sensitive or rational principle, will be as far as possible demonstrated in future; and that it is independent also of a vital principle must, in the mean time, be obvious to any one who considers for a moment that this latter principle is ascribed indiscriminately to every organized being—a dog, a bird, a reptile, a fish, an insect, a worm, a zoophyte, the lowest fungus—while a soul is imputed to man alone. The differences in the vital phenomena displayed by the most abject tribes of organized beings and by man are only in degree, in this respect *Faba est cognata Pythagoræ*, the principle which we concede to the latter as the cause of these phenomena, must be conceded equally to the former, and if in the one case this principle—

"Redit in nihil quod fuit ante nihil,"

it must do so in the other also; so that to connect Man's hopes of immortality with the admission of a vital principle within him, is so far from favourable, that it is directly opposed to all the best persuasions of religion, natural as well as revealed. But the hopes and expectations of man are founded, or should be founded on a basis infinitely more sure than the supposed existence within him of any such principle—on a basis proper to him, not common to him and the vilest worm or weed—on the suggestions of his reason, and on the strength of his faith; and as so long as these actuate him, every other evidence of the existence of a soul must be superfluous, so, were these once withdrawn, every other evidence must be nugatory.

So much, then, for the alleged testimony in favour of the *existence* of a substantial vital principle. The next subject of inquiry, had this been established, would have been how far it might be regarded as adequate to effect all that has been ascribed to it; but into this question, after the express and unqualified denial of its existence above conveyed, it seems quite superfluous to enter. A successful hypothesis has been compared to a key which fits and opens a lock; but when no part of the structure or motions of a lock are such as to warrant a presumption that there ever was a key, such as has been supposed, made to open it, or that it wants any such key, it seems idle to inquire whether such a key might not be competent, if found, to answer the purpose—we should rather proceed at once to open the lock by such means as its construction and mechanism seem to require, and we have immediately at our command. It may be shortly observed, however, with reference to this question, that it is utterly impossible to conceive any single principle or agent capable of affecting *per se* all, or a thousandth part of what has been imputed to this mysterious offspring, at once of imbecility and boldness, of helplessness and daring—to resist chemical agency—to keep in constant motion the respiratory muscles and heart, as well as to excite all the other muscles of the body, as occasion may require—to generate animal heat and cold—to effect every where the continual absorption and deposition of all kinds of different matters—to digest and assimilate the aliment—to organize the newly-formed germ—to repair wounds, and repel and counteract diseases—as well as to effect innumerable other processes which must require, collectively, not only numerous modifications of any common property, such as we may presume to belong to organized beings, but numerous distinct powers to act on this property thus modified; and which must be attributed, therefore, not to any one self-sufficient substance, however active and however intelligent, but to countless irrational and unconscious forces incessantly at work in every point of the body, in blind but implicit obedience to laws imposed upon them by the Supreme Being, and adopted every where to the end to be fulfilled (a).

(a) It is excellently remarked by Dr. Prichard, "The hypothesis of a vital principle is a weapon, ready to cut any knot, but capable of untying none." (On the Vital Principle, 1829. p. 128.)

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS,

FROM BIRTH TO PUBERTY,

BY DR. RYAN,

Delivered at the Medical School, Westminster Dispensary, Gerrard Street, Soho;

Session 1834-35.

LECTURE XXX.

Congenital Displacement of Organs—Deformities of the Head, Neck (Wry-neck, Stoop)—Superior Extremities, Elbow, Wrist and Fingers—Sternum or Breast-bone (Pigeon or Chicken-breast); of the Inferior Extremities of the Hip, Knee, Ankle, and Feet—Vari, Valgi, and Pes Equinus (Club-feet).

Congenital Displacement of Organs.

GENTLEMEN—The head and soft parts, or organs of the body, may be displaced at the birth of the infant. Every one of the bones may be displaced. The infant may be born with one shoulder higher than the other, in consequence of spinal deformity, with one upper or lower extremity longer than the other, with the head and neck to one side, with the feet turned inwards (vari), or outwards (valgi), claudication or club-feet. The hand or arm may be distorted like the lower limb; or the knee or knees may approximate too closely. Moreover, there may be dislocations or fractures of all the bones. In fine, there may be strabismus or squinting of one or both eyes, and all the soft organs may be displaced or transposed.

Unequal elevation of the Shoulders.—When one shoulder is higher than the other, there is some spinal deformity. Happily for humanity very great attention has been paid of late to spinal deformity; more especially in the orthopedic establishments of continental Europe, and in this country by many eminent and successful practitioners: among whom are Mr. Pott, Mr. Wilson, Dr. Harrison, Sir B. Brodie, Dr. Jarrold, Mr. Ward, Mr. Copeland, Mr. Shaw, Dr. Dod, Mr. Beale, Mr. Stafford, &c. &c. It is unfortunate that a great diversity of opinion as to the cause and treatment of spinal curvature exists amongst these authors; some strenuously recommending the recumbent position, others opposing it; more advising traction after the manner of Ambrose Paré. Dr. Harrison is the strongest advocate of the last practice; and, it is but justice to declare, that his method has succeeded when all others have failed. He has adduced the results of several cases in his work on Spinal Diseases, which were favourable, after some of our ablest surgeons had declared the cases to be hopeless. He has adduced several successful cases, which were declared hopeless, in a paper addressed to Sir B. C. Brodie,

published in Dr. Ryan's London Medical and Surgical Journ. vol. 6, 1835.

The vast importance of spinal diseases, is my apology to the reader for this long digression. If it be a practical man, he will at once receive it. If he be not, future experience will convince him of its value. If he will take the trouble to analyze the immense number of head, chest, and abdominal derangements that daily present themselves to those engaged in extensive practice, which are most absurdly and called nervous, hysterical, or hypochondriacal disorders, but which, in reality, depend upon spinal irritation, incipient or established deformity in the vertebral column (or spine), he will at once admit the inestimable value of the preceding observations. If he be superficially informed in medical science, or a sceptic, I beg him to peruse the works whose titles are inserted at the bottom of this page*.

In hospital and dispensary practice we daily see a vast number of women, young and old, from the age of puberty to senescence, who suffer most calamitously from spinal irritation or deformity. There are, perhaps, no patients so numerous, so nervous, so hysterical, so hypochondriacal, or so unfit for performing domestic or social duties. There is scarcely a female of tender or ma-

ture age in the middle and upper classes of society, who is not a sufferer from spinal irritation or deformity, with the innumerable disorders and derangements of all the functions of the body, of the brain and nervous system, of the circulation, respiration, digestive, muscular, secretory, and other functions (Teall, Addison, Tate, Beale, &c.) The cause of this will be explained hereafter, in the article of spinal and other deformities; but enough has been stated to convince you of the great importance of rectifying deformities of the head, shoulders, and limbs in infants, which depend, in most cases, on deformities of the spine. These we shall now describe.

To return, then, to the elevation of one shoulder more than the other, I have to state, that an infant born with this deformity has more or less spinal curvature, and runs the risk of being deformed for life, and of being a great sufferer from a thousand and one disorders, from painful sensations in every part of the body, head, chest, abdomen, and extremities, unless proper means be taken to correct his defects. The proper time for remedying all infantile deformities is during lactation or suckling, as the bones are unossified, and easily reduced to their proper position, and as the breast is the most powerful sedative or tranquilizer of the infant. The application of appropriate splints and bandages is indispensable. The various orthopedic means ought to be employed, the infant well nourished, and the most scrupulous attention bestowed on its physical education or management. Its diet, sleep, rest, exposure or exercise in the open air, cleanliness, &c., should be regulated according to the principles laid down in the preceding part of the lectures. It never should be thwarted or teased, however irritable or peevish, as its disease is the cause of its bad temper. Adults and parents, when the subjects of spinal irritation or deformity, however slight, are not, and cannot be the most even tempered. Neither can children, who are adults in miniature. It is essential to employ those amusements and exercises which would throw the unaffected side of the body into motion, as these would strengthen the muscles on that side, and tend to bring the spine and body into the erect position. Reposing on the affected side contributes to this result. Various gymnastic exercises are essential to the cure, and all means should be persevered in to the last. It has fallen under my observation, that many cases of deformed children, especially females, before the age of puberty (fourteen or sixteen years), in this climate, and even a year or two afterwards, were finally cured by persevering in the use of remedies. The same principles apply when one arm is longer than the other in consequence of the curvature of the spine; but not when this deformity is the result of embryonary or original malformation.

Obliquity of the Head and Neck.—This deformity cannot exist unless there be disordered action of the muscles of the neck, or deformity of its bones (cervical vertebræ). This distortion should be treated like the last, while the infant is at the breast, and as soon as possible. Splints, bandages, collars, and frictions on the opposite side of the neck, are the chief remedies. Stimulating liniments and embrocations are the best. When the infant begins to distinguish surrounding objects, its attention should be directed to the sound or unaffected side of the neck. The same principle may be acted on in applying it to the breast. Its cot or cradle ought to be so placed, that in viewing objects it may turn to the unaffected side, which will exercise the muscles on that side, and contribute to their strength, and its recovery.

Wry-Neck—Stoop.—There are other distortions of the cervical vertebræ, causing wry-neck and a stoop, which are to be treated upon the above principles. The causes of these deformities are, holding the head to one side, and the attitude of the infant, when always carried on one arm by the nurse, or lying constantly on one side in bed, burns, wounds, abscesses, &c. A properly-constructed instrument will extend the affected muscles; and when the disease is caused by the cicatrices or scars consequent to burns, the operation proposed by Mr. Earle ought to be adopted.

Malformation and shortening of the Upper Extremity—Arm, Elbow, Wrist, and Finger Joints.—This disease, which is seen occasionally, admits of no remedy. It is ascribed to an arrest of embryonary development, which as yet remains inexplicable. Deformities, distortions, or contractions of the joints of the superior extremity are very rare, unless in cases of rickets.

Contraction of the Elbow Joint—is sometimes caused in new-born infants by a morbid condition of the biceps muscle. The best remedies are extension by splints or other instruments, such as that proposed by Mr. Amesbury for stiff elbow joint, which has a screw which will overcome any muscular resistance, if used with proper caution, prudence, and perseverance. Shampooing, friction with iodine, and vapour baths, are also to be employed as auxiliaries. When the disease is caused by ankylosis or ossification of the joint, a cure can scarcely be expected; but even in this case I should use iodine and steady extension. I have known ankylosis of the ankle joint cured by this method in a case at St. John's Hospital, which was witnessed by my then colleagues, Dr. Negrie, Mr. Jenkins, and Mr. Nettlefold, and for which amputation was proposed at St. Bartholomew's Hospital.

Contractions of the Wrists and Fingers.—When these are congenital, they are remediable deformities; if of the ankle, foot, and toes, by splints and bandages. When they

are caused by the cicatrices or scars which follow burns, Mr. Earle has succeeded in curing them by excising the scars and applying splints. (*Medico-chir. Trans.*, vol. 7). The sooner the operation is performed the better. The late Baron Dupuytren related several successful cases.

Mechanics, labourers, washerwomen, and others, are subject to contraction of the ring and little fingers; and these are often removed by improving the general health and applying the antimonial ointment on the side of the neck over the origins of the brachial nerves.

Deformities of the Inferior Extremities.—The lower limbs are liable to various deformities: one extremity may be longer than the other, one shortened, wasted, and contracted: and in such cases there will be curvature of the spine in the infant, or spinal irritation in the adult, giving rise to facial and other neuralgia. The same disorders often supervene, when an adult has the lower extremity amputated at the hip joint. The whole weight of the body will rest upon the remaining limb, the spine must be twisted, and neuralgia of the face, chest, abdomen, and limbs, may follow.

When one limb is shorter than the other at birth, or is perceived when the infant walks, artificial means should be employed in all cases in which they are admissible. If the shortening is trifling, it may be remedied in some measure by a high-heeled shoe, by an iron patten or clog, or some such contrivance.

Inequality of the inferior extremities may be caused in children by paralysis, or disease of the hip, knee, or ankle joints. In the first case, the limb is observed to waste at the period of dentition or ablactation. The means of cure are to improve the digestion and general health by gentle aperients, chalk with mercury combined with rhubarb, &c., quinine, preparations of iron, friction, cold sea-bathing, nutritious aliment, warm clothing, exercise in the open air; in fact, all restorative means employed in rachitism, scrophula, and during the convalescence after acute diseases, such as fevers, scarlatina, small-pox, measles, inflammation of the lungs, &c.

Deformities from Malformation of the Hip Joint.—Congenital malformations of the thigh bones and sockets (acetubala) are occasionally observed. Deville, Crele, Palleta, and Dupuytren, have described such cases. The first three mentioned relate examples, in which one or both acetubala were filled up, and the head of the thigh bone rested on the hip or vicinal fossa. In such cases the limb was shortened. Even the head and neck of the femur (thigh-bone) has been absent (*Palleta*). Baron Dupuytren has given an admirable account of such cases (*Repertoire Gen. d'Anatomie*, tom. 2), and also M. Cruveilhier (*Anat. Pathol.*) Mr. Beale has abridged both descriptions (*Trea-*

tise on Deformities, &c. 1830), a work which ought to be in the possession of every medical practitioner, and to which I beg to refer my hearers. This deformity impedes locomotion, and tends to induce spinal curvature. It produces the same effects as dislocation of the thigh-bone. (See Sir Astley Cooper's work on *Dislocations*; *Cooper's Surgical Dictionary, &c.*) The disease may be readily mistaken for scrophulous inflammation of the hip joint. Baron Dupuytren states, that he met with persons affected with this malformation, who had been confined to the horizontal position for several years, and had been unnecessarily treated with repeated leechings, blisters, moxas, cauteries, &c., without any advantage. The absence of fever, pain, inflammation, fluctuation, and constitutional disturbance, will readily enable us to form an accurate diagnosis. Dupuytren attributes such malformations to intra-uterine luxation caused by the movements of the foetus in the womb; and Geoffroy St. Hilaire, with much more reason in my opinion, to some accident which has deranged the order of embryonic development. The former has invented a bandage for such malformations, from which a few have derived benefit.

Malpositions of the acetabula, caused by rickets, may also induce lameness on one or both sides; but the history of the case will enable us to diagnose correctly.

Delpech describes cases of lameness caused by shortening of the psoas magnus, iliacus internus, flexors and extensors of the thigh-bone; to remedy which, he advises continuous extension; and in elongating shortened muscles their size increases.

Deformities and Contractions of the Knee Joint.—These are of two kinds—the knees are turned inwards or outwards; but the former are the most common. Mr. Beale, in his work on Deformities, gives a minute account of the anatomy and pathology of these affections, which my limits do not allow me to transcribe; but his account of the treatment deserves attention.

Deformities and Contractions of the Knee and Ankle.—These diseases are sometimes, though rarely, congenital. When they occur at birth they are easily cured, by placing the joints in their natural position, and retaining them so by appropriate splints and bandages (*Venel, D'Yvernois, &c.*) Our chief object is to overcome the rigidity of the muscles and ligaments. In what is called white swelling, it is important to prevent the limbs from uniting in an angular direction, and this can be effected by the means already mentioned. It is old-fashioned surgery to allow the knee to form an angle nearly acute with the thigh; and, according to Sir Astley Cooper, it is much better to cause the inferior extremity to be straight. (See his *Lectures on Surgery*, 1824.) It is remarkable what a degree of rashness is employed in these cases. I knew a young

lady, the daughter of an eminent physician, whose leg united in an angular form with the thigh. The best advice was previously had, and the only remedy proposed was amputation, to which the father would not consent. A curved joint finally formed; and, as the sufferer was a beautiful girl, her condition excited great sympathy and commiseration. She had also lost her father. An empiric boldly proposed to cure her. She consented. He placed her on a sofa, and with force extended the diseased limb. He then applied splints and bandages, and kept these constantly wet with vinegar and water. In six weeks the limb was straight, with an anchylosed joint. Few educated surgeons would attempt such an operation, because ninety-nine out of a hundred patients would be destroyed by it. In cases of white swelling of the knee and other joints, great success follows the use of the different preparations of iodine, employed both internally and externally. The proto-ioduret of mercury*, the deuto-ioduret of mercury†, the ioduret of lead‡, the hydriodate of potass§, the hydriodate of iron||, and, in the worst cases, the ioduret of arsenic¶, might be employed with advantage. As these remedies are not, as yet, in our British pharmacopœias (for we are proverbially slow in adopting new medicines). I therefore deem it advisable and necessary to state their doses. I may also mention another new remedy in ulceration of the cartilages of the joints—hip, knee, ankle, wrist—diseases intimately connected with white swelling, is mercury, which was successfully employed by Dr. O'Beirne, of Dublin, and the results of his experience attested by Dr. M'Dowel, Mr. Carmichael, and Mr. Roney. (*Dublin Med.*

* Proto-ioduret of mercury—dose for an adult, gr. one-eighth to one-half, in pills; dose to be proportioned according to the age and strength of children. Ointments, ℞ i—ij, iij, iv, to ℥ ij of prepared lard.

† Deuto-ioduret of mercury—dose for an adult, gr. one-sixteenth to one-half in alcoholic solution or pills—ointment, ℞ i—℥ jss.

‡ Ioduret of lead—gr. i—x; according to M. Bailly, gr. i—xxx. I have found this preparation extremely successful in scrophula, and in syphilis complicated with it.

§ Hydriodate of potass, gr. x—xv, in distilled water, ter in die; ointment, ℥ ss—ids—℥ j); sometimes with tinc, opii. ℥ j.

|| Hydriodate of iron. Internally as a tonic, gr. ij—x rapidly increased to xx.

¶ Ioduret of arsenic, in cases of adults generally; when scrophulous persons have syphilitic disease of the bones, and in necrosis, it possesses the properties of its component parts, is extremely poisonous, and has hitherto been used externally; ointment, gr. iij—℥ j. It would be wrong to give to children, unless every other remedy had failed, and then in extremely minute, infinitesimal, or homœopathic doses.

Journ. 1834, vol. 5; *Lond. Med. and Surg. Journ.* 1834, vol. 6).

Deformities of the Feet—Club-foot, &c.—The deformities of the feet, as when turned inwards (vari), or outwards (valgi), or when the infant walks on its toes (pes equinus), generally admit of complete cure. Numerous infants were treated by me successfully. The bones and ligaments in such cases are easily reduced to their natural position by proper bandages and splints: but a cure is extremely difficult when deformities occur after birth. I am borne out in this opinion by Mr. Beale, a late and excellent writer on Deformities, Distortions, and Contractions of the Limbs, Joints and Spine, 1831, who thus expresses himself—"There is no case of club-foot, however bad, which may not be remedied, and but few which cannot be altogether cured, by proper means employed immediately after birth. The earlier the period when these malformations are treated, the more simple are the means necessary for their removal; and, by great perseverance, these deformities may often be cured before the period arrives when the child should walk. It is a disgrace to civilized society, in the present advanced state of science, to witness the cases of distorted feet which present themselves in this town; for there are not ten cases in a hundred that might not have been during infancy entirely cured, and in the rest the deformity might have been considerably diminished. I never pass a day without observing adults with various degrees of club-foot, from a slight inflection of one foot to those cases of great deformity, where both feet are contracted and turned inwards; every one of which might have been removed, if properly treated in the early part of life. They may be alleviated at any time before the growth of the body has ceased; but, of course, the longer the treatment is delayed, the more difficult it becomes: after the age of 10 or 12, a perfect cure rarely takes place, and the earlier means are adopted for relief the better."

There are three species of club-foot; when the foot is turned inwards (vari), outwards (valgi), and when the infant or adult walks on the toes, or in common language, pointed toe (pes equinus, horse-hoof.) In all these deformities there is not a complete dislocation, as would appear on a first view of the affected limb. There is not a tibio-calcaneo (dislocation of the leg and foot), but it arises from a torsion of the bones of the foot, the os calcis, the tarsus and toes. The result is a displacement of the sole and instep of the foot, a shortening and tension of the flexors of the leg, an apparent curvature of the leg and knee; and the effect will be an unsteady gait. Because the weight of the body is not supported on a sufficient base. It is important to state that the bones of the whole body are imperfectly ossified at birth; are partially soft and easily

placed in their natural position. This fact justifies the conclusion that club-foot is easily cured, when proper means are employed a few days after the birth of the infant.

The causes of these deformities are unknown. They are attributed to the restrained position of the infant in the maternal womb, when the amniotic fluid that surrounds it is small in quantity, to an arrest of development (Breschet, Chaussier, Cruveilhier), to feebleness or paralysis of the abductor muscles (Beclard), and they also accompany spina bifida. It is true that the infant may not move during the whole period of pregnancy, or at least is not felt to move by the parent; nevertheless, it is not only born alive, but perfect in all parts. Deformities often occur after birth, and are ascribed to the nurse's holding the infant too much on one arm, and consequently, inclining one lower extremity inwards. This constrained position of the infant may possibly induce disease; but it cannot, in my opinion, be a very frequent cause, as nine in ten mothers and nurses, who are right-handed, hold the infant on the right arm; and yet deformity of the lower limbs is comparatively of rare occurrence during infancy, unless errors in diet, clothing, cleanliness, exposure to the air, exercise, prevail. All debilitating causes of this kind, all acute diseases, teething, whooping cough, inflammations in the head, chest, abdomen and limbs, eruptive fevers, scarlatina, small-pox, measles, &c. &c., predispose young infants to deformities in the spine and limbs. The reason is obvious. The muscular power or strength is diminished, and the muscles of the lower limbs are unable to sustain or bear the weight of the body, and the bones being soft, readily bend, or to use a popular phrase, "grow out." It is generally observed that deformities commence about the time of weaning, when improper food is usually given, the infant being peevish on account of the loss of the breast milk, and soon getting into a delicate state of health. But the disease may commence earlier than the period of ablation or weaning, especially in infants of the poor, who are mismanaged from the moment of birth, as regards diet, clothing, cleanliness, exposure to a pure air, &c. Under all these, and many other debilitating causes, the digestion is impaired, a sufficient quantity of nourishment is not extracted from the food by the enfeebled stomach, a sufficient addition of nutriment (chyle) is conveyed to the heart and not added to the blood; a deteriorated and deficient quantity of blood is circulated to the different organs, and these being deprived of a sufficient supply, as in health, become enfeebled, cannot perform their functions or uses properly, and delicacy or disease in some one of them, according to the predisposition of the individual, is the consequence. In fact, the digestion,

circulation, or innervation (power of the brain and spinal marrow) being defective, or deranged, must derange every organ in the body, the muscles amongst the rest, and thence those of the lower limbs and trunk are rendered incapable of supporting the weight of the body, and deformities of the limbs, spine, growing out of the shoulder or back, is a frequent result. It will appear by a reference to the remarks on the physical education of infants, that few of them escape from irritation in the stomach and bowels, in consequence of the administration of improper food and drink to them. If these parts be disordered, they derange the respiration, the brain, and all parts—a fact proved by the innumerable complaints and disorders in almost all parts of the body, by persons labouring under indigestion, hypochondriasis, nervousness. The same train of disorders exist in children. But supposing the digestion to be good, which is seldom the case, unless the infant thrives, the nutriment or chyle cannot be changed into vivifying blood, unless the process for that purpose (respiration) be healthful. Exposure to a pure air is necessary for the proper performance of this function. But in large crowded cities and towns, the children of the poor and labouring classes seldom enjoy the essential advantage of good air, or other hygienic means; and the result is, that delicacy and disease is most common amongst them. But admitting the digestion and respiration to be natural, health cannot be preserved unless exercise be taken in the open air, especially on foot. This circulates the blood to every part, by increasing the action of the heart and arteries: strengthens every part; and those who live in rural districts are proverbially the healthiest of the population.

When infants are enfeebled by mismanagement or disease, from the first to the fourth or fifth year, they are very liable to deformities of the spine and limbs. The enfeebled muscles are not able to support the trunk; and the spine and lower limbs become deformed. This is of frequent occurrence from the twelfth to the eighteenth month, or second year. The infant loses the power of its limbs, or, to use a common phrase, "gets off its legs." About the period of weaning or of teething, or after any severe disease, the joints of the ankles, wrists, knees, hips, and spine, are weakened, and cease to perform their functions. The bones bend, and deformity is the consequence. It is, however, consoling to know, that children who become deformed after birth, from the age of one to five years, almost invariably recover and become straight, if the general health be improved, and the treatment be rational, even without the use of mechanical contrivances. The reason of this favourable result is clear to the educated practitioner. He knows that the bones and ligaments which unite them, are but partially deve-

loped in the first year of infancy; and if the muscles be strengthened by proper diet, healthful respiration, exercise in the open air, cold bathing, tonics, and other invigorating means, they will speedily restore the deformed bones to their natural situation, and the body to the straight and erect position. This fact is attested by every modern writer on deformities, and on rachitism or rickets. (Mason Good, S. Cooper, Harrison, Beale, Scarpa, Dubois, Delpech, &c. &c.) I have seen it proved in a vast number of instances. Congenital deformities which occur before birth, are, on the contrary, never removed without mechanical aid, but are generally cured by this means. The explanation of this apparent contradiction is simple. The infantile constitution at birth, is much more frail and feeble, than at the age of a year or two; and requires infinitely more care and attention. At birth, the infant is almost deprived of exercise, the muscles are slightly exerted by dandling, holding in the arms, and other positions: they are already so weak as to admit of deformity; and therefore we must assist nature by mechanical contrivances, and support the bones in their proper situations, which the muscles and ligaments cannot do by themselves.

The indication of cure is to reduce the deformed foot to its proper position, and secure it with a bandage properly applied. The younger the infant the easier to cure its deformities. Great care should be taken not to cause undue pressure. The bandage ought to be applied, first round the toes, and carried on towards the leg; and strips of strong paste-board, or their splints carefully enveloped in lint, may be placed, if necessary, on the sides or sole of the foot. Lastly, the folds of the bandage should be stitched together; and it should be removed and another applied every twenty-four hours. I have cured several new-born infants by this simple plan of treatment, in the course of six or eight weeks, but others required a longer period. The difference of constitution, and the solidity of the bones, vary very considerably in infants; and, consequently, the period of cure cannot be alike in all cases.

In cases of varus, or turning of the foot inwards, the chief indications of treatment are to restore the foot to its proper position, and to retain it so. Scarpa devised an instrument for this purpose, and Colles another. The first is illustrated by a plate in Mr. Beale's work on Deformities, to which I am much indebted for many facts relating to this class of diseases, and that of Dr. Colles in the Dublin Hospital Reports, vol. i.

As a general rule, neither bandages nor mechanical contrivances should be allowed to cause pain, nor to impede walking, if used when the infant can attempt this kind of locomotion. Manual frictions of the muscles of the affected limb should be made morning and evening for at least an hour after bandages or instruments are removed, as

these strengthen the muscles. When the foot is restored to the natural position, a boot should be worn, with the outer side of the sole thicker than the inner, so as to incline the foot outwards.

In valgi, or turning of the foot outwards, the instrument must be reversed.

In the *pes equinus* or pointed, the object is to reduce the foot and toes to their ordinary positions: and, perhaps, the best apparatus for this purpose is that of Mr. Amesbury.

In treating these deformities, it is imperiously necessary for the practitioner to possess an accurate knowledge of the anatomy and natural positions of the affected parts, or it will be impossible for him to succeed in removing their derangement.

There is much more difficulty in removing the *pes equinus*. This generally affects one limb; the individual walks on the toes; there is a permanent extension of the foot, and it is on the heads of the metatarsal bones that the person stands or walks. Some have supposed that this deformity was caused by a rigidity and shortening of the extensor muscles; to remedy which, Delpech proposed to incise the tendo Achillis. It appears to me, that this operation would only be justifiable when all other means had failed; and even then, I very much doubt its propriety.

It is a pleasing reflection to think on, that though infants are subject to numerous deformities, we seldom of late years observe an equal proportion in adults. It is true, we now and then see instances of in-knee, baker's-knee, and bandy legs; but these are comparatively rare at present. Mr. Beale observes, "I am acquainted with several children, more or less affected with deformity of the legs, in whom I could attribute them to no other cause than that of being instructed to stand and walk too early; their health has been uniformly good. Nutrition has apparently gone on as it should do, and yet about the age of twelve or eighteen months, their legs have begun to show signs of weakness and deformity." He goes on to state that children should be allowed to stand and walk, when they shew an inclination.

Recent deformities of the knee are said to be curable by some continental writers, by proper mechanical instruments (Venel and D'Yvernois.) They devote much more attention to orthopedic medicine in France, than we do in this country. Justice obliges me to add, that we have not, as yet, a single Institution in the metropolis appropriated to this class of diseases. She also reminds me, that Dr. Harrison, whose name has been honourably mentioned in these pages, has lately given the sum of £1000 towards the funds of such an establishment. Our munificently endowed hospitals have done nothing for the removal of spinal and other deformities—not even Guy's or St. Bartholomew's Hospital, with immense funds, notwithstanding the Abernethies, Astley Coopers, &c., once connected with them.

It is a singular fact, that there is no work in the English language excepting Mr. Beales', which treats so favourably of human deformities of the bones. There are many excellent treatises on particular varieties of spinal distortion, but these are silent on deformities of the limbs. Even our works on surgery treat of these maladies very superficially. Foreign writers have, on the contrary, devoted great attention to this class of diseases, and have employed a vast number of well constructed mechanical contrivances for the removal of human deformities.— These may be seen and examined in their numerous orthopedic establishments. This branch of surgery has been hitherto unaccountably neglected in this kingdom, and generally consigned to mechanics, though human deformities are of very frequent occurrence. They have been ascribed to the progress of arts and civilization, as they seldom occurred in remote ages, and are only met with among the inferior animals when domesticated. But they are extremely common in the human species. Perhaps the proportion of half the female children under the age of puberty suffer from more or less contortions of the spine, and are rendered nervous and enfeebled during life. The frequency of spinal and other deformities is to be attributed to errors in physical education, and to the indefensible custom of confining girls to a restrained position for several hours a day. Their brothers, who are not so constrained, play and romp about; they exercise their muscles, and for the reasons already stated, are sound and healthful, and scarcely ever suffer from deformities of the bones. I have fully described the cause of deformities in girls in my remarks on scholastic discipline and education. I may, however, make one observation on the subject in this place, and it is this: that it is impossible for any being (young or old) to retain one position for twenty minutes at a time, without fatiguing and enfeebling the muscles, and rendering them incapable of keeping their bones in their proper places. Let any one try the experiment of standing or sitting in one position for a quarter of an hour, and he must admit the truth of my statement. At our next meeting, I shall describe spinal deformities, and conclude this subject of displacements of bone.

M. VIREY ON THE GENERATION OF
ANIMALS AND PLANTS.

(Continued from Vol. 6, p. 628.)

—

*On the different Modes of Reproduction of or-
ganized Beings compared to Man.*

If there was on earth no other mark of divine wisdom than that which is apparent in the sexual organs, this would be sufficient to prove the existence of an intelligent Being. How is it possible to mistake the relations so intimate and so perfect between the sexes?

Who does not perceive that the objects for which they are designed are most wisely combined? The disposition relative to these organs is not only admirable, but even their influence on the living body, and especially on the whole economy of the individual, is adapted with a sublime foresight. This concordance of individuals, this tendency to reproduction, this community of sentiments, this reciprocal concourse of actions, can they be the work of chance? This perpetuity of beings, this immutability of each species, which do not confound themselves with other beings, do these depend upon chance and an indefinite aim?

The sympathies between the sexes incline all to love, though they disguise it under a thousand forms. Females, in general, are the site of the species: they contain the essential principle of it; every female individual is exclusively formed for generation. Her organs are the root and foundation of all her structure. The principle of her life resides entirely in these organs, and greatly influences the rest of the living economy. Males are more erratic in generation; their sex is not the most important part of them; but in the female it is, on the contrary, her very soul, if I may use the expression. Males do not love, to speak correctly, their females, but the new being of which these are the depositories; for they have no more love when they no longer reproduce. Thus fishes only love the eggs of their females, and follow them for this sole object. Among animals the female is no longer sought for by the male after she has conceived. Individuals who have been subjected to castration, inspire contempt, and not love. This sentiment, then, has not power or vivacity, except so far as it serves to the production of the species; and it has not for its object engendering individuals, whilst they may be indifferent to each other, without the desire to reproduce each other.

Nevertheless, the generative organs have their periods of activity and repose. Almost all vegetables produce flowers and fruits once a-year; most animals couple but once a-year; sometimes many species engender oftener; and others more rarely. In plants, the organs of generation fall with the seeds and fruits, and are renewed every year. In animals, the same sexual organs serve during the whole course of their life; but these have periods of development and excitation which we call the *rut* or *heat*, after which they wither, diminish, and almost become obliterated, until a new season of love awakens them from their torpid condition, and recalls them to a momentary existence. The activity of the life of the species, or of the generative faculty, is intermittent or periodic. In the human species, and in animals which equally consume abundant and nutritious food, the generative faculty is perpetual, and their sexual organs remain in a condition more or less fitted for

the act of propagation ; nevertheless, we here remark the periodical impulse of the life of the species. Thus, the woman is subject to a periodical evacuation once a month, and so, according to some, are a few of the monkey tribe, but in an indetermined or irregular manner*. The females of quadrupeds have their periods of amorous impulse, at their period of *rut* or *heat*. There is something analogous in birds whose sexual organs have become excited, hot, red, and dilated, and are in a kind of erection until the act of conception is accomplished. Reptiles, fishes, insects, and worms, have a similar excitement or orgasm at fixed periods. In fine, plants develope their buds, expand their flowers, display their petals, elevate their stamens and pistils, until fecundation is effected.

Not only does there exist a time of amorous effervescence and of rut in all living nature, but it is principally at the moment of generation that the sexual organs are excited to the highest degree of sensibility. All the powers of the soul then contract themselves in these organs, which are in a violent state of excitation and erection. These organs possess an individual life which is very involuntary, which is torpid during a greater part of their existence, which awakes at certain epochs, in the same manner as our active life, which reposes every night and awakes every morning. This vitality of the sexes is less durable than that of individuals, for it does not commence until the age of puberty, and it dies before the body that produces it. Thus the plant does not develope its flowers, for the first time, but at a certain period of its existence ; the animal does not become pubescent until its organs and powers are sufficiently develope^d. In the same manner, the vegetable and animal which are too old, are dead as to reproduction. Their sexual organs are hereafter incapable of performing this function. The duration of living bodies may be divided into three periods, the two extremes of which are the frozen zones of existence, the intermediate is the torrid zone of life.

Love, however, announces the speedy ruin of individuals. We love, because we do not live for ever. Every living being reproduces itself, because all perish. Love is the messenger of death. If nothing perished, there would be no need of new generations, and love would be exiled from the world. Minerals are in this condition, they never die, but they never engender. We pay love at the expense of our life. Who can suppose that this sentiment, so delightful, should nevertheless be a proof of our mortality? We give our life to other beings, as a father who

divides his goods among his children. To engender, is to say, to make his will, and to prepare for death. But nature has surrounded the act of generation with so many attractions, that she has entirely disrobed it of all sadness as regards us ; nevertheless, when propagation is accomplished, an animal falls into depression and sadness, it perceives fatal losses ; the plant is deflowered, its petals are withered, its freshness is destroyed, its beauty has vanished with the morning mist, its bitterness remains, as Lucretius has it :—

“ ————— E fonte lepōrum
Surgit amari aliquid quod in ipsis floribus
angit.”

It is a mixture of grief and pleasure which makes the great charm of love. It is necessary that pain should prevent the satiety of pleasure, and that pleasure should soften the suffering of pain ; without this compensation, love would be very soon exhausted, either by satiety, or by pain, like a fire ; but thus good is counterbalanced by evil ; that love subsists like a fire, which does not exist but by a continual action ; no one loves, unless agitated by hopes and fears ; because we remain indifferent whilst the soul is in repose. Love is in the combat, not in the victory ; it languishes in the bosom of pleasures, and reanimates by obstacles ; contradiction or opposition is its life ; that which torments it, pleases it, whilst that which constitutes its happiness causes its destruction.

VI. *Of copulation, and of the phenomena of impregnation ; of the unions of the different species, of pregnancy, and parturition ; of twins ; and the mode of nutrition of the fetus.*—We shall not enter here into the details, which relate to the preparation of the seminal fluid in the testicles of the male, nor into all the physiological phenomena which accompany copulation. Here we shall treat of the genital function in its generalities in all organised beings, and compare them with what is observed in the mammiferæ, and our species. The copulation of animals is more complicated than the act of generation in vegetables : when an animal enters the season of love, it is agitated and loses repose ; an ardour of inquietude torments it ; a secret fire devours it, it exhales in its whispers, and announces its wants by its cries and accents of tenderness : the bird in its cage chants its pains and its pleasures ; it calls its true love, constructs its nest, and defies its rivals to combat. The time of love is also the period of strife among animals. Jealousy is a passion instituted by nature, and destined (who will believe it) to enable the offspring to reject the feeble and the diseased, and to give preference to young, vigorous, and robust individuals, so that the species may maintain itself in all its vigour or power. Jealousy is a misfortune to an individual, but it is useful to the species, and considers this object only. As I have al-

* The ablest physiologists deny this, and it is well known to every obstetrician, the amorous impulse is extinguished in most women during menstruation.—*Trans.*

ready stated, this is the reason that so many animals combat to enjoy it. Love is the brother of war, and Mars is always loved by Venus. Females of all animals prefer the most courageous males by an amorous instinct, which is very remarkable. The feebleness of the one aspires after the strength of the other; courage is the first title of love; the fervour of age, the vigour of the limbs, the activity of instinct, the impetuosity of the passions, and the vehemence of the appetites, announce that the individual is not incapable of giving life. When we examine the human species, we find how much nature is cherished by social fetters, which become more powerful by religion and laws in the age of love. All the fine sentiments which decorate the title of moral love, all the metaphysics of sentiment and delicacy emanate almost from the physical condition, and belong to it. Graces, charms, and amiability are physical qualities, and it is from these that love emanates. The moral condition has, I know, great influence on love, but these moral qualities, so powerful on sensitive hearts, have a deep root in the body, and are not independent of it.

Love, upon which so many reason, is it not known to all? Nature, much more ingenious than man imagines, directs the moral and intellectual faculties to the good of generation. It is an error to consider love a mere brutal and carnal passion; man seasons it with modesty, attachment, and mutual tenderness; love requires a total abandonment of his object; it inspires a total and reciprocal abnegation, it occupies the whole soul; it gives the gift of life itself. Whoever does not know that he must die, is incapable of true love. The attachment of the world, the laws of society, human conventions, every thing must yield to it; behold love as nature made it—it is master of every thing, or it is nothing. We think we love an individual on her own account, but it is most true that we do not really love her; it is her reproductive faculty, that which emanates from her, it is the posterity of which she is the depository; for when a woman is no longer capable of engendering, love entirely ceases. We also observe that most men have less love for a pregnant woman than for one who is not in this condition, although they entertain great respect for the first, but great tenderness and veneration for the second. Our sentiments are naturally proportioned, and by instinct, with the state of woman. Nothing is blinder or more clear-sighted than love; and it is this that renders it inconceivable. It exhales its emanations of sympathy between the sexes. There is such an accord between certain individuals, such a harmony between certain temperaments, that one loves one person, and hates another without knowing the reason why.

What is this sympathy of hearts, those secret ties which attach the sexes by mutual love? Whence proceeds that concordance more powerful than our life, and by which we become capable of exposing it to a thousand deaths for her whom we love? Why are the most violent loves transformable into the most intense hatred? There is no medium in ardent souls. This impetuosity of sentiments is derived from the physical condition. These relations of sympathy are nevertheless the result of a harmony of age and character, of the sensibility and correspondence between the moral state of the one sex, and the other. Nature is by no means content with the physical condition alone—she wishes the entire individual, to immolate it to posterity. We estimate the mind of a man by the greatness of his moral love. That which we call lukewarmness of love, is a smallness and nullity of mind, such as we see in those who are engaged in ordinary pursuits, and incapable of enthusiasm.

When the whole mind is not absorbed in the act of sexual union, the products are feeble and delicate as we generally observe in the infants of men who make great mental exertions. The sons of celebrated men are almost unworthy of their fathers. We never see a great man engender great men. The sons of Socrates, Hippocrates, Chrysippus, Pericles, Thucydides and Cicero, among the ancients; of Racine, La Fontaine, Henry IV. of France, Napoleon, Crebillon, John Hunter, Cullen, and a thousand others which might be cited, not one of them resembled his father. On the contrary, most of the men who became illustrious by character, genius or valour have been the fruit of ardent love, and had for parents vulgar men, whose merit was entirely physical. A great number of celebrated men were illegitimate, who were truly the sons of love. Nevertheless, many women have pretended to have conceived without having participated in pleasure; others have been impregnated during sleep; but these facts admit of doubt, for it appears to be scarcely probable that conception could be possible without an intimate and tacit consent of organs, much less that the will was really wanting. It must be remembered that amorous ideas exist during sleep, and induce the seminal emission of man; and therefore we may reason from analogy, and conclude that they exist in the human female. Aristotle asked why deformities and monstrosities were more frequent in the human species than in other animals; and he believed the cause to be, that our species sometimes perform the generative act negligently, and are thinking of other matters; while beasts perform love more simply and give themselves entirely to it; and thus it is that rustics living in villages or the country, who are generally robust and vigorous, produce the finest and strongest infants, because they follow nature's

dictates more closely than the great people of the age, who are devoured by passions, burthened with anxieties and troubles, absorbed in difficult affairs and abstract meditations.

The pleasure that nature joins to sexual union is the only attraction of reproduction, an attraction so imperious and tyrannical as to be required as powerfully as any other want; for animals are impelled to it by an instinct stronger than life: *in furias ignesque ruunt amor omnia ibidem*. Even before they have a knowledge of the pleasures of it, they have an involuntary presentiment of it: *mentem Venus ipsa dedet*.

Among apes, parrots, pigeons, ravens and other birds the moment of enjoyment is preceded by kisses and tender caresses, as in the human species. Apes, bats, hedge-hogs, and porcupines, seals, or sea-calves, the cetaceæ, (whales), copulate abdomen to abdomen, whilst the others copulate like quadrupeds; dogs, wolves, and foxes remain in close union in the venereal act, because the gland of the male swells very much, and the vagina closes by contraction, so that the male organ is arrested during the time of the ejaculation of the seed; and this is necessary in these animals, as they are deprived of seminal vesicles, and their seed is not darted into the uterus, but distilled drop by drop. If they are separated at the moment of this slow ejaculation, the female will not be impregnated, and the species will be extinct. Female and male animals are mutually attracted and excited by the odours which they exhale in the time of rest, and which is secreted by the glands. These odours are placed near the sexual organs in beavers, civet cats, &c.

In all the mammiferous animals there is an ingress or intromission of the male organ, and the female have a clitoris or organ of pleasure. The moment of sexual enjoyment is accompanied by a universal trembling of the whole body, and a kind of slight convulsion, which ends in a comatose or extatic state. Coition has been compared to a fit of epilepsy, and many of the characters of both are similar; for the former entirely absorbs the mind and body; we too neither hear nor see anything; all is death, except pleasure; the soul is absorbed in love, and some persons have lost their lives in this crisis. (*Schenk de Coitu; Marcel. Donat. Hist. Mirab. lib. v. cap. 17*). And thus it is, that coition is mortal in certain nervous diseases, or after great wounds or hæmorrhages, &c. or when it is too often repeated, it ruins and destroys the whole of the living economy. It is right to think before we engender, as we are about to deprive ourselves of life, and to shorten our days; and this is the proof that enjoyment of sexual love is mortal, as no one can communicate life but at the expense of his own.

It is remarkable that the sperm has the same odour as the pollen of most plants.

This odour belongs to many plants, the berberis, the fagi, &c. The pollen of vegetables contains very small capsules, which humidity opens; and according to Bernard and Jussieu, a very subtle powder escapes and penetrates into the pistil of the ovary. Microscopic animalcules are observed in this sperm of animals, but these have nothing to do with fecundation, contrary to the opinion of Læwenhoeek, Hartsoecker, and Vallisnieri, since Spallanzani fecundated the eggs of frogs with particles of sperm perfectly exempt from these animalcules.

It has been said that males enjoy more pleasure than females, as the latter are more tranquil and less agitated by enjoyment. It appears that the female has a sweet pleasure, a kind of intimate felicity, while pleasure is stronger and more poignant with the male. It is he in general that seeks and solicits, while the female attends and yields. This combination was necessary, because the male cannot act but at certain moments; but the female is almost always ready. Some animals, as the cat species, go and seek the male. We hear them at midnight express by lamentable mewings, the violence of their desires, their amorous rage. Nothing so readily excites rage as violent love: under this influence life knows nothing else; dangers, combats, wounds, are the ordinary effects of this cruel passion. Love commences in rage and is often concluded by a mortal hatred. The uterine organ sucks or rather aspires the fecundating sperm to the ovaries, while the fallopian tubes seize the ovaries and allow the prolific fluid to pass to those organs.

Love is still more ardent among birds than among quadrupeds, on account of the warmth of their constitution and their extreme vivacity. Their coition is rapid and frequently repeated. A cock copulates with twenty or thirty hens in some hours. These birds have not a perfect penis, but only a kind of tubercle; there is no ingress or intromission, but a simple affrication. Woodcocks fall into an ecstasy during the season of love; and many birds in cages, which cannot enjoy their females, die of desire, and chant it with a sort of rage; for the songs of birds are the expression of their love—they chant no longer than they have amorous desire; and such is the fact as regards the cries of quadrupeds.

Cold-blooded animals are more languid in love than the preceding, such as lizards, serpents, &c. It is clear that the more vivid the pleasure, the more rapid, because if prolonged, it would necessarily destroy the power of life; while on the contrary, the slower it is the more feeble. It is remarkable, that cold-blooded animals, as lizards, serpents, &c. have a slow copulation and remain many days in it. They are then in a state of stupor and immobility; they neither eat nor stir, as if wholly engrossed in their pleasure. The genital organs of both sexes

become congested, hot and vascular, and those of plants have acquired a temperature from 20 to 80 degrees of Reaumer.

The female animals have a kind of modesty, and it is this perhaps that leads the males to search after them. The fervour of love is much greater in males when they have a great number of females; and thus it is that the polygamous are much more ardent in love than the monogamous, which are more generally cold and insensible. The females of cold-blooded animals are not well fitted for procreation, and hence the animals effect this function without the body. It is for this reason too, that nature arms the males with claws, harpoons, &c. to grasp and excite females.

The sexual unions of quadrupeds are, in general, vague and without choice, the male selecting the first of his species, whilst he always prefers the most vigorous females, which seek and prefer the most vigorous males. Thus we observe very small bitches copulate with large dogs, as if instinct had much more regard to the perfection of the species than to the pleasure of the individual. Monkeys are monogamous, but they do not always confine themselves to one female. The ruminating animals are polygamous, and they fight for their females. The sea-calves have their seraglios which they stoutly defend, and are as great tyrants over their females as the despots of Asia in their harems.

—o—

A NEW PRACTICAL FORMULARY

OF HOSPITALS, OR A

Collection of Formulæ of the Civil and Military Hospitals of France, Germany, Italy, Great Britain and Ireland, &c., containing the Indication of the Doses in which simple Substances, magistral and officinal Preparations of the Codex are administered, the use of New Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M. D., and P. VAVASSEUR, M.D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M. D. &c. &c.

(Continued from p. 211.)

Anti-dysmenorrhœal Mixture. (Ryan.)

Rx. Misturæ camphor, ʒ vss;
Tinct. guiaci. am. ʒ vj;
Liq. ammon. acet. ʒ j;
— opii sedat, ʒ j—iss;
Syrupi aurant. ʒ j.

Fiat mistura, de quâ, unum cochleare, amplum, mane, vespereque exhibeatur.

[This mixture is often beneficial in painful menstruation caused by irritable uterus in hysterical women. A tea-spoonful of laudanum is an old remedy in this country. Guaiacum is strongly recommended by Pro-

fessor Dewees, of Philadelphia, and acetate of ammonia by Professor Masyer, of Strasburg, and M. Cloquet, of Paris. (See *Ryan's Manual of Obstetrics, &c.*, 3rd Ed.) I have therefore combined them. It is to be recollected that dysmenorrhœa may depend on many disorganizations, which no medicine can relieve. T.]

Anti-arthritic Mixture. (Ryan.)

Rx. Misturæ camphoræ, ʒ v;
Tinct. guiaci, am. ʒ v;
Liquoris colchici, m xx;
Syrupi simplicis, ʒ iij.

Sit mistura, cujus capiat, cochl. ampl. tertiâ vel quartâ quâque horâ.

[This mixture is extremely beneficial in chronic rheumatism and gout, in the daily practice of the Western Dispensary, Westminster. I believe the liquor colchici is an aqueous solution. It has also been used with remarkable success at St. Bartholomew's Hospital. It has repeatedly succeeded in my practice, when the other preparations of colchicum had failed. It is also strongly recommended by Dr. Hue and Dr. Latham, of St. Bartholomew's Hospital, and also by Sir Charles Scudamore. T.]

SARSAPARILLA.

A stimulant, which appears to have a particular action on the skin, although it does not often promote perspiration. Very frequently employed, either alone or united with other vegetable sudorifics, in the treatment of constitutional venereal affections, chronic rheumatism, diseases of the skin, ulcerations of the larynx and pharynx, dependant on syphilis, or on the abuse of mercurials, &c.

Subst. incomp.—The infusion of galls, lime water, the acetate of lead, &c.

INTERNALLY.—*Powder.* ʒ ss—3 i. Seldom used.

Decoction. ʒ ij—iv, in ʒij of water reduced to i.

Sirop. ʒ i—ij.

Sirop. de Cuisinier. P. ʒ ss—i, in a sudorific ptisan, or as a vehicle for the corrosive sublimate, in the treatment of syphilitic affections.

[A vast deal of discrepancy of opinion prevails as to the best mode of preparing sarsaparilla for use. Dr. Hancock instituted, as incidentally alluded to in a former page, a great number of experiments on patients, by exhibiting the infusion, decoction, and extract, as prepared according to the British Pharmacopœias. He is convinced that long boiling destroys the medicinal property of this powerful remedy, and that the extract is totally inert. Repeated and multiplied experience has led him to the conclusion that infusing sarsa in hot water kept near the boiling point, is the best mode of preparation.—*Trans. of the Medico-Botanical Society of London, 1829. Part I.—Reviewed in the Lond. Med. and Surg. Journ. 1829, v. 3.*

Dr. O'Beirne, of Dublin, has found most benefit from an infusion of sarsaparilla in lime-water. He relates several cases of secondary syphilis cured by this combination, after the patients had taken large quantities of all the other preparations without effect. He has also employed it during the last 15 years (since 1820) in mercurial affections which had resisted all other preparations of this remedy. He has likewise found it a powerful auxiliary in nervous complaints, in cases of debility and loss of health from various causes, in scrophulous enlargements of the lymphatic glands, and in irritability and chronic catarrh of the urinary bladder. He states that beneficial effects are seldom observed sooner than the third week of its use, and the kidneys are the only organs on which it appears to exert any sensible action. Mr. Carmichael, the eminent colleague of Dr. O'Beirne, recommends the preparation about to be inserted in very strong terms. After many experiments on infusions of different strengths, the following is that preferred, and I beg to add the expression of my fullest confidence in the efficacy of this formula.

Compound Infusion of Sarsaparilla.
(O'Bierne.)

R_x. Rad. sarsaparillæ Jamacens, concisæ, ℥ iv;
Rad. glycyrrhizæ, ℥ ss;
Liquoris calcis, Oij.

Macera per horas viginti quatuor in vase vitreo optimè operculato, et in loco frigido et obscuro; dein cola in usum.

Sumat hujusce infusi dimidium, partitis vicibus, quotidie.

"This formula," says Dr. O'Beirne, "differs from that of the Dublin Pharmacopœia, first, in containing double the quantity of sarsaparilla; secondly, in containing liquorice root; thirdly, in requiring the infusion to proceed for twenty-four instead of twelve hours; fourthly, in not requiring agitation of the vessel. This formula also differs from that given by Dr. Copeland, first, in containing double the quantity of sarsaparilla; secondly, in not requiring the sarsaparilla to be bruised; thirdly, in not requiring agitation of the contents of the vessel; fourthly, in requiring the glassful to be very well, instead of slightly stopped." Dr. O'Beirne further states, that the reason he prescribes the lengthened period for the infusion was founded on an experiment. On passing a stream of carbonic acid into a quantity of infusion, which had been prepared in twelve hours, the fluid, which was previously clear, became quite turbid, and there was a white precipitate. On passing the gas into an infusion prepared in twenty-four hours, the fluid remained clear, and there was no precipitate.—(*Dublin Med. Journ.* 1834-5). *Op. Cit.*

It is of the utmost importance to the practitioner to be made acquainted with the proper formula for preparing a remedy which has long maintained a high place in the materia medica, but which has been unjustly deprecated of late years. The recommendation of one of our ablest physicians, who has enjoyed the most extensive experience during a long military service of the late war, and since the peace, in the largest hospitals in Dublin, as well as in a first-rate private practice, will be generally, if not universally adopted by the profession in all countries. T.]

Ptisan of Sarsaparilla. H. des Ven.

R_x. Sarsaparillæ, ℥ i—ij;
Aquæ, Oiv;

Decoque ad dimidiam, et cola. Cyathus sumendus pro dosi.

The Decoction de Sarseparielle of the Hot. D. contains ℥ i of the resin to Oiv of water.

Compound Decoction of Sarsaparilla. H. of London.

R_x. Decocti sarsæ. fervent. Oiv;
Radicis sarsæf. concisæ,
Guaiaci ligni rasi,
Glycyrrhizæ rad. contusæ, āā ℥ i;
Mezerei rad. cortisis, ℥ iij.

Decoque per quartam horæ et cola. ℥ iv—vj sumendæ ter in die.

Sudorific Ptisan. Hot. D.

R_x. Sarsaparillæ,
Guaiaci ligni, āā ℥ ss;
Sassafras, ℥ ij;
Aquæ, Oiv.

Coque et cola. Sumatur cyathus pro dosi in die.

Ptisan de Felts. (Lagneau.).

R_x. Sarsaparillæ, ℥ ij;
Smylacis, ℥ i;
Cort. buxi, āā ℥ iss;
Antim. sulph., ℥ iv;
Bichloratis. hydrarg. gr. iij;
Aquæ puræ, Oij.

Decoque ad dimidiam partem.

The antimony should be enveloped in a piece of linen, and suspended in the fluid during ebullition.

Employed in the treatment of chronic venereal affections. The dose is Oij. daily, taken at several times.

The *Ptisane de Felts* of the H. des Ven. does not contain either the sublimate or the smylax; but the quantity of the antimony is half as much as in the former ptisan. It is used in the same cases.

The *Decoction de Sarsepareille Comp.* of the H. de la Ch. very much resembles the preceding; the quantity of sarsaparilla is ℥ iv to Oiss of water, and that of the antimony ℥ i. It is used in the same manner and in the same cases.

Ptisan, called *Liqueur de Pollini*. H. de Ven.

Rx. Sarsaparillæ,
Cinchonæ, āā ʒ iij;
Pumicis,
Antim. sulphur, āā ʒ ss;
Aquæ puræ, Oviij;
Coque ad dimidiam, et adjice,
Potassæ subcarb., ʒ ij.

Misce.

Dose as in the preceding cases.

Anti-venereal Decoction. H: of Italy.

Rx. Sarsaparillæ, ʒ i;
Lichinis island, ʒ iiss;
Aquæ, q. s.
to obtain ʒ xiv of fluid, to which should be added,

Syrupi simplicis, ʒ i.

Fiat decoctum et divide in partes duas
sumat unam mane et nocteque.

Sirap de Chissinier Réformé. H. des Ven.

Rx. Sarsaparillæ,
Guaic. lig. ras. ā ā lbi;
Aquæ puræ, Oxij;
Sacchari,
Mellis, ā ā lbiiss.

Fiat syrupus.

It is principally used as a vehicle for the
Liqueur de Van Swieten.

[There are numerous drugs sold in London for sarsaparilla which are spurious articles. I have lately had a gentleman under my care, who purchased fourteen pounds avoirdupois of what was sold to him as the best sarsaparilla, and who made this quantity into decoction, and took it for secondary syphilis, without the slightest benefit. One pound of the genuine article restored him to health. T.]

SMILAX.

Used in the same cases as sarsaparilla, to which it is generally united. It cannot be depended on when used alone.

INTERNALLY.—*Decoction*. ʒ ij—iij in Oij of water.

[It is seldom used in this country. T.]

The *Decoction de Squine* of the Hot. D. contains only ʒ i of smilax to Oij of water.

Compound Decoction of Smilax. (Swediaur.)

Rx. Smilacis,
Uvæ passæ, ā ā ʒ i;
Aquæ puræ, Ovij;
Coque ad Oij, et cola. Cyathus sumendus pro dosi.

SASSAFRAS.

A stimulant, generally employed as a sudorific in the same cases as guaiacum, with which it is frequently combined.

INTERNALLY. *Powder*. ʒ ss—i. Not much employed.

Eau distillée. P. ʒ i—ij.

Huile essentielle. P. Gutt. ij—x.

VOL. VII.

Compound Lime Water. H. of Italy.

Rx. Sassafras, ʒ ij;
Myristicæ, ʒ iij;
Glycyrrhizæ, ʒ i;
Aquæ calcis, Oiv.

Macera per horas quatuor et viginti, et cola. ʒ ij—iv sumantur sæpe in die.

In scrophulous diseases.

MEZEREON.

A stimulant and diaphoretic. Recommended in cases of constitutional herpes, scrophula and syphilis, &c. Not much used.

EXTERNALLY. It is employed as a rubefacient, and even a caustic. It is also used to establish exutoria, and to prolong the suppuration of those already existing.

INTERNALLY. *Powder*. Gr. i—x. Not much used.

Decoction. ʒ i—ij in Oij of water.

Decoction of Mezereon.

Rx. Rad. mezerei, ʒ ij;
Aquæ fontanæ, Oijj.
Coque ad tertiam partem et adde,
Glycyrrhizæ contusæ, ʒ ss.
ʒ iv—vi. sumantur ter in die.

In chronic syphilitic diseases.

EXTERNALLY. As a vesicant. A small quantity macerated in vinegar applied to the skin.

Pommade de Garou. P. Any quantity.

SUMACH.

In large doses a narcotic, acrid poison; in smaller ones an excitant, which appears to exert a particular action on the skin. It is employed in certain cases of herpes, chronic rheumatism, paralysis, &c. Not much used in France nor England.

INTERNALLY. *Powder*. Gr. i—iv, in pills.

Decoction. ʒ i—ij in Oij of water.

Extract. P. Gr. x—ʒi daily, and more progressively.

Pills of Sumach. H. of Italy.

Rx. Pulv. toxicodendri, gr. i;
——glycyrrhizæ, ʒi;
Succi sambuci, q. s.

Divide in pilulas iv sumendæ in die.

Excitant Potion. H. of Italy.

Rx. Extract toxicodendri, ʒ i;
Aquæ fontanæ, ʒ i.

Misce.

In dosibus, gutt. x, quotidie.

BITTER-SWEET.

A stimulant of the cutaneous system. Much used as a sudorific, in rheumatic and venereal affections, scabies, and many other diseases of the skin. Not so much used as formerly.

INTERNALLY. *Powder*. ʒ ss—j.

Decoction and Infusion. ʒ ss—i to Oij of water.

Compound Decoction of Bitter-sweet. H. of Italy.

Rx. Dulcamaræ, \mathfrak{z} ii;
Glycyrrhizæ,
Arctii lappæ,
Sassafras,
Guaiaci, $\mathfrak{a} \mathfrak{a}$ \mathfrak{z} ij;
Aquæ, Oij.

Decoque ad Oj, et cola. Capiat cyathum pro dosi.

In rheumatism, venereal diseases, &c.

ELDER (FRUITS AND FLOWERS).

A slight excitent and diaphoretic. Employed in rheumatism, gout, and all affections in which it is necessary to excite abundant perspirations.

EXTERNALLY, it is used in lotions, fomentations, ointments, &c. as a resolvent.—[But rarely employed in this kingdom. T.]

INTERNALLY. *Flowers. Infusion.* \mathfrak{z} j—ij in Oij of boiling water. The dose is a small cupful, hot, often repeated.

The Infusion de fleurs de sureau, of the Hot. D. and De la. Ch. contain \mathfrak{z} ij of the flowers.

Ptisane de fleurs de sureau. P. Taken in the same manner.

Eau distillæ. P. \mathfrak{z} ij—iv, as a vehicle,

Fruits. Rob de sureau. P. \mathfrak{z} iss—ij as an excipient.

[Some empirics in Ireland place great confidence in elder ointment in scrofula, using at the same time the "sweetening woods" already noticed. One of these persons proposed to cure a nobleman, who died of scrofula, with this nostrum. A relative of his was relieved by me of dysentery, and his friend, the empiric, offered to inform me of his ointment for fifty pounds sterling; but at length described it. I told him, it was a most inefficient remedy, and that it had fallen into disuse.

Oxymel of Elder. H. of Germ.

Rx. Aceti sambuci, unam partem.
Mellis, duas partes.

Decoque, linto igne.

It is used to sweeten diaphoretic drinks.

EXTERNALLY.

Resolvent Fomentation.

Rx. Infusi sambuci, Oj.
Spirit. camphoræ, \mathfrak{z} iv.

Fiat fofus.

TEA.

When taken hot, tea acts as a diuretic and diaphoretic; it is a powerful assistant of digestion.

[Black tea is a wholesome stimulant, but is injurious when the infusion is taken too strong. Green tea is excessively injurious. (See Translator's Lecture on Tea, delivered before the Medico-Botanical Society, Lond. Med. and Surgical Journ.)

Substances incompat. The salts of iron, gelatine, and lime water.

INTERNALLY. *Infusion.* \mathfrak{z} i—ij in Oij of boiling water.

SWALLOW ROOT. (Dompte-Venin.)

Taken in large doses, an emetic and purgative; in smaller ones, a diaphoretic. Not much used at the present day.

INTERNALLY. *Powder.* Grs. xvij— \mathfrak{z} ss in boluses.

Decoction. \mathfrak{z} ss—i to Oij of water. The roots of LOBELIA SYPHLITICA, of ASTRAGALUS, &c.; the woods of SANTALUM, RHODIUM, &c. possess diaphoretic properties, and may be employed in the same cases as the preceding substances; they are not, however, much used at the present day.

There is a syrup made from the petals of the red carnation, which is said to sweeten ptisans and diaphoretic potions, in doses of \mathfrak{z} i—ij.

The Espèces Sudorifiques pour Infusion. P. are composed of the following ingredients.

Rx. Sassafras,
Florum sambuci,
Folior. buglossi,
Petalæ rhæodon, $\mathfrak{a} \mathfrak{a}$ p. e.

The dose is \mathfrak{z} i to Oij of water.

The Espèces Sudorifiques pour Decoction. P. are composed of the following ingredients.

Rx. Guaiaci rasidi,
Sarsaparillæ,
Sonilacis, $\mathfrak{a} \mathfrak{a}$, p. e.

\mathfrak{z} i—ij in Oij of water reduced to a third.

VAPOUR BATHS.

In the hospitals these baths are prepared by putting hot water into a particular apparatus; but in private practice the use of the apparatus may be substituted by placing the patient in bed, and conveying to him a curved glass tube, whose opposite extremity is adapted, by means of a hole in the cork, to a bottle three parts filled with water, and placed on a chafing-dish.

These baths stimulate the skin in a high degree, and determine a copious perspiration. They are employed with advantage in rheumatic and cutaneous affections, &c.

Aromatic Vapour Baths. H. de Paris.

These baths are prepared by causing the vapour of water to pass through some aromatic plants placed in the apparatus of simple vapour baths.

CHAPTER VII.

MEDICINES WHICH ARE EMPLOYED TO ACT ON THE ORGANS OF GENERATION—EMMENAGOGUES, &c.

[THE secale cornutum and iodine, are, perhaps, the only medicines now in use, which have a direct influence on the uterus, when administered internally, T].

CANTHARIDES.

In large doses, cantharides is one of the most energetic acrid poisons, acting violently on the urinary organs, and often producing stranguary, hæmaturia, priapisms, &c.

In smaller doses it is administered in certain cases of paralysis of the bladder, impotence, chronic gonorrhœa, &c. English practitioners affirm that it is serviceable in epilepsy, certain diseases of the skin, &c.; but it is a dangerous medicine and not much used, except externally as an epispastre.

INTERNALLY. *Powder.* Gr. i—iv in pills.

Tincture. P. gutt. iv—x in an emulsion. This tincture contains 1-55th of the soluble principle of cantharides.

Diuretic Powder. H. of Germ.

Rx. Pulv. cantharid. gr., iv;
Camphoræ, gr. viij;
Sacchar. lactis, ʒ iij.

Divide in chartulas sex, sumendæ in die.

Pills of Cantharides. H. of Germ.

Rx. Pulv. cantharid. gr. vi;
Sacchari. ʒ ij;
Pulv. cinchonæ, gr. ij;
Syrupi rosæ, q. s.

Divide in pilulas xxx, quarum sumat, ij—vj. secundâ quâque horâ.

Each pill contains 1-5th of a grain of cantharides.

Pills of Cantharides with Opium. H. of America.

Rx. Pulv. cantharides, gr. xvij;
Opii pulveris,
Camphoræ, ʒ ʒ gr., xxx;
Conservæ. rosæ, q. s.

Fiant pilulæ, xxxvi, quibus capiat unam vel duas omni mane.

Each pill contains grs. 1½ of cantharides, & gr. i. of opium.

[These pills have been long since recommended in the pharmacopœia chirurgica by Wilson, in certain cases of impotence. Sir Astley Cooper has combined cantharides and chio turpentine in paralysis of the bladder. The tincture of lytta is strongly recommended by Dewees, Mackintosh, and others in amenorrhœa, and leucorrhœa, the dose being increased to a drachm and a half, twice or thrice a day; but I have never known a patient bear more than one sixth of the quantity. T.]

Infusion of Cantharides. H. de la Ch.

Rx. Lini semin. ʒ ij;
Glycyrrhizæ, ʒ i.

Macera per quartem horæ, cola, et adde,
Tinct. cantharides, gutt. v.

Sumatur mistura in die.

In Cases of Paralysis of the Bladder.

The quantity of the tincture should be gradually increased, and may be carried to 60, or even 80 drops daily.

Mucilage of Cantharides. H. of Germany.

Rx. Tincturæ cantharidis, gutt. iv;
Mucil. acaciæ, ʒ iv;

Misce.

Cochleare magnum adhibeatur tertiâ quâque horâ.

In chronic Gonorrhœa, and Leucorrhœa.

A spoonful weighing 5 drachms contains 5-8ths of a grain of cantharides.

Emulsion of Cantharides. H. of Germ.

Rx. Pulv. cantharidis, gr. xx;
Amygdalæ dulcis, ʒ i;
Sacchari, ʒ p.

Tere in mortario et adjice,

Aquæ fervent, ʒ x.

Cola sumat æger cochleare magnum secundâ quâque horâ.

In the same cases as the preceding preparation.

Diuretic Potion. H. of America.

Rx. Tinct. cantharidis, ii.
Ætheris nitrosi, ʒ ʒ gutt. x;
Sacchari, ʒ i;
Aquæ menthæ, ʒ iij.

Fiat haustus, cujus capiat cochleare minimum tertia vel quarta hora.

Each spoonful contains about 3½ gutt. of the tincture, and the same quantity of nitrous æther.

EXTERNALLY. *As an epispastic.*

Emplâtre de Cantharides. P. the powder of cantharides. q. s.

[*Aphrodisiac Lozenges.*

Rx. Panacis. v. fol. pulv. ʒ v;
Vanillæ aromat. ʒ x;
Succini essentizæ, ʒ ss;
Tincturæ by litta, ʒ v;
Olei cannellæ, m l;
Sacchari purif. lbxij;
Mucilag. acaciæ, q. s.

Tere intime et divide in pastillos, gr. xxiv, ex quibus sumantur tres vel quatuor ter quaterve de die.

It is doubtful whether there are any aphrodisiac remedies; though the following have been lauded by different writers.]

We find many vegetable substances produce effects on the reproductive system of different individuals. Thus the genus of plants called *umbelliferae*, as the artichoke, celery, seeds and root of parsnip, carrot, and fennel. The *cruciferae*, as radish, turnip, water-cresses, and rockets, which were strewed at the temple of Priapus;

"Et quæ frugifero seritur vicina Priapo
Excitet ut Veneri tardos eruca maritos."

In the class *acotyledones*, the orange, mushrooms, especially the former kind, which with sweetbread were so lauded by Ovid. The French also include the *leguminous* plants—beans, especially those called French beans, which from their flatulent properties in distending the intestinal canal in the vicinity of the spermatic cords, excite the circulation in them, and thus ultimately excite the testes, inducing artificial plethora, or increased circulation of blood in these organs. We must not forget the class *gy-*

nandria-diagynia of Linnæus, the *orchis*, *ophiris*, and *satyrion*. The bulbous roots of these plants resemble the testicles, exhale a spermatic odour, which has long fixed the attention of men, and induced them to think these excited love. Linnæus states that the leaves of *orchis bifolia* render bulls more ardent and vigorous for copulation. This class is highly nutritive; and hence the bulbs may be given with sugar, or in any other convenient manner. We find, in Genesis, that Rachel married Jacob: but had no family until she ate a certain plant, when she conceived of Joseph. This plant is called *dudaim* in the Hebrew text, and is called *cucumis dudaim* by Linnæus, a species of *orchides*: of this family is also the salad, which is prepared as an article of diet, in the proportion of 3 ss to Oij of water.

The sweet fruits, as peaches, pine-apples, raspberries, &c., are styled *spermatopia*. Of all the foods, fresh eggs are the most powerful aphrodisiacs. Chaumonton praises a fresh egg and chocolate, the yolk especially, as highly nutritious and aphrodisiac; and even we have a proof afforded by analogy from the stallion, whose generative functions are wonderfully increased by the use of eggs and sweet milk. We find it recorded, that Alcimenes, an Athenian, had triumphantly made fifty women mothers in one night!!! But perhaps this demigod had taken a few poached eggs to supper. It is also stated, that crabs, lobsters, pigeons, almonds, and hazel-nuts, have wonderful influence on the genital functions, as also oysters, crayfish, and all cartilaginous fish. It has been long observed, that the Japanese, and other ichthyophagous nations, are highly prolific. There is no more prolific people than the Irish, the lower orders of whom almost wholly subsist on potatoes and fresh eggs; but we should recollect, that the greater part of our arrow-root now in use is made from the potatoe, according to Dr. Paris. (*Pharmacologia*). Phosphorus is a most powerful aphrodisiac; but cannot be exhibited, being a violent poison. Animals, to which it has been exhibited, died of the most violent and amorous convulsions. Borax has been exhibited to horses, and renders them most ardent; and that produced from sea-salt is best, which perhaps accounts for the salacity of the residents on the coasts.

In the class *aroides*, we have the *arum colocasia* of Linnæus, which is much lauded by the Egyptians; the flowers of *pathos*, or *calamus aromaticus*, by the Malays. The saffron of the Juddæ is highly praised in the *Ency. Méthodique*. The seeds and leaves of the hemp are in great reputation with the Turks and Indians, combined with musk, ambergris, and sugar. The species *amomum* are remarkably aphrodisiac; galenga, ginger, cardamom, zedoary, curcuma, and the *maranta galanga* of Linnæus, which is extolled by the Egyptians. The *miris-*

tice are also included, as pimenta, mace, canella, myrtle. The Jews caused newly-married persons to repose on the flowers of sage and marjoram; and also used embrocations of oil of *spike* (turpentine). We should not forget the ginseng, celebrated by the Chinese, the betel of the Indian, and the pepper, lauded by Tourtelle and Peyrilhe, or the opium and aromatics used by the Turks. The juniper-berries, savine, and turpentine, have been long considered aphrodisiac, all of which irritate the urethra and vaginal canal, as in leucorrhœa and gonorrhœa. Many animal substances have been praised by the ancients, as the celebrated hypomane, which was nothing but the mucus of the vagina of the mare, which excited the stallion. (*Olivier de Serres, Théâtre d'Agriculture*.) Castor, ambergris, musk, and civet, are also said to be of undoubted efficacy. Prosper Alpinus informs us, that the women in his time rubbed the genital fissure with ambergris and musk, to reconcile the good graces of their husbands, (*Med. Egypt. lib. iii. c. 15*).

There is also a species of lizard, used by the Egyptians, called by the French *scinque marin*, the yellow amber, the cricket, the ant, the spider, and lytta, which the women of Kamtschatka devour to promote fecundation. The use of cantharides ought to be banished from medicine, as it is a most violent poison, and it only causes priapism without desire, or violent strangury and inflammation of the bladder. Paré relates the case of an Abbé, who intended to be chevalier of Venus, and who had taken a dose of this drug, which produced a mortal hæmaturia. A cautious use of this medicine may, however, produce aphrodisiac effects.

The following formula is lauded by the French writers.

Essentia Regalis.

Rx. Ambre grisæ, Oij;
Moschi gran. ʒj;
Zibethi, ʒss;
Olei cannellæ,
—— lig. rhodii ā ā ʒiv;
Potassæ carbonatis, ʒiv;
Tincturæ rosarum,
—— aurant. ā ā ʒiss.

Solidis prius commixtis, dein immitantur olea, et denique tincturæ, stent in lagena bene obturata per triduum, illico coletur liquor.

Dosis mxx—xxx in syrupo ad effectum ciendum.

Certain aliments, as those already mentioned with others, and drinks, as wines, &c. and even milk, excite aphrodisiac effects. T.]

Taffetas Epispastique. P.

Pommade Epispastique Verte. P. Employed to dress blisters that are intended to keep up an active suppuration.

Pommade Epispastique Jaune. P. Em

ployed in the same cases as the preceding, but it does not contain opium.

Oil of Cantharides. P. In frictions.

Tincture. 3 i—ij in frictions.

Liniment de Cantharides Camphré. P. In frictions.

The Liniment Stimulant of the Hot. D. does not differ from this preparation.

The Pommades Epispastiques of the hospitals of Paris differ but little from those of the Codex. At the Hot. D. there is one composed of 3 i of the powder of cantharides; ʒi of lard, and 3 iss of yellow wax. That of the H. de la Ch. contains gr. xii of cantharides and of mezerion, and 3 i of lard and wax.

Epispastic Pomade with Camphor. Hot. D.

Rx. Pulv. cantharides, 3 i;

Aquæ puræ, 3 xij;

Adipis, 3 vi;

Olei olivæ,

Ceræ albæ, ā ā 3 iv;

Camphoræ, 3 ij.

Boil the cantharides with the water for half an hour, then filter and evaporate till reduced to five ounces: add the fat substances: evaporate the whole of the water: let the medicine cool, and add the camphor.

Employed to continue the suppuration of blisters, without causing too great irritation or action on the urinary organs.

Liniment of Cantharides.

Rx. Tincturæ cantharidis, 3 i;

Spiritus camphoræ, 3 ij.

Fiat linimentum.

Used in frictions on parts diseased with paralysis, and where it is necessary to cause a lively stimulation.

Ammoniacal Liniment with Cantharides. H. of Italy.

Rx. Tinct. cantharidis, gutt. xis;

Camphoræ, 3 iss;

Olei ammoniati, 3 iss.

Fiat linimentum.

Excitant Liniment of Turpentine. H. of Germany.

Rx. Tincturæ cantharidis, 3 iij;

Olei terebinthinæ, 3 i;

Liquoris ammoniæ, 3 iss.

Misce.

Cerat of Cantharides.

Rx. Pulveris cantharidis, 3 i;

Cerati cetacei, 3 j.

Misce.

Used for promoting a purulent discharge on a blistered surface.

Cataplasm of Cantharides. H. of Italy.

Rx. Pulv. cantharidis, 3 i;

Micæ panis, 3 iss;

Aceti scillæ, q. s.

Fiat linimentum.

Employed as a rubefacient.

Excitant Injection. (Swediaur).

Rx. Tinct. cantharid. 3 iij;

Aquæ puræ, Oj.

Fiat injectio.

Used for Injections into fistulæ, the cavities of abscesses, &c.

SAFFRON.

In small doses saffron excites the digestive organs: in larger ones it is a general stimulant, which appears to have a particular action on the uterus; the emanations it exhales act strongly on the nervous system. It is used with success in combating lumbar pains, which precede or accompany menstruation in certain females; frequently useful in chlorosis, hysteria, &c. Equally used as a stomachic and antispasmodic. It enters into the composition of many official preparations. [It is a popular, but useless remedy to induce the appearance of eruptions in small-pox, measles, and scarlatina, on the skin. It is rarely employed at present by medical practitioners.—T.]

INTERNALLY. Powder. Gr. xij—Ḑ i.

Infusion. 3 ss to Oij of boiling water.

Electuaire de Safran, or Confection d'Hya-
cynthe. 3 ss—i, and even more.

Tincture. P. Ḑ i—3 i.

Looch de Safran, or Looch Vert. P. A spoonful at a dose.

Sirup. P. 3 ii—3 ss.

Emmenagogue Pills. H. de la Ch.

Rx. Pulveris croci,

—— valerianæ, ā ā Ḑ i;

Oxidi ferri nigri, Ḑ ss;

Syrupi simplicis, q. s.

Fiant pilulæ xii, quarum sumat iv—vj quotidie.

Stomachic Bolus. H. de la Pit.

Tincturæ cinchonæ, 3 iv;

Syrupi tunicæ, 3 i.

Tere in mortario et adde,

Aquæ menthæ,

—— flor. aurantii, ā ā 3 iij.

Misce.

Cochleare magnum omni semi-hora capiendum.

Infusion of Saffron. Hot. D. et H. de la Ch.

Rx. Croci, 3 ij;

Aquæ fervent. Oij.

Macera, et cola. Hujus infusi ferventis cyathus pro dosi sumendus.

As a stomachic and emmenagogue.

It may be sweetened with syrup.

EXTERNALLY. *Infusion.* In lotions and fomentations.

Anodyne Collyrium. H. des Enf.

Rx. Croci, 3 i;
Decoct. lini fervent. 3 iv;
Liquor. opii, 3 i.

Fiat collyrium.

Employed in ophthalmia, accompanied with augmentation of the sensibility of the retina.

Anodyne Cataplasm. H. of Germ.

Rx. Pulv. croci,
Camphoræ, ā ā 3 i;
Olei hyoscyami, 3 ij.

Fiat cataplasma.

Employed to allay the pain in phlegmon.

Hæmorrhoidal Ointment. H. of Germ.

Rx. Pulv. croci, 3 i;
Camphoræ, 3 ij;
Olei hyoscyami, 3 ij;
Ung. plumb. acet. 3 vj.

Fiat unguentum.

Employed in hæmorrhoidal tumours.

SAVINE.

An energetic stimulant, which has a particular influence on the uterus, which it irritates. It is employed in cases of amenorrhœa caused by atony of the uterus, in chlorosis, hysteria, &c. As an external application, it is used as an irritant to fungous ulcers. It is rather a dangerous medicine, and not much used at the present day.

INTERNALLY. *Powder.* Gr. v—3 i twice or thrice a day in pills.

Infusion. 3 i—3 ss in Oij of boiling water.

Oil. P. Gutt. ij—x in a potion.

Emmenagogue Powder. H. of America.

Rx. Pulv. sabinæ,
—— zingiberis, ā ā 3 i;
Potassæ sulphatis, 3 ij.

Divide in chartulas vj, quarum una capiendâ bis in die.

Each packet contains gr. vj of savine.

Emmenagogue Pills.

Rx. Pulv. sabinæ,
Extract. anthemidis, ā ā 3 iss;
Oxyd. ferri nigri,
Extracti aloes, ā ā gr. xv.

Fiat massa, in pilulas gr. ii distribuenda, quarum vj capiendæ pro dosi.

In chlorosis.

Each pill contains little less than a grain of savine.

An Emmenagogue Potion. H. St. Ant.

Rx. Aquæ artemesiæ vulgaris, 3 iv;
—— florum aurantii, 3 ss;
Syrupi simplicis, 3 i;
Olei rutæ,
—— sabinæ, ā ā gutt. vj.

Fiat potio cujus sumat cochl. mag. secunda quaque horâ.

EXTERNALLY. *Powder.* Any quantity on atonic fungous ulcers.

Infusion. As lotions, fomentations, local baths, fumigations, &c.

Cerate of Savine. London.

Rx. Sabinæ foliorum recent, lb i;
Cere flavæ, lb ss;
Adipis præparatæ, lb ij.

Adipi et cere, simul liquefactis. Sabinæ folia incoque; tum per linteum exprime.

Employed as a rubefacient, and even as epispastic.

RUE.

Rue possesses the same properties as savine, only they are not so energetic. It may be used in the same cases. Some practitioners employ it as a vermifuge.

INTERNALLY. *Powder.* gr. xij—3 i in pills.

Infusion. Pinc. i—ij in Oij of boiling water.

Oil. P. Gutt. ij—x.

Emmenagogue Potion. H. de Montp.

Rx. Succu rutæ, 3 i;
Oxymelo scillæ, 3 ss.

Fiat potio cujus sumat cochl. mag. secundâ quaque horâ.

In hysterical affections.

EXTERNALLY. *Infusion.* In lotions, fomentations, &c.

Ointment of Rue.

Rx. Foliorum rutæ,
—— absinthii,
—— menthæ, ā ā 3 iij.
Adipis.

Fiat unguentum preparato, lb j.

Used as a rubefacient and an excitant.

ERGOT OF RYE.

In large doses, this substance is a very active irritant, causing serious accidents, gangrene, convulsions, &c.; in small doses it stimulates the uterus and causes contractions of that organ. It is used in tedious parturition caused by inaction of the uterus, and in hæmorrhages from atony of that organ. When it is administered to hasten labour, its use ought never to be commenced till the natural pains of parturition have ceased or are very feeble, and the os uterus is somewhat dilated.

[The ergot of rye should never be administered during labour, unless the case be natural, the pelvis capacious, and the infant's head presenting by the vertex, or the foot or feet coming down. The maximum dose is 3 iss. Spiraini, Brera, and other Italian physicians have employed this remedy as an astringent, in epistaxis, hæmoptysis, hæmatemesis, hæmaturia, &c., in doses of three grains every three hours, with success. Dr. Negri and I have not only used it in these cases, but also in leucorrhœa with the most decided effects at St. John's Hospital. We also employed it in some cases

of gonorrhœa with advantage. I am in the habit of ordering it daily at the Western Dispensary, and a numerous class of students can attest its efficacy. It is not to be procured genuine from one druggist or chemist in a hundred; and hence its apparent inefficacy. It should be preserved in closely-stopped bottles, and not exposed to air or moisture, or it speedily becomes effete. I have used it to promote uterine action in tincture, ℥ij to Oj of proof spirit in decoction 3iss in ℥vj of water, boiled down to ℥iij, in a close vessel, and seldom exceeded this quantity, given in three doses mixed with milk and sweetened, a quarter of an hour elapsing between each dose, and a longer interval if the uterine action increase. The essence of this remedy and the liquor may also be used with effect. These are, I believe, watery decoctions, and vary in strength according as they are procured from different shops, so that I am unable to state a positive dose. In my opinion, the ergot of rye is an efficient ocytotic remedy, or possesses the power of exciting parturient action at any period of utero-gestation. I feel convinced that it only fails when effete; and I could mention several instances in proof of this statement. A single dose of the decoction has roused uterine action; and then the rest should be left to nature. The practical obstetrician is well aware of the fact, that the parturient action may suddenly increase, without any remedy, after an absence of hours, and terminate the function of parturition very rapidly. He will therefore be content with one or two doses of this remedy when labour pains increase, and leave the rest to nature. He also knows that there is a great danger of hæmorrhage in slow and lingering labour, on account of the want of uterine contraction after the birth of the infant; but a judicious use of the ergot will prevent this dangerous and often fatal occurrence. It will effect this by a contraction of the uterus and the expulsion of the placenta. If given prematurely, or in full doses, it will excite a powerful uterine contraction, impel the head of the fœtus against the undilated or rigid parts of the genital aperture, and destroy the infant. The scientific obstetrician who has watched Nature, knows that the genital aperture is slowly and gradually dilated by the pressure of the infant's head during each labour pain, and, consequently, that it would be wrong to anticipate or force the process of nature by an injudicious exhibition of any remedy, or under any circumstances. It is scarcely necessary to observe, that the premature administration of the ergot, before the infant's head has descended into the cavity of the pelvis, or before the presenting part of the infant can be ascertained, would be rash and dangerous practice. The presentation, to use the obstetric term, might be transverse, the infant might be across, and exciting powerful parturient ac-

tion in such cases, would be followed by the destruction of the life of the infant, or rupture of the uterus, which is a most dangerous disease at all times, and most commonly destructive to the woman. The medicine should never be given before the labour is advanced, and its nature ascertained. It would be destructive to the lives of the parent and offspring, if the former were so deformed that the latter could not be born without instrumental aid; and yet a writer in one of the periodicals declaims against the remedy, because it did not effect delivery in two cases of highly deformed pelvis. As a general rule, the medicine ought not to be given unless the outlet of the pelvis is unobstructed by bony or soft tumours, and the head or feet of the infant the presenting parts. In a case of placental presentation, to which I was called by Mr. Austin, of Red Lion-street, Clerkenwell, to perform transfusion, I found the lady in a dying condition. I gave her repeated quantities of brandy and the essence of the secale cornutum, as there was no uterine action. She revived, and I proceeded to deliver her by version or turning, having previously explained to her husband that she might die during the operation, or that transfusion might be necessary. I succeeded in bringing down the feet, the brandy and ergot were freely repeated, uterine action came on, the infant was extracted, the placenta was removed, the uterus firmly contracted, there was no hæmorrhage, and the patient did well. The operation was not commenced for some minutes after a double dose of the ergot; and as soon as the head was in the uterus the medicine was repeated. The ordinary dose would have been useless in this case, so prostrate were the vital powers until roused by brandy. The object was to excite uterine action as soon as the head was in the uterus, and was fortunately accomplished. T.]

INTERNALLY. *Powder.* Grs. x—xxx in ℥vi of a proper vehicle.

Decoction and Infusion. Grs. xx—xc, and even more, in Oss of water.

A spoonful should be given every ten minutes.

Decoction of the Ergot of Rye. H. of Germ.

Rx. Secalis cornuti, ℥i;
Aque, Ojss.

Décoque ad Oij et cola cochleare magnum adhibeatur quartâ parte horæ.

Potion Ocytique. H. de Mont.

Rx. Pulv. secalis cornuti, 3i
Liquoris opii, gut. xx;
Syrupi simplicis, ℥iij;
Olei bergamotti, q. s.

Fiat potio cujus sumat cochleare magnum omni semi horâ.

[*Anti-hæmorrhagic Powders.* (Ryan.)

Rx. Secalis cornuti, 3 ss;
 Pulv. cinnam. comp. ℥ss;
 Sacchari purific. 3 ss.

In chartulas x divide, quarum capiat unam, singulis, secundis vel tertiis horis

In active hæmorrhages from the nose, lungs, stomach, bowels, vagina, uterus, and bladder, one of these powders may be given every quarter or half hour, until the bleeding is diminished or suppressed. One three or four times a day will frequently suppress simple leucorrhœa or gleet. In the two last cases, if the medicine fail, I combine it as follows.

Rx. Pulv. secalis cornuti, ℥ij;
 ——— cubebæ, 3 j;
 ——— cinnam. c. 3 ss.
 Sanhari purif. 3 j.

In chartulas viij distribue sumat unam ter quaterve in die.

The essence, liquor, tincture, and decoction may be combined with those of cubebs, buchu, and copaiba added in obstinate cases. T.]

(To be continued).

Rebistering.

The Nature of Cholera Investigated. By John George French, formerly Surgeon to the St. James' Cholera Hospital. Rivington. 1835.

THOUGH cholera has for the present shrouded its death-compelling form in the mists of causality, which medical authors have in vain attempted to penetrate, and no longer comes "to vex the nations," it is by no means a consequence that the inquiries of the physician into the nature of the scourge that *has been*, should relax. On the contrary, we think that now, when the accumulation of facts is so great; now, when the excitement of imminent devastation is past, and coolness allowed to weigh the question in the balances of reason, now is the period for the erection and enunciation of those doctrines for which former experience may have afforded a foundation.

Though therefore, with the many, cholera may have ceased to be matter of reflection, or of vulgar interest, we should not consider that we were doing our duty as journalists were we to pass over either the voluminous monographs or the diminutive brochures on the subject, which spring into print in these "piping times" of safety. This pamphlet of Mr. French is the second on the same

subject published by that gentleman, the former having appeared in 1832. In that he endeavoured to establish that the process which supersedes that of digestion and leads to the secretion and excretion of a vast quantity of fluid from the digestive surface, and thus to an increased viscosity of the blood, rendering its circulation more difficult;—that this process constituted the disease. In the present work he goes on the ground, that in the origin of cholera the heart becomes palsied by the impression of some poison, and that which we commonly call the symptoms of the disease are collectively the salutary efforts of nature to remedy the mischief caused by the incapability of the heart to transmit blood. Thus, if the blood remain fluid, it will continue to pass to the heart, which is incapable of duly transmitting it; nature therefore opens an immense surface, whence the fluid parts of the blood may be poured out, and the latter left in a condition less fit for circulation: by this means time and rest are allowed to the great circulatory muscle to recover itself. But while nature is thus, on the one hand, giving time for recovery to the heart, the act of vomiting is providing that the viscid blood in the vessels shall not be utterly stagnant: vomiting, therefore, besides assisting in carrying off a quantity of fluid, also acts a good part in mechanically propelling the blood, and *gradually*, as the heart recovers, restoring the circulation. "The absence of bile," Mr. French continues, "is owing to its inutility in the process going on, opposed as this last is to the healthy digestion. The urine, too, is scanty, because its constituents are already being carried off by the digestive surface." These are the *pathognomonic* symptoms of cholera, and Mr. French was by no means called upon to account for the thirst, cramps, altered voice, cold surface, oppressed respiration, &c., &c.: these occur in many other diseases, and cholera may kill without many of them.

The result of the above doctrine is a treatment founded on the indications of nature, namely the relief to the heart in the first instance, and the re-liquefaction of the blood in the second. Bleeding answers the first, and dilution with cold water the second—a treatment in the judiciousness of which we perfectly agree with Mr. French.

Such is the sketch of Mr. French's pamphlet. We leave it to our readers to compare its statements with their own experience, and pronounce accordingly.

—o—

Transactions of the Medico-Botanical Society of London, for 1832 and 1833.

THE ten papers which occupy the pages of this publication, each and all contain original and interesting matter. In the first, Dr. Rousseau treats of the medical properties of the holly and ilicine—the latter being the active principle of the former, and extracted from the decoction of the leaves by a process resembling that by which the other vegetable alkalies are obtained. Holly leaves are given in decoction (half an ounce to 8 or 10 oz. of water boiled to one-half, the whole to be taken two hours before the fit); in substance, (one or two drachms macerated in white wine for twelve hours, and taken as the last); in extract, (one-half to one drachm in pill); as ilicine, (in doses of six, eight, eighteen, or twenty-four grains, continued till the disease is subdued); as injection, (one ounce of leaves boiled for a quarter of an hour, in water sufficient for injection). Numerous cases are related, but they do not seem to shew that ilicine may be confidently used as a substitute for quinine.

The "Ancient Plants of Egypt" form a very pleasing article, by M. Bonastie, a corresponding member of the Society.

Not less so is the "Account of the Chiritmanos of Peru, and the Medicines sold by them." These Chiritmanos are travelling doctors, and by birth Indians of Upper Peru, or Bolivia. The writer of the article, W. Bollaert, Esq., says, that the medicines they carry with them do little harm or good, though some may have properties to recommend them, if skilfully administered. The following is a list of most of them and of their uses:—

"*Jaco*: bole, principally of oxide of iron.

"*Salvia*: good for the *ayre*; this is a term for a cold. The substance is either taken in decoction, or the leaves moistened with saliva, and applied to the temples. It is a species of sage.

"*Youruma*: bark of a tree, powdered, and taken as snuff in headach.

"*Piedra Biscal*: this seems to be some inert earthy body: it is directed to be ground, and taken in warm water for the heartburn,

"*Quena Quena*: seeds seemingly of a species of *Annona*: decoction of it used in headachs and tercianas, or agues.

"*Contrayerva*: a species of *Dorstenia*: infusion in water given in pains of the stomach.

"*Chacaire*: given in pains of the sides; powdered, and taken in warm water. This is the excrement of a bird called Coco.

"*Suelda con Suelda*: ground into powder, and then fried in fat, made into plasters for broken bones. It takes its name from the Spanish word *soldar*, to mend or solder.

"*Huachanca*: from a species of *convolvulus*, probably *Jalapa*, is used as a purgative. The dose is marked in the specimen.

"*Corro*, or *Curru*: powdered, and mixed with fat and urine, used to rub the bones when painful. Seems to be the seeds in the seed vessels of a species of the *Helicteres*, or screw tree.

"*Charna*: some little sticks, mixed at times with the above. (It accompanies the foregoing).

"*Venal*: for bad eyes: the leaf is chewed, and the eyes anointed with the saliva. The bad eyes, during the operation, must be placed looking at the sun.

"*Colquemillo*: this is alum; used in itch or pimples on the skin: the parts affected first washed with urine, and then the alum, in fine powder sprinkled over them.

"*Chuuchemuntana*: for heartburn.

"*Ymale*: for jaundice, powdered, and taken in water. Seems to be a species of *Veratrum*.

"*Raiz de la China*, or Chinese root; used in gonorrhœa, likewise when the menses do not flow regularly: given as a decoction.

"*San Juanillo*, or St. John; an agreeable bitter, chewed for toothach.

"*Ointment of St. Peter*: wax, grease, &c. The Chiritmanos say several rare herbs enter into its composition.

"*Aceite de Maria*, or Mary's oil: a small quantity, used as a plaster, applied to the navel of females, during childbirth, to give easy labour.

"*Cebo de Utrunco*: fat of a wild animal called the Utrunco, rubbed round the waist of women in labour: said to facilitate it.

"*Parches*: patches or plasters: these are of various materials, but principally of leaves of favourite plants; sometimes the Coca, Ivy, Venal, &c. These are moistened with saliva, and applied to the temples in headachs, &c. At times some ointments are prepared from the leaves with fat and wax.

"*Charms*: these are of various descriptions, such as the false nutmeg, *Tairuvies*, small red berries; another, a large black seed. These worn, prevent people from colds and coughs. Loadstone, if worn by either sex, ensures the love of those they are attached to; said likewise to attract lovers. Another property is attributed to this substance, that of keeping evil spirits from the wearer. There

are other charms against witches, ghosts, &c.; some against poison likewise.

"Clysters are recommended in cases of stoppage in the bowels, but of such dirty and useless substances that they need not be mentioned here."

The Chiritmanos bleed with a bit of glass fixed into a chip of wood; the operation is performed in a manner something resembling bleeding with a fleam.

Professor Burnett's "Inaugural Address," is an eloquent exposé of the useful purposes of the Society in question, and of the extensive applications of vegetable nature to medicinal purposes.

The last paper, on the "Medical Plants mentioned by Shakspeare," is from the pen of Samuel Rootsey, Esq., and is an "elegant extract" of those passages of our great bard, in which reference is made to botanical emblems of the softer or fiercer passions, or in which natural descriptions of flowers and plants are given, in language such as none but Shakspeare could utter. We dare not attempt to quote one passage as more beautifully appropriate or true than another, in the fear that we should find ourselves gradually and instinctively transferring the whole of them to our pages. Suffice it that we state the whole should be read in the Transactions.

This is a most instructive little volume, and the style is not more prominent than the *dulce* throughout.

The London Medical

AND

Surgical Journal.

Saturday, March 21st, 1835.

CLINICAL INSTRUCTION IN OUR HOSPITALS.

Hæc ego non credam Venusinâ digna lucernâ?

Hæc ego non agitem?

Juvenal, Sat. 1. 51.

We have more than once adverted to the miserable want of true clinical instruction in which the students of our medical schools stand. The remark is more particularly applicable to those who seek their professional education in this metropolis. It may perhaps be thought unnecessary for us to enter into an argument to prove that the fault of

this is altogether attributable to the *professing* teachers of clinique. We may however be pardoned if we shew such to be the case, by merely stating what the student proposes to gain by clinical attendance at the hospitals, and what he actually does gain.

When the period for hospital attendance arrives, the student is presumed to—and indeed according to the regulations issued by the Apothecaries' Company must—have already collected in the store-house of his memory, those practical precepts which the *bonâ fide* experience, and recorded reflections of writers, have enabled him to gather from books, and those which oral lectures have in some degree made more familiar to him; for the impression of a personal communication of facts, though these be more meagre, and the arrangement [of them less perfect, is, nevertheless, made in stronger characters on the intellect, than are the black and white truths of a printed page. But the student looks for, and requires further familiarization with disease. Primed with "book learning," he expects to find in an hospital those numerous opportunities of applying it, which the enormous fee he has paid certainly entitles him to demand. And when we say "apply," we mean the actual, personal comparison of what he has read, with what he sees in the hospital patient. Now this application supposes a free and unlimited audience of all the *professing* teacher addresses to, hears from, and thinks of the patient and his case. That the student should obtain this, the teacher should have the power and willingness to arrange his mode of examination, and to repeat it if necessary to the student; he should possess the very unfashionable patience to listen to the pauper sick man; for though he may be quick-witted enough to understand without hearing the whole of the symptoms, the surrounding students possibly may not; and he should have the reflective strength which shall

draw a sound inference from a train of facts, as also the happy property of communicating it; moreover it should be necessary that the lecture should either be delivered at the bed-side—or that the time of examination should be prolonged, so as to afford the student space to make notes that would assist him in recognising the case when alluded to (if it ever be so), in the distant lecture room. It would be also essential to the student's progress that he should have the opportunity of putting questions, and conveying to the teacher his ideas upon any given case; by this means his thinking propensities would be fostered, and his errors of judgment probably rectified. Were all this granted to the student, as it indubitably ought to be, his clinical instruction would no longer be a mere *vox*, his "walking the hospitals" (the fond phrase of many a fond parent when his son starts for London) a mere lounge, his payment of fees a mere robbery, and his quantum of improvement a mere *nihil*. We should gradually cease to see the grossly bad observers of disease who, never having had the lesson when young how to become so, grow old in the ignorance of their ways, incapable of appreciating, incapable of communicating even the scanty facts that may have been thrust upon them by repetition. But little do these hospital teachers think of or care for the invaluable gift of sound clinical instruction.

Patience and capability are therefore essentially requisite in the clinical teacher. Do we find them in this man, who chooses his own hour for visiting the hospital, whether it suits the student or the patient's disease, or not? In this other, who comes odoriferous and dapper from the boudoir of the nervous lady—and just pops in *en passant* to see how the *people* at the hospital are getting on? In a third, who scorns the student and the patient alike, considering the weight of "hospital physician" to his

name as the only thing about the office worth the having? And lastly, in a fourth,

"Whom *learning's* face ne'er favour'd with a smile,"

and who, without half an idea in his own possession, cannot, by rule of arithmetic, give one to his pupils? The Gazette has challenged the exclaimers against the hospitals to point out individuals and instances in confirmation of their assertions and opinions; *it were easy to do this*; but the Gazette knows well that there is a libel-law which makes the publication of the greater truth the greater libel, and not improbably the very writer of the challenge in question would be one on whom we should fall foul, and who in return would fall foul on us with this law in his hand. *Au reste*, let the Gazette or any other stickler for luxuriant abuse endeavour to find in the traits of the four characters above included in as many notes of interrogation, the counterparts of some of our hospital physicians.

But to return; patience and capability as displayed in the details already mentioned, are the requisites for a clinical teacher who shall do justice to the clinical student. "But," we hear some one say, "if all this were required and enforced, who would be an hospital physician?" In like spirit did the first prelate of the realm maintain that if bishoprics were reduced to a sum under £4,500, no *gentleman* would have the ambition to undertake them. Fortunately in neither case do we want *gentlemen* in the *pecuniary* weight of the term, and the *idle* acceptance of the office; we want none of the "*fruges consumere nati*" for what should be posts of activity. For ourselves, we have no alarms on the subject, and are perfectly ready to leave such a dreadful contingency to Providence, in the certainty that physicians able to undertake the *active* duties of clinical teachers, are a genus the species of which will

never fail. In enforcing the attention of the physician to the patients and the students, you do nothing that degrades him, and therefore nothing that should prevent one of gentleman-like habits and education from accepting the office. On the contrary, it would be hard to find any thing more low, contemptible, and ungentleman-like, than the acceptance of an office, and the duties of it, without any previous intention or subsequent willingness to perform them. Away then with the stuff and nonsense about professional degradation.

There are two ways of remedying the evil we denounce; one is by operating on the teachers, through the medium of those who elect them; the second by operating on them through the medium of those whom they profess to teach. The former would be the preferable mode, and therefore—so well is the whole system of hospitals arranged—the least practicable. Nothing would be more effectual in bringing their honorary officers to order, than the exercise, on the part of the governors, trustees, or whatever else they may be, of the hospitals, of judgment and mature reflection in their choice; and after choosing them, to enforce conditions having reference to the patients and the students, conditions on the fulfilment of which their tenure of the office should depend. It is true that the tenure at present is nominally *dum bene se gesserit*; but who is to judge of the *bene*? The governors, &c. do not please to interfere. And this leads us to the second mode or remedy.

We say then let the students sit in judgment on their clinical teachers; let them weigh their capabilities with their own educational wants; let them be swayed by no choice of locality, no predilection for this or that end of the town in their election of clinical teachers; let them patronise those who patronise them, who consider their progress of some consequence (for none

that we know consider it of *great* consequence), and who are therefore comparatively the most worthy to receive their money. Were this system of exclusive dealing acted upon, we might still hope for some amelioration in the condition of the fleeced student, and some improvement in the manners of the fleecing hospital physicians.

—o—

On the Various Modes of applying Water, and the Beneficial Results to be Derived from its Use in Surgical Practice.

To the Editor of the Original London Medical and Surgical Journal.

SIR—I am induced to offer a few observations, through the medium of your valuable Journal, on the above subject, in consequence of having seen an application called *water dressing*, made use of at the hospital attached to the London University, by the justly celebrated and scientific surgeon, Mr. Liston. I have used it for many years in my own practice, and have every reason to prefer it to any other mode of surgical treatment: indeed, in many cases which I could relate, the reparative process under the influence of its application, has been so much greater than we usually observe, that in less enlightened times it might be deemed as bordering on the miraculous. The knowledge of the therapeutic effects of water, the principles on which it should be applied, and the different ways of applying it, I obtained from the precepts and practice of Dr. Macartney, when at Trinity College, Dublin. Having met but few who are aware of the benefits to be derived from its use, I am naturally desirous to communicate a sketch of its history and properties—short, indeed, but, I trust, sufficiently intelligible and emphatic to induce my brother practitioners to try it, and convince themselves, by the essay, that it is deserving of their—as I have found it of my—preference.

I remain,

Your obedient Servant,

JAMES WILSON.

1, Kingsland Road.

The application of water as a remedy, both locally and generally, together with the miraculous cures resulting from its use, is of very ancient date. It is said to have been used at the siege of Troy by Patroclus, and throughout Greece by the Priests of Æsculapius. Hippocrates also habitually used water as a local remedy, his mode of application being a wet sponge constantly laid to the part. It was probably the mere physical effects of water that were exercised in the cure of Nahaman the Syrian, when he was ordered by the prophet Elias to go and wash seven times in Jordan. Among

the Arabians water was a most frequent remedy; but previous to being used, it was charmed by the immersion in it of their prophet Mahomet. (Might this usage have given to Scott the idea of the talisman which he makes the Hakim introduce into the cup of "what appeared to be pure spring water?") Ambrose Paré inquired into the advantages to be derived from the use of water, and tried it at the Hôtel Dieu: but he did not continue its use, and for a curious reason. Paré was a most pious and, unfortunately, superstitious man. Thus when he discovered the use of the ligature, he considered it sufficiently wonderful to be called a revelation specially made to himself. Thus, too, when beholding the wonderful cures effected by water, he deemed it nothing less than a miraculous remedy, and, consequently, unlawful for mortals to deal withal: he, therefore, abandoned the use of it! In more recent times, Baron Larrey used it while in Egypt: he was induced to do so from hearing that the water of the Nile was blessed with curative virtues—so prone are we to the wonderful, so unwilling to believe that great effects can proceed from simple causes!

These facts shew that water is a very ancient remedy. Acting as it did, or was supposed to do, under the secretly benign influence of some charm or priestly blessing, it, no doubt, produced benefit by the double impression on the mind and the body. But reason may teach us that the happy results could not have been so frequently obtained, or to such extent, as if it had been accompanied with a knowledge of the principles of its application, and more or less acquaintance with its *modus operandi*. To these principles, and to this *modus*, I shall now address myself.

In surgical dressing, by this method, a piece of fine lint is to be moistened in water and applied in a double fold, so as completely to cover the affected part. Over this a piece of oiled silk, somewhat larger than the lint, is to be placed. The lint will, of course, require to be changed occasionally, otherwise the secretion of the part will become mixed with the application, and prove, in many cases, irritating and hurtful. The oiled silk is essential, in order to the prevention of the evaporation of the water, and, by the retention of a vapour, to the maintenance of the parts in a state of moisture and in an uniform temperature.

It may be said that these indications are fulfilled by a warm poultice; and it is so far correct to say, that nothing but the vapour from it is beneficial in effect: for the bread, flour, or meal, as it may be, is only useful in holding or detaining the water and its vapour. But, on the other hand, we have the inconveniences of its size and weight, together with the tendency to decomposition after any lengthened application—circumstances which certainly withdraw from its

utility, if they do not actually render it an irritant to the part. Every one is well aware how much the nature of a poultice is changed after being kept for a whole night on a diseased part. Now these disadvantages are, in a great measure, avoided by the water-dressing, which, moreover, possesses the advantages of simplicity, cleanliness, &c.

With regard to the principles on which the application of water-dressing is made, they are referable to the removal of the affected parts from all external impressions, and to place in the most pleasing situation, that is, to the production of that state where the sense of injury is diminished, and to the withdrawing of every thing that can interfere with the operations and endeavours of nature towards a cure. The temperature being always equal, and every source of restraint and external irritation absent, the disposition in the body violently to resist all sudden changes, and to become irritable under sense of injury, is diminished. To shew this, it is only necessary to recal the fact, that the arteries always sympathise with the sentient extremities of the nerves, and that impressions primarily made on the latter are transmitted to the former.

Granulations will spring up in chronic ulcers, under the application of water-dressing, or warm steam, when other means have failed; should the granulations be too luxuriant, the removal of the oiled silk will suffice to reduce them without the aid of an escharotic. *Cicatrizatio*n quickly takes place, and is never followed by a morbid cicatrix. In such cases the water may be used at various temperatures, the sensibility of the part soon choosing that which best agrees with it.

In recent wounds cold water is useful in restraining hæmorrhage, and preventing the occurrence of inflammation, and this more particularly in cases where there is not much injury to sensibility, and when reaction is to be moderated; for it should be remembered that irritation ever interferes with the reparative process: it is by allaying such irritation that the gradually warmed vapour acts. The application to piles of a piece of sponge moistened in water and covered with oiled silk, produces a soothing effect, which no one would credit who had not experienced or observed it. Wounds of all kinds are also benefited by water of various temperatures, and the inflammation and suppuration—processes very hurtful to the act of healing, though vulgarly considered necessary to that act—restrained.

On a future occasion I hope to pursue this subject, and to illustrate it with some cases.

Hospital Reports.

NORTH LONDON HOSPITAL.

New Instrument for Stammering.

DR. ELLIOTSON made some remarks, on Thursday last, on stammering. He said that there were various opinions as to the seat of the disease—some supposing the muscles of the glottis to be affected, others the muscles of the tongue. Dr. Bostock published a case in one of the journals, some years since, which he had cured by purgatives: this was most probably a case depending on a fulness of blood in the head, or disorder of the digestive function—some gentleman had cured the disease by giving the persons more confidence in themselves, and instructing them to take a true inspiration before speaking, and to speak deliberately; there is no doubt the mind has great influence on the muscles connected with articulation, as well as the other muscles of the body. In St. Peter's Dance, if you come suddenly near a patient, so as to take him by surprise, the symptoms are aggravated, and the emotions of the mind act on the speech in something of the same manner. The Doctor then introduced to the class a youth who had been treated for this disease in a novel manner by a Mr. Metz.

It appeared that Mr. Metz had befriended a Polish gentleman, who had since gone to America; previously to his going, he wished to repay Mr. M. in some way for his kindness, and presented him with a small silver instrument, which he said had proved a great source of profit and fame to him on the continent, as it had cured a great number of persons of stammering. This instrument, acting as a support to the tongue, kept it steady. The instrument being hung to the teeth by means of three hooks, prevent it from moving about. When Dr. E. first heard of the instrument, he was inclined to treat it as a piece of nonsense, but when he was informed of the principle on which it acted, he thought the plan good, and worthy of a trial. He instanced the circumstance of resting one foot on the toe whilst sitting, being attended with a tremulous motion of the limb; but place the whole foot on the ground and the limb becomes firm and steady; it was reflecting on this fact that led him to think the principle a good one; but he believed there were other muscles besides those of the tongue concerned in impediment of speech. Dr. Arnott, in his *Elements of Physics*, had mentioned that the muscles of the glottis were agitated in a case he saw—therefore one mechanical remedy would not be applicable in all cases.

The youth present, on whom Mr. Metz had tried the instrument with so much benefit, had stuttered from the age of six years—he is now fourteen. He was always

at home with his father, who also stuttered. Dr. Elliotson remarked, that stuttering is a hereditary disease, coming on at a certain time of life, in the same manner as gout, epilepsy, &c. The instrument had been applied for seven weeks past, but, in consequence of the youth being at a boarding-school, Mr. Metz says he was much neglected, and only practised the remedy two hours a day. The patient now read a passage from a newspaper without the instrument being applied—he stuttered considerably: he afterwards read with the instrument—the difference was not, however, very decided, though, on the whole, he read better. Dr. E. said he could not decide on the merits of the instrument until he had seen more of it. Mr. Metz agreed to bring his patient again in three weeks' time.

Dr. E. then referred to the case of James Davis, 50, who is at present under treatment for periostitis. The patient, on his admission to the hospital in the beginning of February, had great pain and swelling of the periosteum in different parts of the body: the pain and redness increased always towards night: being syphilitic, mercury was administered until the gums were slightly affected: the symptoms remained the same, except that the pains at night ceased. The hydriodate of potash was now given in small quantities, of a solution containing 3i of the hydriodate to ʒi of distilled water. He took ʒss doses twice or thrice a day: in two or three days the dose was increased to ʒij. He has continued this since the 14th of February, and is now quite recovered: the effect was very decisive, even in three days. Dr. E. had seen his medicine very advantageously employed in cases of indurated lungs with effusion; he had seen quarts of serum removed, and the organs again become healthy. He had employed it in the case of James Reids, 45, now in the hospital, on his admission on the 12th of December last. He had extreme difficulty of breathing, swelling of the legs, and scanty high-coloured urine; inability to lie down, and was obliged to be supported by pillows in nearly an upright position. Dr. E. was led to believe the lungs in this case were solidified, from his not being able to hear any respiratory murmur at the roots of the lungs near the spine. Laennec says, in cases where there is only water in the pleura, you can. In this case there was some fluid; he heard egophony, which he could not have heard had the chest been quite full; therefore, in cases where you hear this sound the chest does not contain a large quantity of water. In this instance there was effusion into the cellular membrane of all the limbs and abdomen: being too weak for bleeding, the H. of P. was given to him, with other diuretics; this, however, seemed to do no good; the hydriodate of potash was persevered in, and the man is fast recovering; and, instead of

wearing the gloomy looks he lately did on the approach of the doctor, as if he thought himself beyond the power of medicine, he is now the Joe Miller of the ward. The medicine was assisted by letting off the fluid mechanically, as diuretics then act more powerfully. Dr. E. had never seen danger from acupuncture of the thighs—you may make a dozen openings there—but there is always danger below the knee. He has often punctured the external parts of generation—there is no danger in such a proceeding—you can puncture every day if the water ceases to flow, but generally there is a discharge kept up for several days. He should also state, that in the arm he never practises acupuncture below the elbow.

The patient above had an ointment composed of the following, rubbed on the abdominal parietes:—

Iodine, \mathfrak{J} i; Cerat. \mathfrak{z} i.

As much as \mathfrak{J} ivss of the hydriodate of potash mixture had been given at once, but as it disagreed with the stomach it was diminished to \mathfrak{J} ii. This medicine may be given to a large extent, but the smaller the doses the better, if effectual. If it purges, you can give astringents and opium; or if purging continues, and it affects the hydriodate, diminish the dose.

It is curious that some persons cannot take two drops of this medicine, while others can take a very large quantity. Dr. E. had seen it of benefit in paralysis and inflammation of the neurilema.

Foreign Medicine.

Vicarious Menstruation by the Lungs.

N——, aged 32 years, fell into a pond, two years ago, when menstruating; the menses were immediately suppressed, and a copious hæmoptysis supplied the place of them, and became strictly periodical. Fifteen months ago she became pregnant, and during the whole of her pregnancy, during her confinement, and all the time of suckling, no spitting of blood occurred; but immediately on her weaning the child it returned.—*Hufeland's Journal der Practischen Heilkunde.*

Preserved Milk—Lactoline.

M. Grimaud has lately succeeded in making a preparation which he calls *lactoline*, and which, mixed with nine-tenths of water, produces the precise composition of fresh milk, the flavour of which it also has. He says it may be preserved for an indefinite period without undergoing change from humidity or heat.

M. Grimaud further observes that M. Braconnot had already endeavoured to make a conserve of milk, in which the latter was reduced to a sixth of its volume; but his process, which is grounded on the coagulation

of milk by acids, on the one hand deprives the milk of the major part of its salts, and among these of the sugar of milk, whilst on the other hand it adds a quantity of sub-carbonate of potass in order to render the coagulum soluble. Such a preparation in this manner is found to differ exceedingly from milk, nor does it retain the flavour of it.

The new mode of preparation is due to M. Gallais, a chocolate manufacturer. It consists in withdrawing the aqueous parts of the milk by evaporation—not with heat, for some change always takes place, let the fire be ever so carefully managed—but by exposing, by successive agitations, all the fluids to cold air.

M. Grimaud also ascertained that the globules of milk still remained unchanged in lactoline. “Hitherto,” he concludes, “milk has only given origin to butter and cheese; but lactoline constitutes a third product, at once pleasant and wholesome.”—*Gazette Médicale*

Fœtus vomited by a Child Three Years Old.

Joannes Vouros, physician in chief of the department of the Cyclades, (Greece), in a letter addressed to M. Poulo, and which the latter translated to the Académie des Sciences at one of its recent sittings, relates that he lately met with a male child, three years and a half old, who had for some time been labouring under worm fever. In the night of the 26th of October, 1834, after several fits of vomiting, the boy at length ejected a human embryo: that it was one, M. Vouros is certain, and the police, who suspected some fraud, were invited to inspect and make inquiries concerning it, which ended in their conviction of the fact.

After M. Poulo, had read the above letter, M. Geoffroy Saint-Hilaire communicated the following circumstance. M. Giraudet, a medical man of Cusset, near Vichy, observed a similar case in the month of June last. “I happened to be on the spot,” says M. G. Saint-Hilaire, “and immediately inspected the vomited mass, and after preserving it in spirits, I subsequently examined it with M. Milne Edwards; it proved to be an abortion without any marked specific organs.”—*Gazette Médicale, February.*

Relative Weights of sound and diseased Bones.

In all phlegmasiæ of the medulla of the bones the latter in a short time lose in weight, by the predominance of the organic matter over the earthy; and the thickness of the bony varieties of the medullary canal diminishes by one, or three quarters of, a line. The compact substance seems to become spongy, and when the inflammation has run its course, the spongy substance of the extremity of the bone has itself disappeared in a greater or smaller degree. If the bones are emptied of the marrow and dried, the continuous medul-

lary cavity causes them to bear some resemblance to the leg bones of those large birds that walk more than they fly. M. Dubreuil (*Journ. Hebd. Nov. 1834*), has made some curious experiments on this diminution in the weight of diseased bones. In four individuals who had died at various periods of time after amputation of the thigh, he weighed portions of the diseased femur—six or eight inches long—and similar quantities of sound femur, sawed off at the same height of the bone. He found the first diseased femur to weigh four ounces, two drachms; the sound, eleven ounces, four drachms: the second diseased piece, six ounces; the sound, twelve ounces four drachms: the third diseased, four ounces, two drachms; sound, eleven ounces, six drachms: the fourth diseased, seven ounces, two drachms; sound, eleven ounces, two drachms. This diminution of weight is sometimes exceeded; in a case of *fragilitas ossium*, Saillant relates that the patient floated in the bath, and that two persons were required to keep the body under the water.

It is worthy of remark, that these pathological phenomena are the exact representation of the state commonly regarded as that of old mens' bones. The remark had been made by M. Malgaigne in reference to the inflammation of the spongy tissue of bones; but M. Dubreuil is the first who has marked this analogy in reference to the dicophysis and the long medullary canals. He was at first inclined to consider these alterations as the consequences of phlebitis or arteritis. M. Blandin says he found the veins of the marrow affected with phlebitis in six instances; but M. Dubreuil's researches into medullary inflammation of the bones, do not lead him to coincide in this opinion.—*Journ. Hebdomadaire*.

Erectile Tumour with a Bony Nucleus.

M. Lisfranc lately shewed the Academie de Medecine an erectile tumour, which he had taken from a young man twenty-four years old. It had only been two months in growing, was situated on the face, and was only the size of the tip of the little finger. But what rendered it remarkable was, that it included a concretion of the size of a hemp-seed, and was bony in nature. The tumour was seated altogether in the cellular tissue.

M. Lisfranc incidentally remarked, that, in operating on nævi, unless at least two lines of the surrounding sound tissue was taken away, the nævus almost always re-appeared in the cicatrix, in part or altogether. He applies the same principle to all erectile tumours, unless the locality fails to allow of it.

Opium and Saliva.

M. Texier, in his late account of the culture and gathering of opium, addressed to the Academie de Medecine, (March 3rd, 1835), says, that after the flowing of the poppy juice and some evaporation, it appears as a grumous and glutinous jelly, which is placed in earthen vessels: *it is then pounded with spittle*. M. Texier asked them, why they did not take the trouble of using water: they answered, that it would spoil the product!!

Dupuytren's Pommade to prevent Hair from falling.

Macerate a drachm of powdered cantharides in an ounce of spirits of wine, and filter. Take ten parts of this tincture and rub it in a mortar with ninety-parts of cold lard.

Death of Foderè.

This celebrated medical jurist and learned writer on epidemics, died at Strasbourg in the middle of last month.

LECTURES
ON
MEDICAL JURISPRUDENCE,
DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,
At the University of London; Session 1834-35.
LECTURE XXII.

GENTLEMEN—A frequent consequence of melancholia is *dementia*, or fatuity. It is difficult to distinguish it from *amentia*, imbecility, or idiotism; and yet, in a medico-legal point of view, this is a matter of much consequence, as *dementia* implies that the person may have been at one time sane, or may again become so, whereas *idiotcy*, strictly speaking, is a congenital disease, and no hope of improvement or change is anticipated. When epilepsy attends insanity, fatuity is a frequent result of a continuance of the disease. In fatuity, a man may be so managed as to act with regularity like a piece of machinery, and this may mislead careless observers, and appear as if the consequence of reasoning; so that much care is requisite to avoid fallacious opinions being formed. It requires the medical man who is to give an opinion on the state of the person to see him very frequently, and to vary the hours of his visits; for, although a person labouring under *dementia* is usually calm and quiet, yet, short periods of irascibility and fury intervene, which may be observed by frequently varying the time of visiting the patient. Attention must also be paid to ascertain whether any indications of hatred of particular individuals is obvious; as this is very characteristic of this morbid state, and no kindness in those on whom their dislike falls can ever lessen or change it. In *dementia* the habits of cleanliness are lost, and the greatest beaux and belles become slovens; and the appetite is generally increased to a degree almost approaching to brutality; in which case, however, the patient does not always get fat; on the contrary, emaciation is often in the ratio of the voraciousness of the appetite. In whichever state the patient appears, the countenance has a peculiar character—a

vacant inexpressive look, which is readily recognized: in general the face is pale, the eye dull and moist, and the pupils are dilated. It is a curious fact, that the greatest number of deaths which occur in insanity is after fatuity makes its appearance.

As such a state of mind renders a person as incapable of managing his affairs, and as open to mischief as insanity, legal means are necessarily taken to protect them; and such cases are generally put under the jurisdiction of the Court of Chancery, when property is concerned, to protect the individuals from the cupidity of relatives and others. The justice and expediency of such a power to protect the persons and property of those who are incapable of taking care of themselves, must be admitted. In determining the necessity, therefore, for the interference of the Lord Chancellor, it is to the medical attendant that the law looks for the detection, exposure, and defeat of frauds; and, in such cases, depending upon the profession, it is a sacred duty to have a perfect knowledge of the disease.

The state with which *dementia* is most likely to be confounded is, undoubtedly, *idiotism*; let us, therefore, briefly examine the nature of this state. *Idiotcy* was formerly employed as a term to signify an unlearned or ignorant person; but in the English law it signifies a person who has been without understanding from his birth. Considerable latitude has been given to the term, as Lord Coke includes in it a person who is born deaf, dumb, and blind. The following is the legal definition of *idiotcy*: "*Idiotæ sunt illi tantum, qui omni ratiocinatione et judicio cavent, tardi, bardi, moreones, macærones, qui inopiâ caloris et spiritum laborant.*" Those are accounted idiots who are devoid of reason and judgment, stupid, lumpish, fools, who labour under a defect of heat and spirits. But, in a physiological point of view, *idiotcy* may be either congenital or *à nativitate*, or it may result from accidental causes, as, for instance, diseased organization of the brain, arising from long continued epilepsy, intemperance, or depressing passions; in which case it, as it were, amalgamates with fatuity, and only differs from it in termination. Congenital

idiotcy is the most frequent form of the affection, and is generally connected with, or dependent upon, some faulty conformation of the bones of the head, and organic affection of the brain and nerves. In congenital idiotcy, the physiognomical characters of this state are almost, in every instance, sufficient to enable us to pronounce judgment upon it. There is a vague, unsteady, wandering eye; at least the eye is seldom fixed for any length of time upon any one object; a stupid expression of countenance, which portrays no sign of intelligence, and the face disproportionately large, compared with the head; the mouth is generally gaping, and pouring out saliva; there is a perpetual rolling and tossing of the head; no memory, no language, no reason. Some, however, among the Cretins, in the Valais, in Switzerland, and among the inhabitants of Carinthia, where idiotism is very prevalent, are not altogether dumb, but express themselves in inarticulate sounds, cries, or in prolonged roars. These poor wretches, and idiots in general, have all the animal instincts, and some of the passions; but their joy is unmeaning mirth; their fear a tranquil quail; their anger a momentary fit of violence; the gratifications of appetite are their only pleasure; bodily pain, or the dread of it, their only sources of anger. It is said that idiots have strong sexual desires, and great powers to execute them, but I apprehend this assertion is, at least, doubtful; it is certain, that persons who become fatuous have seldom any sexual appetites.

In an instance of a girl, twelve years old, mentioned by Esquirol, the head was large and irregularly shaped, and the forehead high and prominent, so that the facial angle was more than ninety degrees. She ate voraciously and without discrimination; passed all evacuations involuntarily; but the menses were regular and abundant. In her walking, and in every movement, she was a helpless infant, insensible to every change of temperature, to rain, and even to her own internal feelings. She could only utter the words, *papa—mamma*, which she frequently repeated. Another remarkable instance is mentioned in Mr. Hobhouse's Travels in Albania; the idiot was a female, about three feet and a half in height. She constantly sat rolled up, as it were, upon a truss of straw: she was quite dumb, nearly deaf, and was possessed of no one consciousness of humanity. She would hop towards her keeper, on being loudly called by a name with which she was familiar.

But all idiots are not so remarkable as these: some possess a certain degree of memory, and display certain powers of imitation, and repeat passages from books which they have been taught, but are incapable of comprehending what they repeat. I have even known instances in which a witty reply has been delivered by a person in every other respect an idiot. A learned Professor

in Edinburgh, once accosting a half idiot, asked him how long he thought that a man could live without brains; the poor fellow, before replying, looked the questioner full in the face, and then laying hold of the lapel of his coat, said, "Pray, doctor, how lang hae ye leeved?"

The brain, and the bones of the cranium, are both unnatural, in point of conformation, in this very humiliating state of humanity. The nervous system is so much deranged, that life can with difficulty be maintained; and therefore idiots seldom live to the age of thirty, and generally die either in an epileptic or paralytic state. Meckel, however, mentions an instance of one who lived to the age of fifty-nine. Hydrothorax is a very common termination of mania, melancholia, and idiotcy; so, also, is phthisis; and in post mortem examinations it is of great importance to distinguish between the effects of those diseases on the brain, and those of mental alienation. Even when the disease is not congenital, the causes which produce it derange the texture of the brain; and the medium of the sensorial impression, that by which the communication between the mind and the external world can only be maintained, being rendered unfit to perform its functions, all the operations of mind are destroyed. Besides idiotism, it is necessary that you should also be aware that insanity occurs also *à nativitate*, and even in cases where neither parent display any symptoms of lunacy. [The lecturer here gave the case of a mad child.] This case is so exactly similar to one related by Dr. Haslam, that I cannot do better than read it to you. (Vide Haslam's Obs. on Madness, p. 198.) Lorry also mentions a child who was born mad; and for the short period that he lived, for he died during dentition, he tore and destroyed every thing.

When idiotism does not proceed to the utmost extent, questions may arise in which it is essential to determine the capacity of the person.

Although the law objects to contracts of marriage made during madness, yet it admits the validity of a marriage contracted with an idiot, *à nativitate*; and the wife of an idiot is entitled to dower. All idiots and lunatics are under the guardianship of the crown, in consequence of a statute made in the reign of Edward the First. In the subsequent reign it became a part of the prerogative of the crown. The king is entitled to the custody of the person of an idiot during life, and has a beneficial interest in his freehold lands. This has always been regarded as a hardship on private families; and, although there are few instances of its oppressive exercise, yet, the responsibility in determining idiotcy is great.

To ascertain the existence of idiotcy Dr. Haslam judiciously advises, as the first step, to examine and endeavour to estimate the power of the idiot's attention; for both me-

memory and his knowledge of objects must be regulated by, and solely depend on, the duration and extent of his attention. If he cannot comprehend the nature of numbers, it is impossible he can have any idea of the nature of property: yet, I have heard of a person who was not accounted an idiot, and yet could not comprehend the nature of numbers beyond four. "If a person," says Dr. Haslam, "is capable of enumerating progressively to ten, and knows the force and value of the separate units, he may be pronounced fully adequate to the management of property: if he can comprehend that twice two compose four, he can find no difficulty in understanding that twice ten constitute twenty; or that so many taken from or subtracted from ten, would leave so many as the remainder. Without such capacity," says Dr. Haslam, "no man, in my opinion, could understand the nature of property, which is represented by pounds, shillings, and pence." A person in this state is competent to make a will; but an idiot cannot make a will; an insane person, during a lucid interval, may make a will; and should he become insane after making a will, at this period, the subsequent lunacy does not operate as the revocation of a will. A petition for a commission of lunacy was preferred against Lord Donegal, in the year 1731, on the ground of the weakness of his understanding. A caveat having been entered, Lord Harwicke, who was the then Lord Chancellor, ordered an examination. In this case it was found that Lord Donegal could give rational answers about his estate; but not to any questions about figures, as to which he could not answer the most common. Lord Harwicke did not think that a sufficient reason for granting a commission. It may be necessary to inform you, that a commission of lunacy is a writ under the great seal, directing a certain number of commissioners, with a jury of twelve men, to inquire on oath whether the person be an idiot, a lunatic, or non compos: in all of which states a person is regarded incapable of making a will. Persons who are idiots or natural fools, persons imbecile from old age, or from disease, habitual drunkards, those labouring under *delirium tremens*, *phrenitis*, and those in *typhus* fever, are regarded as, also, legally incapable of disposing of property by will. It is on this account that the law guards so jealously the property of lunatics; and it is on this account that lunacy is often imputed when it does not exist. "I knew an instance," says Mr. Bakewell, "of a person of very respectable family, who became insane soon after giving birth to a son. She was put into a back garret, where she was coarsely fed and coarsely clothed, while her husband enjoyed every luxury which money could purchase, in the house below, until the son became of age, and had her released." Instances are also recorded in which sons have imputed

insanity to their fathers, brothers to brothers, and even mothers to sons, solely for the sake of property. Persons subject to insanity are incapable of disposing by will during their insanity, although a will made by such person, previous to insanity, is not revoked by the circumstance of subsequent insanity, or by an attempt to obliterate it during a fit of insanity: thence the importance of substantiating these states. Such abuses, when inquired into, cannot be decided without the aid of medical evidence. The law admits of the disposal of property, however, during a lucid interval: a will made in a clear lucid interval will be held valid.

Another reason for inquiring closely into cases of lunacy and idiotism is, the plea which is often set upon this point in bar of execution. If idiotcy be proved, the prisoner must be discharged the indictment, and placed in safe custody; if a lunatic, the same is the case, unless it be proved that he is in a lucid interval; if, also, it be proved that he was actually insane when the crime was committed, then he must be discharged. Before shewing in what manner such inquiries should be conducted, and examining the grounds for granting certificates to confine lunatics, it is necessary to take some notice of the meaning of the term *lucid interval*. To do a sensible act is not a lucid interval. (Collinson, p. 43). By this term is not meant a simple remission of the malady, but a total suspension of it—a complete, although temporary, restoration of reason. The law on this head is explicit—"It is not enough to shew that the act was *actus sapienti conveniens*, for that may happen many ways; but it must be proved to be *actus sapientis*, and to proceed from judgment and deliberation, else the presumption continues." (Hargrave's Coke on Littleton, p. 246, b. n. 1). The law always regards the possibility of a lunatic to recover his senses, at least per intervalla; but these intervals, or lucid intervals, are not mere intermissions of the violent symptoms of the disease, nor a cooler moment, an abatement of pain or violence, relaxation from a higher state of torture, nor the relief of a mind from excessive oppression: it is that space in which the mind, having thrown off the disease, has recovered its general habit. It is not necessary, however, that the mind should have recovered its pristine strength and vigour, to constitute a lucid interval; but it is essential that the party may be equal to the conduct of the common affairs of life, and that ordinary people should think him so. The term is, therefore, relative, but the recovery must be at the time complete. The ascertaining this point is, perhaps, one of the most difficult connected with insanity, in order to arrive at a safe conclusion; for often lunatics are sufficiently cunning to carry on a plan, and succeed in imposing upon their attendants. In determining, therefore, on the actual ex-

istence of a lucid interval, the examinations of the physician should be frequently repeated, and the conduct of the lunatic closely investigated in every state in which he can be placed. In many instances, an insane person will so frame his conversation and behaviour, as to appear in perfect possession of his reasoning faculties; but, if the discourse be protracted and varied, the subject, which is the disordered point in the madman's understanding, being brought forward, the presence of the disease will soon manifest itself, and the individual in conversation with the supposed sane man be soon convinced of the hastiness of his decision. Sometimes, however, the mind of the lunatic is aware of the point of insanity, and evades questions which lead to display it. There is an intermittent species of lunacy, also, in which the paroxysm returns at stated intervals, generally once, twice, or three times a year, and lasts several weeks, the subject of the hallucination being almost always the same; in this case a person is considered quite capable of managing his affairs. The whole life of Cowper the poet consisted of a series of lucid intervals and paroxysms of insanity. The celebrated poem of Lucretius "*De Rerum Natura*," was written during the lucid intervals of intermittent insanity. The existence of this state may be discovered in various ways; one symptom, almost conclusive of a lucid interval, is the acknowledged consciousness of the patient of having laboured under false ideas, when the subject on which his insanity hinged becomes the matter of conversation. But for legal purposes this must be clear and perfect; and it is only under such circumstances that any disposition of property can take place. On equally sound principles, every person making a will is presumed of sound mind, until the contrary be proved, and this proof must rest chiefly on the opinion of medical witnesses; for a will may contain the utmost propriety of its provisions, and yet constitute no conclusive evidence of the sanity of the testator, as Collinson remarks; the testator may have acted reasonably by accident, or the will may have been the production of another. An old man, in his second childhood, who cannot remember his name; a paralytic, reduced to such a state; or one whom excessive continued intoxication has deprived of the use of his understanding and reason, cannot make a will. But a man of weak understanding, between a wise man and a fool, is not disabled from making a will. All these points are determined chiefly by medical evidence; and much discretion is requisite in the medical witness; for high reputation and celebrity in the profession will not enhance the value of evidence before an English judge, if the case be not clear (See case of *White v. Wilson*, Coll. Treat. p. 626).

Besides being called upon to determine the condition of persons supposed to be in-

sane, medical men are frequently requested to give an opinion respecting the probable issue of the disease—whether, in placing the property of the insane persons in the hands of trustees, the means to be adopted are to be regarded of a temporary or permanent description. Under these circumstances it is of much importance to ascertain the extent of recoveries which have taken place—the sex, age, and other circumstances which impede or favour so desirable an event. In respect to the number of recoveries, as stated in tables of the admissions and recoveries, in the great public hospitals in this country, we find that the proportion of recoveries have been as $2\frac{3}{4}$ in 5: on the continent they have been scarcely more than 2 in 4: the prospect of recovery is greatest in young persons, few lunatics having been cured after sixty years of age. With respect to sex, lunacy is more frequent in females than males; but in this country, where the education of females is directed to strengthen the mind, rather than to cultivate the imagination, this difference between the liability of the sexes is much less striking than in other European countries. In France, for example, M. Pinel calculated, in 1802, that there were two female lunatics for every male: in Bethlem Hospital, in the course of 46 years, 8,874 lunatics were admitted, of whom, Dr. Haslam informs us, 4,832 were females, and 4,042 males—nearly 1-5th more of females than males. Something, also, depends on the condition of the patients—thus *celibacy* seems to favour insanity; out of 1,726 female lunatics, 980 were single women, 397 married women, and 291 widows—out of 764 males, 402 were single, 201 married, and 59 widowers. The fact of the person having been previously attacked, and whether the intervals are shortening or extending, should also influence our prognosis: at the same time we should bear in recollection that many persons, after repeated attacks of the disease, have been permanently cured. Education and the premature development, as well as an overstrained exercise, of the mental faculties are often exciting causes of insanity, and also influence greatly its progress and tendency to recovery. In uncivilized nations madness is comparatively rare; it is rarely, according to Humboldt, found among the native Americans; in Russia and Turkey it is rare; and M. Desgenettes found only 14 lunatics in a population of 300,000 people in Grand Cairo. All of these circumstances, therefore, must be inquired into in forming our opinion as to the necessity of confinement of lunatics, and the probability of their recovery.

One of the most responsible duties which devolves upon a medical man, and one which he labours to exercise with the greatest caution, is the granting certificates for the confinement of insane patients. It is one, also, which is properly looked upon

with great jealousy by the public; and when judiciously exercised, should elevate the profession above all suspicion of prejudice, erroneous bias, or connivance.

There can be only one opinion respecting the propriety of separating the insane from their families and from society. It is only by doing so that old associations can be broken, and new sensations impressed upon the mind: besides, experience has demonstrated that a separation of this kind is invariably followed by a remission of the complaint. Amongst his friends, the maniac sees only misery, vexation, and enemies; every thing around him contributes to confirm the erroneous judgments which influence his conduct; whilst, on the other hand, the presence of strangers almost always suspends the delirium of the insane, and aids the influence of new impressions, which is always useful. Such being the case, the only circumstance necessary for your consideration is to determine the truth of the insanity, and the advantages to be obtained in each particular case by a removal from friends, and confinement in a lunatic asylum. Friends are always repugnant to acquiesce in this part of the plan of treatment, and individuals are always at hand to throw blame upon the practitioner who advises such a step; and thence too much caution cannot be observed either in recommending confinement, or granting a certificate of lunacy, when friends solicit it. This caution is more particularly requisite, as the leaning of lawyers is always in favour of the lunatic; and a man may be somewhat idiotic, a little childish, or even to a certain extent mad, without the law considering him non compos. We ought, also, always to bear in mind, that in ordering the confinement of the insane, we are placing a fellow man at the mercy of those who are to have the charge of him; and if that power be abused, how difficult to substantiate a charge of misconduct or cruelty.

No person can be confined in a lunatic asylum, unless an order is produced from some relative or connexion, duly specified, and a certificate of insanity, either from a Chancery Commission, or a medical one, signed by two physicians, surgeons, or apothecaries, who shall have *separately* examined the patient at two separate times. In pauper cases, one medical certificate is sufficient, but it must be attested by the clergyman and overseers, or by two justices of the peace. Within three days, also, after the patient's admission, notice must be sent to the Clerk of the Commissioners of Lunacy, and his admission registered.

Having taken these views of mental alienation, let us now examine, briefly, the manner in which the medical practitioner should perform his forensic duties in such cases. Let us suppose a case *de lunatico inquirendo*. In order to obtain such an inquiry, the person must be supposed to be either an idiot or a luna-

tic; and these inquiries are ordered upon petitions by private individuals, accompanied by affidavits shewing incapability of managing his affairs by reason of insanity. If the insanity be so obvious that it is readily recognized by the judge and the jury, the physician has an easy task to perform; but where doubt exists, and difficulties arise in determining, then all his skill and experience must be called forward to guide the decision of the Court. He has given the medical certificate of the patient's lunacy, and he is supposed competent to prove the correctness of this—the commission, also, being commonly granted on the affidavit of the medical attendant of the patient. Unsoundness of mind may be alleged against a person by common fame; insanity may be even justly imputed to him by his relations and friends; yet the burthen of the proof is cast upon the medical man, and confinement cannot take place without his authority. If the propriety of the measure be disputed, as has often happened, and the case become one of legal inquiry, the medical witness is called upon not only to state as to the prevailing opinions of the lunatic and his disposition to act upon them, but also, in plain and intelligible language, to give the Court some idea of the general features of the disease. He is also required to state the peculiar propensities of the lunatic; whether they originate purely from the state of insanity: and in the examination of the lunatic by the Commissioners and the Jury, it is his duty to lead the examination into such a channel as will conduct to the full development of the aberration of intellect. This is not, however, to be effected by directly selecting the subjects of the maniac's delusions, as he will often endeavour to evade or pretend to disown them; but his consecutive actions and associations of ideas must be traced down from the origin of his distemper, and in passing over the path in which he originally stumbled, he will again most infallibly trip. It is, however, a very difficult matter to prove insanity; it is not sufficient, especially when the case involves the disposition of property, to prove that the testator was insane. The nature of the disease, the period of its continuance, and the particular acts which characterize it, are all required to be satisfactorily proved. The chief value of such inquiries is to ascertain how far the insanity of the person who is the subject of a Commission renders him incapable of properly managing his property, and mingling in society without annoying others. But it is not enough that such a person has transacted his affairs with some degree of prudence, and forbore, as it were, to follow the impulse of his insane opinions; for this has been the case, and yet suicide has soon followed, or a furious paroxysm of mania displayed itself.

If a medical man is attentive and observing, he can always detect the earlier ap-

proaches of the disease, and it is his duty to demonstrate from the nature and tendency of the attack, that the patient will soon be unfit to be trusted either with the management of his affairs, or to conduct himself properly as a member of society.

In the legal inquiries into insanity, lawyers put a peculiar stress on the term *unsound mind*, which means that a person has not sufficient capacity to conduct his own affairs; thence we hear of decisions in which a person is declared not to be an idiot *ex nativitate*, nor a lunatic, but to be of unsound mind; that is, in a state of mental weakness or imbecility, distinct from either.

But the late Lord Eldon ruled that this was not enough to place a person or his property under a committee of management. "There is," says the learned Chancellor, "a great difference between inability to manage a man's affairs, and imbecility of mind taken as evidence of unsoundness of mind." The case of a man named Charlton Palmer, was one in which, from the person being much stricken in years, he displayed the mind of a child; "it was therefore," says Lord Eldon, "in that sense, imbecility and inability to manage his affairs, which constituted unsoundness of mind." Now let us inquire what degree of imbecility of mind amounts to unsoundness; for it cannot, strictly speaking, be admitted that, because a man's mind is as weak as that of a child, it is necessarily unsound. Unsound mind can only imply insanity; indeed in tracing the derivation of the word, as Dr. Haslam remarks, it seems to be equivalent to the Latin, *Insanus*, from which the Anglo-Saxon unsound is evidently derived. Imbecility implies a degree of mental incapacity equivalent to idiotcy, a degree which renders the person inadequate to the management of his affairs; and which can always be as readily, and even more readily, ascertained than insanity; and includes all the mental evidences which include unsoundness.

If these remarks respecting mental alienation generally, and unsoundness of mind, be correct, there can be no difficulty in knowing the data upon which the physician is authorised to grant a certificate to confine a lunatic, or grant affidavits to obtain a commission *de lunatico inquirendo*. In expressing this opinion, I cannot avoid again impressing upon your minds the great danger of hazarding a hasty opinion, or overstepping in the smallest degree those boundaries and fences which the legislature has properly drawn around the wretched victims of insanity. Although lunatic asylums are no longer to be regarded as prisons for the safe custody and punishment of their unhappy inmates, and now most truly merit the name, as they possess the character of hospitals for the treatment and cure of the most dreadful malady under which humanity can suffer, yet, it is proper that in assigning patients to them, everything

should be done to prevent even the semblance of oppression or injustice.

With respect to the law of lunacy, it is requisite to make a few remarks.

The law throws its shield over persons who are non compos, both because society shall *non compos* them, and individuals shall not defraud them. The justice and expediency of such a power is undeniable: and therefore, when property is at stake, a Commission for inquiry may be obtained upon petition preferred to the Lord Chancellor for that purpose: and whether this is preferred by relations or others, or by information of the Attorney-general, it must be accompanied by affidavits, setting forth the unsound state of mind of the person against whom the commission is desired, and giving instances in proof of the alleged insanity. The necessity of medical assistance in such cases is obvious; and as they necessarily become witnesses, their expenses must be paid. A physician is allowed a guinea, or more if he come from a distance: but this is only conduct money, to bear his expenses to the place of meeting; any further remuneration rests with the parties. Under all circumstances, however, the medical as well as all other witnesses are bound to attend; and if they refuse, the Lord Chancellor will make an order upon them for that purpose.

When artifices are employed to obtain the execution of a will from persons *non compos*, medical persons may be directed to have access to them, even when no inquisition has found them *non compos*; but this will not be granted unless strong reasons are produced for such an indulgence.

I have already stated that insane persons are not chargeable with criminal offences; but their state of mind must be proved by medical men; and in doing this, it is not enough to demonstrate the insanity; the particular kind of it which is pled in excuse must be described and correctly understood. But a *non compos* is not only excused in the commission of criminal offences: every protection is cast around him, lest he should receive injuries from the hands of others, and especially those of a nature to which his mental imbecility peculiarly exposes him. In illustration of this remark, I have selected the following illustration, to shew the danger of professional men forgetting the duty they owe, both to their patient and their profession. (See Col- linson, vol. 1, p. 509).

With respect to lunatic asylums, the regulation of these, and the granting certificates to confine patients within them, the New Lunacy Bill, passed in 1832, has greatly altered the law. I will point out a few of the enactments, particularly referring to medical men, as your present occupations may deny you the time necessary for the attentive perusal of the entire Bill.

In the first place, it defines medical men. (See Bill, p. 962).

In the second place, it points out the necessity for a medical certificate, in order to remove an insane person into a licensed asylum, justly guarding the insane, at the same time, by preventing these certificates from being signed by physicians or medical men, who are proprietors, or any way interested in the success of the asylum. (See Bill, p. 972). Another provision regards the mode in which lunatic paupers

are to be received, (Ib). It enacts that lunatic asylums are to be visited by medical men, (p. 975); in what manner insane persons are to be received into unlicensed houses, (p. 978); and gives forms of the medical certificates required on these occasions, (pp. 987, 988.) In these respects, the law is most explicit; and therefore any infringement cannot be otherwise interpreted than as being culpable, and consequently punishable.

LECTURES

ON THE

INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE XVI.

Conclusion from the preceding Evidences regarding the Vital Principle—Irritability or Vitality a Property of Organized Matter—Solids and Fluids.

SINCE, then, the attempts to establish the existence of a vital principle as an entity may be regarded as having failed—not to mention its incompetency to effect the phenomena which have been attributed to it, even though its existence had been established—we seem compelled to acquiesce in the proposed alternative, and to admit that life is merely an abstract term, used to denote the sum of these phenomena, the forces immediately effecting which are to be sought for, at least partially, in the results of organism (a). It seems, in-

(a) Some faint glimmerings of the true nature of life, had from time to time broken in upon physiologists, even during the long period that the vital principle doctrines remained formally unquestioned; and it was as illumined by one of these, that Mead compared the living body to a machine, endowed with the property of perpetual motion, "owing to its parts being so disposed that, while they performed their respective functions, they constantly and mutually repaired each other." But it was at the hands of John Brown—low as was his condition, vagabond as were his habits, erroneous as were, in many respects, his views, pernicious as was his practice, and scorned and reviled as is for the most part his memory—that the "vital spark of heavenly flame," of which we have been speaking, received its first severe blow, and a degree of closeness and precision was introduced into physiological and pathological reasonings, of which, so long as men had the free use of this *Deus in fabula*, they would of course be destitute. It was he who distinctly shewed, for the first time, about the year 1780, that life as a $\psi\upsilon\chi\eta$, or anima, did not exist, being neither matter itself, as the Stoics and Epicureans among the ancients, and Dr. Priestley among the moderns, had supposed, nor an immaterial substance added to matter, as almost all the rest of the ancients, and so many of the moderns, had imagined; but that, as a *Zoē*, or vita, it consisted merely in a series of phenomena

displayed by organized beings, and resulting from the action of certain exciting powers attached to matter, or a certain susceptibility in other matter of being excited. "In all states of life," says Brown, "man and other animals differ from themselves in their dead state, or from any other inanimate matter, in this faculty alone, that they can be affected by external agents, as well as by certain functions peculiar to themselves, in such a manner that the phenomena peculiar to the living state can be produced;" (*Elements of Medicine*, 1788, vol. i, ch. 2); and this simple and satisfactory view of the matter in general—subject, it is true, to not a few drawbacks on the score of errors in detail, which were inseparable, perhaps, from the infancy of a schism like this, and to many of which allusion will be made in future—was eagerly taken up, and soon became prevalent among physiologists. Among the first to adopt this view was the venerable Blumenbach of Göttingen; who, although he has always continued, like many others, to use the word vital principle, still constantly speaks of it, not as a substance, but as a property—so that the term becomes synonymous with irritability or vitality—and explicitly asserts that no such actions as constitute life can take place except when this property is acted upon by the requisite stimuli. (*Institut. Physiol.* 1786, sect. 4). Similar doctrines were promulgated soon afterwards by Soemmering and

deed, easy to conceive that certain forms of matter may be possessed of properties distinct from such as are either strictly chemical or strictly mechanical—at least, as these properties manifest themselves in inorganic matters—and that, as combustibility and elasticity, as before observed, are properties of certain forms of such matters, so a peculiar susceptibility of another description may be, in like manner, a property of organized tissues; and it seems equally easy to conceive that, as the combustibility of a combustible substance, or the elasticity of one that is elastic, displays itself only when the former is subjected under favourable circumstances to the action of oxygen, or some similar matter when it gives rise to the phenomena of combustion, or the latter is struck by a hard body, when it gives rise to those of sensible motion, so this peculiar susceptibility of organized tissues manifests itself only when such are exposed to the agency of some peculiar powers, when it gives rise to the phenomena of life. It is not life then, but only a necessary condition of life, namely, irritability or vitality, which is the result of organism; and when we speak of organized matter, we mean, not that it is endowed with life—any more than any inorganic matter is endowed with combustion or sensible motion—but only that it possesses a property, which, when acted on by appropriate powers, is competent to give rise to that series of actions in which life consists. Nor is the existence of this property of organized matter at all more doubtful, or its nature at all more obscure, as elsewhere observed, than those

Reil, the latter of whom describes vitality as the effect of the form and constitution of matter, and life as this property in action; (*Archiv. für die Physiologie*, 1796); and they began, about the same time, to be taught in France by Baron Cuvier and Bichât. According to Cuvier—a name still deservedly in the highest repute, not less in physiology, notwithstanding the vituperation of his logic by Dr. Barclay, than in anatomy, notwithstanding the charge of hebetude latterly preferred against him by Geoffroy St. Hilaire—life consists in “l'ensemble des phénomènes qui ont donné lieu à sa formation;” and he well remarks, that to define it with precision is to run over in detail all the characteristic actions of living beings; (*Leçons d'Anat. Comp.* 1799); while Bichât again describes it, in exactly the same acceptance, as “l'ensemble des fonctions,” unfortunately adding, however, “qui résistent à la mort”—unfortunately, because these words, if they are intended to imply that death is anything substantial, are absurd, if only that it is the cessation of life, superfluous—(*Sur la Vie et la Mort.* 1802). The same view of the matter was subsequently taken by Cabanis; according to whom, “Vivre n'est autre chose que recevoir des impressions, et exécuter les mouvements que ces impressions sollicitent;” (*Rapports du Physique et du Moral de l'Homme*, 1805, tom. ii. p. 137); and although he also speaks of a vivifying principle or faculty, namely, irritability or vitality, as “la condition sans laquelle les phénomènes propres aux différens corps organisés ne sauroient avoir lieu,” distinctly adds “Je suis surtout bien loin de vouloir conclure affirmativement de ces phénomènes l'existence d'un Être particulier, remplissant la fonction de principe, et communiquant aux corps les propriétés dont leur fonctions résultent.” (tom. i. p. 245). In the mean time, the same tenets were further maintained in Germany, among many others, by Prochaska and Hildebrandt; and shortly

afterwards were adopted by Mr. Lawrence, who was the first to present them in their properly physiological aspect—for by Brown the application of these doctrines had been principally pathological and therapeutical—to the physiologists of this country. Lawrence speaks of the substantial vital principle, as hastening fast, at the time at which he wrote to “the vault of all the Capulets;” and, following very closely Blumenbach, Cuvier, and Bichât, represents life as “consisting in the assemblage of all the functions or purposes of organized bodies, and the general result of their exercise,” (*Int. to Comp. Anat.* 1816, p. 120), a definition which gave rise to the facetious comparison already spoken of, by Mason Good, of the human frame to a barrel organ. These doctrines of Mr. Lawrence, owing to some foreign leaven with which they were unhappily and very unnecessarily mixed, but which need not be particularly noticed in this place, were for some time any thing but popular in Great Britain; but they were nevertheless adopted, with some mitigations, by Burns, Gordon, Allen, and others, and, not only unmitigated, but in rather an aggravated form, by Sir Charles Morgan. Like his predecessors in the same fields, he defines life to consist in “the sum total of functions which any individual can perform;” but, unlike them, he denies the existence in organized beings, not only of any substantial principle of action, but even of irritability or vitality, as a property essentially distinct from those of which inorganic matters are possessed; “the difference between the two,” he says, “being purely formal.” (*Philosophy of Life*, 1818, p. 29). To this *ultra* proposition, however, as applied to the actions, any more than as applied to the structure of the two, in which respect also, as we have already seen, some attempts have been made to identify them, it is impossible to assent. Similar general doctrines were in the mean time advocated in France, by Magendie,

of such as are strictly chemical or mechanical. The latter, indeed, now frequently engage our attention, and what is familiar we easily persuade ourselves is real and intelligible; the former is seldom the object of our contemplation, and what is rare generally appears at first sight fanciful and abstruse. But upon reflection, we shall find that we have no more evidence of the existence, and know no more of the nature of combustibility, or, of elasticity, than of irritability or vitality. It is from the effects alone of any one of these properties that we infer their existence, and determine their nature; and when we say of one substance that it possesses combustibility, all that we mean is, that when exposed to the action of certain other substances it takes fire; of another, that it possesses elasticity, we mean only that, when struck, it rebounds; and of a third, that it possesses irritability, we mean only that when acted on by certain powers, it manifests life. We know fully as much therefore of any one of these properties as of the rest—that is to say, as we know matter only by its properties, so we know properties only by their effects. We know nothing of any one of these properties in the abstract, nor is it therefore by way of an explanation of any of the phenomena in question, that the terms denoting their properties are used (*a*): they are employed merely as expressive of our belief in the exist-

Broussais, Adelon, Dutrochet, Brâchet, and others—in particular by Adelon, who, after enumerating the chief actions of organized beings, says expressly, “ces actions—constituent une vie;” (*Physiologie de l’Homme*, 1823); and whose three admirable Chapters on the Philosophy of Physiology might serve to settle, in all but the most blindly prejudiced minds, once and for ever the question respecting the existence of life, “comme un Etre réel.” (tom. iv. p. 645). Dr. Milligan, the translator of Magendie, observed, in allusion to the doctrine of a vital principle, “the student will do well, in all such dubious expressions by authors, to substitute for vital principle, the words vital state or vital action.” “The primary idea of life,” he remarks, “in our language, signifies motion—and if we analyze the idea, as it arises in our minds, we shall find that an interest or independent power of motion, accompanied by frequent, actual, appreciable motion, constitutes the whole of our notion of life, before it is adulterated by the study of the natural sciences, and the writings of philosophers.” (Translation of Magendie’s *Comp. of Physiol.* 1823, note to p. 9, l. 16). Mr. Mayo again says, almost in the words of Lawrence, “the term life is a collective expression for an assemblage of phenomena.” (*Outlines of Physiology*, 1827, p. 8). But the author who, in modern times, has most systematically and successfully taken up the cudgels against the substantialists, is Dr. Prichard, who after enumerating, in a most masterly manner, the chief phenomena to explain which a substantial vital principle has been so unnecessarily put in requisition, and showing the polypragmatical and often inconsistent nature of the part assigned to it, concludes “that the hypothesis of a vital principle has been proved, by a careful examination, to be wanting in every characteristic of a legitimate theory.” (*On the Vital Principle*, 1829, p. 132). Dr. Prichard is somewhat too fond of chemical and mechanical explanations of vital processes, but, in as far as he admits of vitality at all, seems to be persuaded that it results from organism;

and it is only from having fallen into the common inaccuracy of confounding vitality with life, that he objects to the definition of life given by Cuvier, Bichât and the rest; he says “that life (meaning vitality) may subsist without the performance of any function.” (p. 1). They agree in fact, but differ in words. Since this time, various other authors have adopted this view of the nature of life—among the rest the laborious and talented Tiedemann, by whom the term life is distinctly restricted to signify the sum of the actions, or, as he calls them, manifestations of activity of organized beings; and who, speaking elsewhere of irritability, or vitality, aptly remarks, “how wrong the physicians and philosophers have been who created it as a fundamental force of life, or the principle of life ($\psi\upsilon\chi\eta$). They have mistaken for the cause of life a simple property of organized bodies, which is the consequence of the plastic force”—(i. e. of their organism). (Translation of Tiedemann’s *Physiology*, by Gully and Lane, 1834, ss. 82 and 557). Lastly, one of the most deservedly celebrated of British physiologists, albeit in some points perhaps mistaken, in a work published only a few months ago, aptly remarks, “Life, without much violence done to language, has been called a forced state. It consists of excitement called into action by suitable stimulants.” (*On Sleep and Death*, 1835). The tendency in the human mind to personify its abstractions, must really be insuperable if it can resist all the weight of reason and authority which may be brought forward against the indulgence of it in this instance.

(*a*) Under whatever terms we may clothe the distinctive property of organized matter, it can signify only, as Magendie remarks, “la cause inconnue des phénomènes de la Vie.” It is not then to anything that we understand better than these phenomena, but to something which we do not understand at all, that we refer when we attribute them to irritability or vitality; and it cannot therefore be by way of *explanation* that we employ these terms. They are the x , says Adelon, of an algebraical problem.

ence of certain forces, which, as recognised by their effects alone, we determine to be distinct, only because these effects are in different cases altogether dissimilar.

The notion of life then to be deduced from what has preceded, is that it consists in the sum of the characteristic actions of organized beings, performed in virtue of a specific susceptibility, acted on by specific stimuli; and as this susceptibility and these stimuli, when natural, may be regarded respectively as the predisposing and exciting causes, as it were, and the actions resulting from them as the proximate cause of *Health*, so it is of some change in the first that every predisposing cause, of some change in the second that every exciting cause, and of some change—or result of such change—in the last, that every proximate cause of *Disease* severally consist. But on this clear and simple doctrine of the connexion between physiology and pathology—in this view of the nature of life—it will be necessary to insist in future: at present we have to inquire a little more particularly into the character and sources of this susceptibility on the one hand, and into the nature of those stimuli by which it is called into action on the other.

These characteristic actions of organized beings have been above shown to be all referable to certain movements effected in either particles or masses of matter. Of the former we have examples in those by which the vessels conveying the mature fluid from the respiratory organ absorb certain gaseous substances from the atmosphere, as well as in those by which the vessels carrying the crude fluids to this organ secrete other gaseous matters to be diffused through it, as in respiration; and again in those by which the vessels proceeding from the heart, or corresponding organ, with the mature fluid, deposit new solids and fluids in every part of the body, as well as in those by which the vessels returning to this organ with the crude fluids break down and carry away old ones, as in nutrition, secretion, and absorption, in the general acceptation of these terms. Of the latter we have examples in those by which the chest and lungs, or corresponding organs, heave and fall upon these gaseous matters, as in respiration; those by which the heart, or corresponding organ, is contracted and dilated upon its blood, as ministering to the circulation of this fluid; those by which the stomach and intestines, or corresponding organs, are elongated and shortened upon the alimentary matters, as in digestion; those by which the gravid uterus, or corresponding organ, expels its contents, as in generation; and those, lastly, by which all the muscles called voluntary act upon the parts to which they are affixed, as in voluntary motion. Now, the first question that arises is, whether does the susceptibility of those movements in which life consists reside in the solids, in the fluids, or in both? Whether it is the mature fluid which *per se* absorbs certain gases, and secretes various solids and fluids; and whether it is the crude fluids which *per se* secrete certain gases, and absorb various solids and fluids, or is it owing to the action of the several vessels which contain these fluids that such movements take place; and again, whether is it spontaneously that the gases enter and depart from the respiratory organ, that the blood issues from and returns to the heart, that the alimentary matters travel along the stomach and intestines, and that the contents of the gravid uterus escape, or is it in virtue of the actions of these several organs that such movements are effected (a)? There is one movement among those above specified,

(a) After what has been already said of the nature of life, it would be absurd to inquire whether it be capable of residing as well in fluids as in solids, since it is obvious that it cannot, as a non-entity, reside in either; and the only question that can by any possibility be mooted—namely, whether fluids and solids may be equally possessed of the property of irritability or vitality—has been already, in a great measure, answered by the two propositions, that this property is the result of organism, and that an organized being is necessarily composed of both solid and fluid parts, and not of either exclusively. It is true that some kinds of microscopic animalcules, as the wheel-animal (*Rotifer*, 1), may be so far dried as to fly in pieces, when touched with the point of a needle, like a piece of salt, without losing their irritability, while other animals, on the contrary, as the sea-blubber (*Medusa*, 4), are naturally of the consistence of a thin jelly, and still abundantly irritable; but neither are the former quite destitute of their nourishing juices, nor the

latter of their solid membranes and vessels. It is probable then that irritability cannot be possessed by exclusively solid or exclusively fluid substances, whether as entire organized beings—could such exist—or as constituent parts of such beings. But, while the several fluid parts of an organized being are strictly what they are represented to be, whatever solid matters they may occasionally hold in solution, the reputedly solid parts of such a being are never without a large admixture of still fluid matters, which continually traverse them: consequently these reputedly solid parts—in other words, the several organized tissues, may be *à priori* inferred to be alone capable of possessing irritability or vitality. It is contended by Blumenbach (*Comment. de Vit. Sang.* 1786), as well as by his commentator, Dr. Elliotson, that there is nothing irrational in assigning life to the fluids as well as to the solids: the latter observing, in support of his position, “it is impossible to deny that the male and female genital fluids are alive—that is, possessed of irritability—because, from their union, a

namely, that of the voluntary muscles, in which the fluids seem to have nothing to do, the action in this case beginning and ending, to all appearance at least, with the solids (a); and in the cases of the ingress and egress of the gases to and from the respiratory organ, the course of the alimentary matters along the digestive canal, and the passage of the contents of the gravid uterus out of this cavity, there cannot be a reasonable doubt that the sole active instruments are the respective solid organs in question. The only movements then, among those above enumerated, in which any active instrumentality can be with the least show of reason attributed to the fluids, are those by which the blood is circulated, and those by which nutrition and secretion, on the one hand, and absorption on the other, are effected—in other words, the only fluids of the animal body—and of those of plants it seems superfluous to speak at present—which can be with any degree of versimilitude presumed to be possessed of the specific susceptibility of action which characterizes living matter, are arterial blood, venous blood, lymph, and chyle (b).

living being is produced.”—(Translation of Instit. of Physiology, 1820, p. 45). But, to say nothing of the male genital fluids, the office of which in generation, since the explosion of the animalcular hypothesis, has not been very well established—although it certainly cannot be conceived to impart much substance to the embryo, if, as Spallanzani calculates, a quantity not exceeding the 2,994,687, 500th part of a grain be sufficient for impregnation—the alleged female genital fluid is not merely a fluid, but, like organized lymph in the case of new growths, a substance possessing from the first such solid as well as fluid parts as are necessary to the manifestation of the plastic power by which all the parts of the embryo are to become developed. If this, then, be all that can be said *à priori* in favour of the presumption of the vitality of the fluids—a presumption which, as remarked by Dr. Milligan, “seems revolting to our common sense”—(Translation of Magendie’s Physiology, 1823, Note to p. 11)—it must be allowed that we have no sufficient grounds *in limine* for questioning the justice of the prevalent opinion upon the subject.

(a) It is proper to observe, that by some physiologists the contractions of muscles in general have been ascribed to the ingress into them of jets of blood or other fluids; but if this doctrine be admitted at all, it must be applied not only to the voluntary muscles, but—perhaps to the muscular coat of the parenchymatous tissue—and certainly to the respiratory muscles, the heart, the muscular coat of the stomach and intestines, the uterus, and in short, all the solid organs, the movements of which are now under consideration, and the whole question of any primary action in the solids becomes at once merged. It will in future, however, be shown that the above hypothesis of the immediate cause of the contractions of muscles is altogether untenable.

(b) That the blood of an animal—to take this as *instar omnium*—contained within itself the substantial life thereof, was distinctly inculcated by Moses (Leviticus, chap. xvii. ver. 7), however sceptical Spencer and others may have expressed themselves on this point; and appears to have been equally clearly implied by Solomon, where he says,

“Out of the heart are the issues of life.” (Prov. chap. iv. ver. 23). The ancient Greek philosophers also continually spoke of the fluids of the body, to the exclusion of the solids, as the immediate domicile of life: and frequently called the blood, τὸ πῶτον τὸν ἀνθρώπου, as something essential directly to accommodate the Πυρ καθαρῶν, or substantial life, under whichever of the thousand and one names this was at different times signified. The same doctrine was reiterated by the poets, both Greek and Roman, who frequently identified the blood with the life or spirit, as in the passage of Virgil,

“Purpuream vomit ille animam.”

(Æneid. lib. ix, l. 349).

And numerous similar passages might be quoted. In modern times this notion was perpetuated principally by Harvey, the reputed discoverer of the circulation of the blood; who represented this blood, not only as “sufficiens et idoneus qui sit immediatum animæ instrumentum,” but also as containing within itself this anima, “non vegetativa modo, sed etiam sensitiva et activa.” (De Generatione Animalium, 1651). It is true the ancient Medean operation of the transfusion of blood, which was introduced soon afterwards by Lower in this country, by Denys and Emerez in France, and by G. Riva and P. Manfredi in Italy, was very far from effecting the metempsychoses which, upon the presumption that the blood of an animal was the life thereof, were fondly anticipated from it, but the doctrine was nevertheless espoused by Glisson and most other authors, down to the time of Haller and Zimmerman, in whose researches on irritability, the blood was taken so little account of, that it sunk into comparative neglect; and this was still further promoted by the theories of Brown, by whom the blood was regarded in the light of a mere stimulus to the solids. The old notion was, however, revived in all its pristine glory by John Hunter; who, unaccustomed as he was to pay any regard to the literature of the science which he cultivated, blindly imagined that it originated with himself, and who represented the blood as containing within it the proper materia vitæ, or the immediate domicile of life—which by him it will be remem-

Letters on Cholera Morbus, addressed to Lord Melbourne. By Scrutator.

SCRUTATOR falls exceeding foul on Lord Melbourne—his Lordship, at the time of the appearance of the letters in some public print, being Secretary for the Home Department—for believing in the contagion of cholera. Scrutator was perfectly right in what he maintained on the subject at that time; but we doubt whether the contagion of cholera is a matter of interest or worthy of question now-a-days: the disease has vanished, the doctrine has been annihilated, and where is the use of thrice slaying the slain? Scrutator deals largely in denunciations of the “humbug,” the “ignorance,” &c. of the Boards of Health of that day, to all which we agree.

The treatment proposed is mightily old-fashioned, and not the better for being old: envelope the whole body and limbs in warm flannel blankets (are there any other kind of blankets?) heat an iron to 130 F. and pass it over the whole body, then rub those parts (body and limbs, we presume,) with mercurial liniment and strong ammonia, (here's a

mess!): during this operation give a mixture composed of tincture of opium, ditto of cantharides, ditto of hyoscyamus, black drop, carbonate of soda, tincture of rhubarb and camphor mixture (a prescription truly à la Huxham), with all which “one grain to 5 or 10 of calomel, and a few grains of camphor” may be taken. The author says, that no one should be allowed to practise medicine who is not “capable of grasping general principles.” Now, both his notions of the nature of cholera and his treatment, which is a treatment of individual symptoms alone, discover any thing but “a grasping of general principles.” We presume not to doubt his experience of cholera cases, but the practical deductions he has drawn from them do not very clearly appear. Withal the style is bad: the author is evidently unaccustomed to the oral or written description of disease: the symptoms are huddled together in a strange way, and under their head he speaks of fear as greatly predisposing to the disease—a cause among the symptoms! Scrutator must not be offended at our *acting* his *name* and *scrutinizing* his errors!

bered was identified with galvanism or electricity—not indeed collected into masses or cords, as in the nervous system commonly so called, but broken down and diffused—the “*materia vitæ diffusa*,” as opposed to “*coacervata*.” A similar view has been since adopted, under various modifications, by Fontana, Wolff, Rudolphi, G. R. Treviranus, Hiedmann, Thackrah, Grainger, Cooper, and many other physiologists; the majority of whom, however, do not indeed assert that the blood is alive, or even that it is *per se* endowed with vitality, but merely that it receives “a vital influence,” or “a vital impression” from the nerves or blood-vessels, which appears to be merely an evasive way of saying that it is neither possessed of vitality nor destitute of it. It is quite true that the blood, while in its proper vessels, whether in the course of circulation or not, resists coagulation for a somewhat longer period, as proved by Thackrah and Cooper, than under other circumstances; but it is not true that this more tardy coagulation implies that any “vital influence”—if by this is meant the slightest possible degree of vitality—has been imparted to it. There has been in the minds of many persons, since the time of Hunter, a kind of morbid association between the continued fluidity of the blood and its supposed vitality; and indeed Mr. Thackrah expressly says “the vital or nervous influence is the source of the blood's fluidity, and its loss the cause of

coagulation.” (On the Blood, 1834). Strange that, if this be the case, it should remain permanently fluid in most cases of sudden death; but the difficulty at once disappears if we regard both its continued fluidity and its coagulation under all circumstances as purely chemical phenomena. How the latter, regarded in this light, should be somewhat retarded when the blood is surrounded by still irritable parts, it will be time enough to attempt to explain when we can tell why fibrin coagulates at any time, and why so many other causes can at one time retard and at another accelerate this process. Every fair view of the matter seems to show that the blood—essential as it is to all the vital actions—is so only in one of two capacities, either as a material to work upon, as it has been already above represented, when it is no more entitled to be considered as possessed of vitality than the food in the stomach, or as stimulus to excite the working organs—that is to say, the heart and capillary system—as it will be represented in future, when it is no more entitled to be regarded vital than caloric or any of the other numerous stimuli to irritability. “No fact,” says Blumenbach—willing as he is to admit the possibility of fluids being possessed of irritability—“No fact has been adduced in favour of the vitality of the blood, which may not be more easily, simply, and naturally explained upon the contrary supposition.”

A NEW PRACTICAL FORMULARY

OF HOSPITALS, OR A

Collection of Formulæ of the Civil and Military Hospitals of France, Germany, Italy, Great Britain and Ireland, &c., containing the Indication of the Doses in which simple Substances, magistral and officinal Preparations of the Codex are administered, the use of New Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M. D., and P. VAVASSEUR, M.D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M. D. &c. &c.

(Continued from p. 248.)

CHAPTER VIII.

MEDICINES WHICH ACT UPON CERTAIN GLANDS, AND UPON THE ABSORBENT SYSTEM IN GENERAL — ALTERATIVES, &c.

MERCURY.

ALL the mercurial preparations act in nearly the same manner. They exercise a stimulating influence over the economy, which may be carried to such an extent as to cause inflammatory action. They act in a remarkable manner on the organs of secretion, and especially on the salivary glands: they also augment the activity of absorption; when employed for a long time, these preparations cause a series of dangerous symptoms—a kind of scorbutic cachexy.

It is chiefly in the treatment of venereal diseases that mercurial preparations are most commonly used. They are also employed in chronic enlargements of the viscera, when not inflammatory, white swellings, &c. The action of mercury appears to be followed with good effects on the whole body in certain local inflammations, such as puerperal peritonitis, &c., and the English practitioners administer them daily in continued fevers, cholera, the yellow fever, plague, inflammation of the brain and its envelopes, hydrocephalus, &c. Preparations of this metal are also used externally in certain herpetic, scrophulous, and verminous affections.

[Calomel and opium are strongly recommended in inflammation of the peritoneum and pleura. I have ordered it in scruple doses, in puerperal and common peritonitis, combined with camphor and opium or morphia, when all other means had failed. I have also used it successfully in cases to which I was called by Dr. Kenny, of the Strand, Mr. Appleton, of Holborn, and others. Dr. O'Beirne narrates several cases of ulceration of the cartilages of the wrist, knee, ankle, and hip joints, successfully treated with mercury, in a paper read before the Surgical Society of Ireland, March 1834, and published in the *Dublin Medical Journal*, No. xiv. vol. 5, May 1834.—T.]

INTERNALLY. ʒij—iv to be taken every two hours in volvulus. (An uncertain remedy).

Decoction. ℥j to Oij of water. It should boil for two hours, and then be decanted. The dose is ʒss—ij daily, which is medicated with some mercurial particles: as an anthelmintic.

Mercuré Gommeux de Plenck. P. Mercury, ʒj, gum. acaciæ, ʒij, syrup of diacodium (poppy). ʒiv. Every ʒ contains a little more than gr. x of mercury. ʒi—ʒi daily, progressively, as an antisyphilitic.

Pilules Mercurielles Composées. P. Mercury, ʒj, triturated until its globules disappear, with honey, ʒxij; during the trituration, add socotorine aloes, scammony, āā ʒij, mace, canella, āā ʒij. Each pill of four grains contains a little less than a quarter of a grain of mercury. [This preparation differs very materially from the mercurial pill of the British pharmacopœias.—T.] Gr. xij—ʒi.

The Oguent Mercurial. P. Is sometimes administered internally in pills, in doses of gr. ij—iv daily; [but scarcely ever in this kingdom.—T.]

Powder of Mercury with Sugar. (Lagneau).

Rx. Hydrarg. purif. ʒij;
Sacchari, ʒss.

Tere simul donec globuli non amplius conspiciantur. Sumat, gr. x, omni mane ex cyatho infusi coffeæ.

In venereal diseases. Nine grains contain 4½ gr. of mercury.

Mercurial Syrup. (Lagneau).

Rx. Hydrarg. purificati, ʒi;
Gummi acaciæ, ʒi;
Syrupi endiviæ. q. s.

Tere simul donec globuli non amplius conspiciantur. Dosis cochlearia ij vel iv in die.

In venereal affections.

Mercury with Chalk. London.

Rx. Hydrargyri. purif. ʒij;
Cretæ præparatæ, ʒv.

Tere simul donec globuli non amplius conspiciantur, gr. iv—x adhibeantur quotidie vel bis in die.

Eight grains of this powder contain three grains of mercury. [This is a valuable medicine combined with rhubarb, aromatic powder, carbonate of iron, and sugar, in proper doses, in cases of delicate children, affected with scrophula, diseases of the mesenteric glands, atrophy, inflammation of the hip, knee, ankle, wrist, and elbow joints, when the alvine motions are brown or depraved. When the alvine dejections are black, I substitute calomel for the above mercurial preparation. The diet should consist of animal and vegetable jellies, and be as nutritious as possible. See the Translator's remarks on the diseases mentioned, in his work on Obstetricy, and in his edition

of Hooper's Physicians' Vade Mecum, 1833.
—T.]

Mercurial Pill. London.

Rx. Hydrargyri purif. 3 ij;
Conf. rosæ gallicæ, 3 iij;
Glycyrrh. rad. contritæ, 3 i.

Hydrargyrum cum confectione tere, donec globuli non amplius conspiciantur deinde adjectâ glycyrrhizæ radice; omnia simul contunde, donec corpus unum sit: gr. iij—vj sumendæ quotidie. [Mr. Abernethy, Dr. Wilson Philip, and others, most strongly advise small doses of mercurial or blue pill in various diseases. The latter gives many remarkable cases of cure effected by 1-24th doses of this remedy as an alterative. (On Small Doses of Mercury, &c. 1834; Abernethy on the Constitutional Origin and Treatment of Local Diseases. T.)

The *Mercurial Pill of the M. de Santé* does not differ from the preceding, except that the confection of roses and the mercury are in equal portions, and the liquorice omitted.

Pills of Mercury and Rhubarb. H. of England.

Rx. Pilulæ hydrargyri,
Pulveris rhei, ā ā 3 ij;
Aquæ puræ, q. s.

Divide in pilulas xxiv, quarum sumat unam vel duas quotidie vel bis in die.

Each pill weighing 6 grains contains gr. $\frac{1}{2}$ of mercury.

Pills of Mercury and Rhubarb. (Ryan).

Rx. Pil. rhei. comp. Ph. Edinb. 3 j;
— hydrargyr. Ph. Lond. gr. vi—x;
Olei menthæ pip. m v.

Fiat massa, in pilulas xv dividenda, quarum capiat unam bis vel ter in die.

[This is an excellent pill in dyspepsia, leucorrhœa, and delicate health, and if continued regularly for three or four weeks in the above, and in cases of bilious complaints, is of essential service. The dose should be increased or diminished, if the bowels act more than twice a day. Tonics are given at the same time.—T.]

Pilules de Belloste. H. des Ven.

Rx. Hydrargyri, 3 i;
Potassæ super-tart. gr. iv;
Scammonizæ gummi,
Jalapæ rad. cont. ā ā 3 i;
Syrupi simplicis, q. s.

Tere hydrargyrum cum aliis donec globuli non amplius conspiciantur. Divide in pilulas granorum, vj, e quibus capiat iij—vj quotidie.

Each pill contains gr. $4\frac{1}{2}$ of mercury. They are generally administered as purgatives.

Pills of Mercurial Ointment. H. de la Ch.

Rx. Unguenti hydrargyri, 3 ij;
Pulveris glycyrrhizæ, q. s.

Divide in pilulas clxiv quarum sumat unam ad sex in die.

In the treatment of venereal diseases.

Two hundred of these pills generally suffice for the treatment. Each of them contains gr. $\frac{1}{2}$ of mercury.

Mercurial Pills, called No. 3. H. St. L.

Rx. Unguenti hydrargyri fortis, 3 vj;
Saponis medicinali, 3 iv;
Amyli, 3 v.

Fiat massa, in pilulas granorum in distribuenda, e quibus capiat unam vel duas mane nocteque.

Each pill contains $\frac{1}{4}$ of a grain of mercury.

EXTERNALLY.

In *Frictions onguent mercuriel* called *Neapolitan*. P. Quicksilver and purified lard of each equal parts.

In *Frictions*—Grey ointment—Neapolitan ointment 25 parts, adeps 75. P. 3 ss—ij. 3 i—3 i, used in frictions in venereal diseases.

The *onguent mercuriel mitigé* of the H. des Ven. is composed of one part of mercury to eight of lard.

Emplâtre de mercure composé, or de Vigo. P. Employed in chronic enlargement of the glands of the groins, testicles, &c.

[In the last stage of puerperal or common peritonitis, and in all diseases in which we wish to affect the system with mercury, hydrocephalus, hysteritis, &c.; a drachm of the British ung. hydrar. fort. should be rubbed into each axilla every quarter of an hour alternately, until one or two ounces are consumed. Six or eight scruples of calomel combined with camphor, morphia, or opium, in the form hereafter mentioned, may be administered at the same time, unless vomiting exist. I have repeatedly succeeded in mercurializing the system by this method, when every other had failed. T.]

Emplâtre des quatre fondants. P. Any quantity.

Mercurial Injection. H. of Germ.

Rx. Hydrargyri, 3 j;
Gummi acaciæ, 3 ss;
Syrupi papaveris, q. s.

Tere simul donec globuli non amplius conspiciantur, dein adde paulatim.

Aquæ, 3 iij.

Fiat injectio cujus 3 i—3 ij utenda bis vel ter in die.

In gonorrhœa and Leucorrhœa.

[This is not much employed in this country. T.]

Mercurial Cerate. H. des Ven.

Rx. Unguenti hydrargyri, 3 ij;
Cerati simplicis, 3 ss.

Employed principally to dress venereal sores and ulcers.

Mercurial Pomade with Opium. H. de la Mat.

Rx. Unguenti hydrargyri
Cerati cum opio, ā ā p. e.

Misce.

Used in frictions twice or thrice a day on

the abdomen, a drachm at a time. It is employed with advantage in the last stage of puerperal peritonitis.

The *Onguent mercuriel opiace* of the H. des Ven. is composed of two parts of mercurial ointment, and one part of opium.

[This ointment is also combined with the preparations of iodine; as will appear hereafter. T.]

Mercurial Soap. H. de la Mat.

Rx. Unguenti hydrargyri, \mathfrak{z} iiss;
Solutionis sodæ, \mathfrak{z} iij.

Tere simul solutionem sodæ et unguentum.

Employed in frictions, in syphilis, scabies, &c.

Mercurial Digestive Ointment. H. des Ven.

Rx. Unguenti hydrargyri;
——— simplicis, $\mathfrak{a}\mathfrak{a}$ \mathfrak{z} iv.

Fiat unguentum.

Employed to stimulate and disperse chronic venereal swellings.

Mercurial Liniment. H. des Ven.

Rx. Unguent. hydrargy. fort.;
Liquoris animoniz, $\mathfrak{a}\mathfrak{a}$ \mathfrak{z} i;
Olei olivæ, \mathfrak{z} j.

Fiat linimentum.

Used to stimulate chronic swellings of a venereal nature.

[Enlargement of the mesenteric glands, hydrocephalus, &c. T.]

Liniment Hydrarg. Lond. & Dublin.

Rx. Ung. hydrarg.
Adipis præpar, $\mathfrak{a}\mathfrak{a}$ \mathfrak{z} iv;
Camphoræ pulv., \mathfrak{z} j;
Spiritus rectificat. \mathfrak{z} j;
Liquoris ammon. \mathfrak{z} iv.

The camphor is first to be rubbed with the spirit of wine, the ointment, lard, and ammonia added. T.]

DEUTO-CHLORURET—OR BICHLORATE OF MERCURY—CORROSIVE SUBLIMATE.

In doses of some grains, it is a most violent corrosive poison; in small doses it acts like the generality of mercurial preparations. It is frequently employed in venereal diseases, especially those of long standing. Its use requires great attention and care.

Subst. Incomp. Alkalies and their carbonates, the tartrate of antimony, the sulphate of potassa, the soaps, iron, copper, lead, mercury in astringent vegetables, &c.

INTERNALLY. Gr. 1-8th— $\frac{1}{2}$ in pills or dissolved in water.

Liqueur de Van Swieten. P. Sublimate, gr. viij; distilled water, \mathfrak{z} xivss; alcohol, \mathfrak{z} jss. \mathfrak{z} ij— \mathfrak{z} i, progressively, in \mathfrak{z} iv of a mucilaginous vehicle. Each drachm of this liquor contains 1-16th part of a grain of the bichlorate. The solution mercurielle, or liqueur de Van Swieten of the H. des Ven. contains about $\frac{1}{4}$ to a drachm. The dose ought consequently to be diminished.

Antisyphilitic Potion. H. of America.

Rx. Hydrargy. bichlorureti, gr. ij;
Aquæ, destillatæ, \mathfrak{z} iv;
Spiritus cinchonæ,
Syrupi simplicis, $\mathfrak{a}\mathfrak{a}$ \mathfrak{z} i.

Fiat mistura, cujus sumat cochleara duo magna bis, vel ter in die.

A spoonful weighing 5 drachms contains about 1-16th of the bichlorate of mercury.

The *Liquor hydrarg. oxym. Lond.* is of oxymur.—bichloruret of mercury, gr. viij, distilled water, \mathfrak{z} xv, rectified spirit, \mathfrak{z} j. \mathfrak{z} j contains gr. $\frac{1}{2}$ of mercury.

It is employed in obstinate syphilitic and cachectic diseases, with sarsaparilla.

Mixture of Bichloruret of Mercury. (Sir Astley Cooper.)

Rx. Tincturæ cinchon. \mathfrak{z} ij;
Hydrarg. oxymur. gr. j.

Sir Astley strongly recommends this mixture in disease of the mesenteric glands, and to substitute tincture of rhubarb, when the bowels are confined. It is given with a view to improve the secretions. The hydrarg. c. creta and rhubarb, are advised as aperients in such cases. I have ordered quinine in good sherry, and also carbonate of iron, both of which children usually take with avidity when sweetened. T.]

MERCURIAL ÆTHER. (Cheron.)

Rx. Hydrargyri deuto-chlorureti,
gr. xvi;
Ætheris sulphurici, \mathfrak{z} i.

Liqua. sumatur, \mathfrak{D} j— \mathfrak{z} ss. bis in die ex cyatho lactis.

A scruple of this solution contains 1-6th of a grain of the bichlorate.

Syrup of Mercurial Ether. (Cheron.)

Rx. Ætheris hydrargyri, \mathfrak{z} ij;
Syrupi simplicis, \mathfrak{z} viij.

Fiat syrupus, cujus sumat, \mathfrak{z} ss—i; ex cyatho lactis.

An ounce contains $\frac{1}{6}$ th of a grain of the bichlorate.

Pills of Bichlorate of Mercury. H. des Ven.

Rx. Hydrarg. bichlorureti, gr. v;
Amyli, \mathfrak{z} i;
Gum. acaciæ, \mathfrak{z} ss;
Aquæ puræ, q. s.

Fiant pilulæ xxxvi quarum capiat unam ad tres quotidie.

Each pill contains $\frac{1}{6}$ grain of the bichlorate.

Pills of the Bichlorate of Mercury. H. of England.

Rx. Hydrargyri bichlorat, gr. viij;
Hydrochloratis ammoniæ, gr. x;
Aquæ ferventis, \mathfrak{z} ij;
Micæ panis, q. s.

Divide in pilulas xl, quarum sumat unam vel duas in die.

Each pill contains 1-5th of a grain of the bichlorate.

Mercurial Pills, called No. 1. H. St. L.

Rx. Hydrarg. bichlor. \mathfrak{D} i;
Alcoholis, \mathfrak{Z} ij;
Micæ panis, \mathfrak{Z} iij;
Aquæ destillatæ, q. s.

Divide in pilulas clxiv ex quibus capiat unam mane nocteque, et deinde duas.

As *antisymphilitics*. Each pill contains $\frac{1}{2}$ of a grain of the bichlorate.

Mercurial Pills, called No. 2. H. de St. L.

Rx. Hydrarg. bichlor. \mathfrak{D} i;
Pulveris rhei, \mathfrak{Z} ij;
Croc. medicinal. \mathfrak{Z} ss;
Pulv. glycyrrh.
Syrup. flor. aurant. \mathfrak{a} a q. s.

Fiant pilulæ clxiv, dosis ut supra.

Each pill contains $\frac{1}{2}$ of a grain of the sublimate.

Antisyphilitic Pills. Hot. D.

Rx. Hydrargyri bichlor.
Extracti opii, \mathfrak{a} a gr. iv.;
———— cinchonæ, gr. c.;
Pulveris cinchonæ, q. s.

Divide in pilulas xx quarum sumat unam ad tres quotidie.

Each pill contains $\frac{1}{2}$ gr. of the bichlorate and opium.

Antisyphilitic and Antiherpetic Pills. H. de la Pitié.

Rx. Hydrarg. bichlor. gr. iij;
Extracti conii,
———— hyoscyam. \mathfrak{a} a gr. xviii;
———— de chrysanthemi, \mathfrak{Z} ss;
———— dulcamaræ,
Saponis duri, \mathfrak{a} a \mathfrak{Z} i.

Divide in pilulas lxxii é quibus una sumatur mane nocteque.

Every six or eight days one should be added to the dose.

Antiherpetic Pills.

Rx. Hydrarg. bichlorat. gr. ij;
Extracti aconiti, \mathfrak{D} i;
Pulveris aconiti. q. s.

Tere in mortario vitreo et divide in pilulas xxiv, quarum sumat unam mane nocteque.

The dose should be progressively augmented.

Employed in cases of syphilitic herpes, swellings of the lymphatic system, &c.

Each of these pills contains one-twelfth gr. of the bichlorate, and one gr. of the aconitum.

EXTERNALLY.—In frictions.

Pommade de Cyrillo. P. Sublimate 4 parts, adeps 32 parts. \mathfrak{Z} ss— \mathfrak{Z} i in frictions.

Lotions. Gr. vj—viij in a solution of \mathfrak{Z} ij of water.

Baths. Gr. x— \mathfrak{Z} j in Occ of water.

Gargles. Gr. i—ij in \mathfrak{Z} iv of a liquid.

Collyria. Gr. $\frac{1}{2}$ —1 in \mathfrak{Z} i of liquid.

Trochisques Escarrotiques. P. Sublimate 8 parts, starch 16 parts, mucilage of tragacanth, a sufficient quantity. Used for the

enlargement of the orifice of fistulous openings.

Mercurial Gargle. H. de la Ch.

Rx. Hydrarg. bichlor. gr. ij;
Aquæ destillatæ, \mathfrak{Z} iv;
Syrupi mellis, \mathfrak{Z} ss.

Misce.

Used in the treatment of angina accompanied with ulceration of the pharynx.

Antisyphilitic Gargle. H. of Italy.

Rx. Hydrargyri bichlor. gr. i;
Decocti hordei, Oj;
Mell. rosæ gallicæ, \mathfrak{Z} ss.

Fiat gargarisma.

Employed in syphilitic angina.

The Syphilitic Gargle of the H. des Ven. is composed of one gr. of the bichlorate and \mathfrak{Z} vi of the decoction of marsh-mallow.

Mercurial Enema. H. of America.

Rx. Hydrargy. bichlor. gr. vi;
Infusi lini, Oj.

Fiat enema.

Employed with advantage in cases of Ascariides.

The Liniment Antisyphilitic of the H. des Ven. contains only gr. ij of the bichlorate dissolved in \mathfrak{Z} ij of distilled water, to the same quantity of the same vehicle. It is sometimes employed in the treatment of venereal diseases, especially those of the rectum, when the stomach cannot bear the internal administration of the bichlorate. It is, however, an uncertain remedy.

Mercurial Collyrium.

Rx. Hydrarg. bichlor., gr. iv;
Aquæ rosæ, \mathfrak{Z} vi.

Fiat collyrium.

Employed in ulcerations of the palpebræ, and in chronic gonorrhæal ophthalmia.

Eau Ophthalmique Mercurielle. H. of Germ.

Rx. Hydrarg. bichlor. gr. ss;
Aquæ rosæ, \mathfrak{Z} iij.

Solve, et adde,

Mucilaginis, \mathfrak{Z} i;

Aquæ destil. lauro-cerasi, gutt. xxx.

Misce.

Used in venereal ophthalmia.

Collyrium of Conrad. H. St. Ant.

Rx. Hydrarg. bichlor. gr. j;
Gum. tragacanth. \mathfrak{D} i;
Liquoris opii, gutt. xvij;
Aquæ rosæ, \mathfrak{Z} iv.

Fiat collyrium.

Employed in certain chronic ophthalmia, especially those dependent on syphilis.

Mercurial Injection with Opium. H. des Ven.

Rx. Hydrarg. bichlor., gr. vi;
Aquæ destillatæ, Oj;
Liquoris opii, \mathfrak{Z} ss.

Fiat injectio.

In syphilitic ulcerations of the genital organs, especially in women.

Detersive Injection. H. of Italy.

R_x. Hydrarg. bichlor., gr. ij ;
Decocti hordei, Oj ;
Tinct. myrrhæ, 3 i.

Misce.

Employed in cases of caries of the bones, dependant on constitutional syphilis.

Mercurial Lotion, or Eau Rouge. H. St. L.

R_x. Hydrarg. bichlor. 3 j ;
Aquæ destill. Oj ;
Anchusæ, q. s.

Fiat lotio.

Used with success in the treatment of herpes, not inflammatory, and especially that of a syphilitic nature. The diseased parts should be bathed with compresses dipped in this fluid.

Camphorated Mercurial Solution. H. of Germ.

R_x. Hydrarg. bichlor. 3 ss ;
Camphoræ, 3 i ;
Spirit rectif. 3 i.

Misce.

This liquor is used in syphilitic condylomata.

Mercurial Bath. M. de Santé.

R_x. Hydrarg. bichlor., 3 ij—3 i ;
Aquæ, Occ.

This bath is used in treating venereal cases when the internal administration of the bichlorate cannot be depended on. In general thirty baths are sufficient ; the quantity of the bichlorate should be gradually increased from 3 ij—3 i.

The Antisyphilitic Baths of the H. des Ven. contain only from 6 to 12 gr. of the bichlorate previously dissolved in distilled water. They are not often prescribed.

PROTOCHLORIDE OR CHLORURET OF MERCURY—CALOMEL.

In moderate doses, calomel is a purgative ; but in smaller ones it acts in the same manner as other mercurial preparations. This preparation of mercury is the one most commonly used, especially in England.

Substan. incomp. Alkalies, lime-water, the sulphates of potass and antimony, iron, copper, &c.

INTERNALLY. As a purgative, gr. v—xv in pills. As an alterative, gr. i—v daily.

Powder of Calomel. (Swediaur.)

R_x. Hydrarg. submuriatis, gr. vi ;
Amyli, gr. xij ;
Sacchari, 3 ss.

Misce pro dosi.

An aperient.

[It is usually combined with jalap ; the compound powder of jalap or rhubarb in the United Kingdom. T.]

Anthelmintic Powder. (Hôt. D.)

R_x. Hydrarg. submur. gr. ij ;
Pulveris rhei, gr. vi ;
——— jalapæ, gr. xxx.

Fiat pulvis.

VOL. VII.

This powder may also be used as a slight purgative.

[Ginger or cinnamon powder should be combined with it. T.]

[Alterative Powders. (Ryan.)]

R_x. Hydrarg. submur. gr. vi—x ;
Pulveris rhei, 3i—3 ss ;
——— cinnam. comp. 3ss—3j ;
Sacchari purificat. 3 ss ;
Pulveris cretæ, c. cum opio. gr. xv in ch. vi vel viij. Dosis una mane nocteque.

These powders will be found efficacious in the cases of infantile remittent fever, in mesenteric disease, in scrophula, rickets, and all diseases in which the alvine motions are dark and offensive. The dose must be increased or diminished, according to the effect on the bowels. T.]

Calomel Powder with Opium. H. of Germ.

R_x. Hydrarg. submur. gr. vi ;
Opii, gr. ij ;
Sacchari, 3 i.

Divide in chartulas vi, quarum sumat unam, quartâ parte horâ.

As an aperient.

Plummer's Alterative Powder.

R_x. Hydrarg. submur., unam partem ;
Sulph. antim. præcip., duas partes.
Fiat pulvis, gr. vi—x quotidie sumenda.
In scrophulous venereal diseases.

The Poudre de Plummer of the H. St. Ant. contains equal parts of calomel and of the hydro-sulphate of antimony, and a part and a half of sugar. It is used in the same cases as the preceding.

Calomel Pills. H. de la Ch.

R_x. Hydrarg. submur.,
Pulveris althææ, ā ā gr. viij ;
Syrupi simplicis, q. s.

Divide in pilulas iij, ex quibus sumat unam quartâ partē horæ.

As an alterative.

[Two grains of calomel with a sixth or a fourth of a grain of opium are made into a pill, and exhibited every hour, or every second hour, in inflammation of the bowels, peritoneum, pleura, uterus, and in gangrene, with the best effects. Mr. Boyle advised scruple doses of calomel in his work on syphilis ; but Dr. James Johnson is entitled to the merit of having first used such doses in India. (On the Diseases of Tropical Climates). Dr. Cartwright, an American physician, employed scruple doses in syphilis, fever, disease of the liver, acute and chronic, dysentery ; and states that he never saw any bad effects produced by them. He ordered a scruple of calomel and four grains of rhubarb, every night, an aperient draught next morning, if necessary ; and he continued the remedy for twelve or sixteen successive nights. Salivation was not produced, but there was tenderness of the gums, with

mercurial odour. A patient may be cured of syphilis by this plan, without being aware of taking mercury, and without any of its bad effects. (*Medico-Chirurgical Review*, 1826).

Dr. Musgrave has exhibited large quantities of calomel, from five to six hundred grains, in repeated doses, with success, in the fever of the West Indies, combined as hereafter mentioned (*Edinb. Med. and Surg. Journ.* 1827, vol. 28); and the medicine has since been pushed to this extent in malignant puerperal fever, in the majority of instances, with the happiest results. I have known it succeed in two cases considered hopeless, accompanied by coffee-coloured vomiting, cold extremities, &c., mercurial ointment, having been freely rubbed into each axilla at the same time, and the vomiting stayed by the effervescing mixture with opium; but I have known it to fail in similar instances.

Dr. Musgrave divides two scruples of calomel and one of camphor into twelve papers, and has given in successive doses 500 grains of the former in this combination. In his opinion, the camphor facilitates the action of the calomel. I have known fatal hypercartharsis caused by a scruple dose of calomel alone, and therefore combine it as follows, in malignant puerperal fever, peritonitis, &c.

Rx. Hydrarg. submur. \mathfrak{Dj} ;
Camphor. pulv. gr. v;
Morphiæ acetatis, gr. $\frac{1}{2}$.

Fiat pulvis, singulis, secundis, vel tertiis horis sumendus.

In extreme cases we must use extreme remedies. I have known a pound of mercurial ointment used in repeated frictions in malignant or blue cholera, without any effect.

The above combination was taken by a patient of mine, affected with syphilis, for nine successive nights, until the gums became tender, which never happened before, though he took oxymuriate of mercury by the advice of two of the most celebrated surgeons in this metropolis, without producing the same effect; and I may add, that the chemist who compounded my prescription was so terrified at the dose, that he marked the packet of powders "Poison—one ordered to be taken at bed time." He was, however, a false prophet, as my patient got speedily well. T.]

Compound Calomel Pills. H. of England.

Rx. Hydrarg. submur.
Antim. sulph. præcip. $\mathfrak{āā}$ 3i;
Guaiaci gummi, 3ij.

Tere et adde,
Mucilaginis acaciæ, q. s.

Divide in pilulas gr. v, capiat unam vel duas in die.

In constitutional syphilis, cutaneous diseases, &c.

Each pill contains about gr. ij of calomel,

and the same quantity of sulphuret of antimony.

Compound of Soap Pills. H. de la Ch.

Rx. Hydrarg. submur.
Jalapæ resinæ,
Saponis medicinalis, $\mathfrak{āā}$ 3i.

Fiat massa, in pilulas granorum iv distribuenda, quarum capiat duas singula semi hora donec alvus soluta sit.

Each pill contains about gr. $1\frac{1}{2}$ of calomel.

The *Pilules Fondantes* of the same hospital are composed of equal parts of soap and calomel, and do not contain the resin of jalap. Three or four are given daily, as alteratives.

Compound Pills of Calomel and Ipecacuanha. H. of England.

Rx. Hydrarg. submur. gr. v;
Pulv. ipecacuanhæ, gr. x;
Conf. rosæ gallicæ, q. s.

Divide in pilulas x, quarum capiat unam ad tres quotidie.

Pills administered in Dropsy. H. de la Ch.

Rx. Hydrarg. submur. gr. viij;
Pulv. scillæ,
—— rhei, $\mathfrak{āā}$ gr. iv;
Syrupi, q. s.

Fiant pilulæ in die, capiendæ.

[Sir Astley Cooper has found the best effects from a pill composed of one grain of calomel, or two of mercurial pill with three grains of squill, every night, or every other night; and the following mixture during the day:—

Rx. Misturæ camphor. \mathfrak{z} iss;
Ammon. carbon. gr. vij—x;
Spiritus æther. nitros. 3j;
Tincturæ digitalis, mxx.

Sit haustus bis in die sumendus. T.]

As Diuretics.

Pilules Suedoises. Hôt. D.

Rx. Hydrarg. submur. 3iss;
—— sulph. nigri,
Hydrosulph. ammoniæ, $\mathfrak{āā}$ 3i;
Micæ panis, q. s.

Fiat massa in pilulas cxliv distribuenda; é quibus ij—iv quotidie sumendæ.

As antisiphilitica.

Each pill contains gr. $\frac{3}{4}$ of calomel.

Antisiphilitic Pills. H. St. L.

Rx. Hydrarg. submur.
Guaiaci resinæ, $\mathfrak{āā}$ 3ij;
Pulveris althææ, 3iv;
Syrupi cydoniæ, q. s.

Divide in pilulas granorum iv, quarum sumat iv—vj in die.

Each pill contains 1 gr. of calomel.

Antisiphilitic Opiate.

Rx. Hydrarg. submur. 3ij;
Opii purific. xiv;
Confectionis rosæ, 3iv.

About the size of a bean of this opiate should be taken in the morning fasting, and

a cupful of the decoction of guaiacum should be administered immediately after each dose, to prevent salivation. Many practitioners prescribe a purgative every fifth or sixth day whilst this medicine is employed.

Laxative Boluses. H. de la Mat.

Rx. Hydrarg. submur. gr. xij;
Magnesiæ sulphatis, gr. xvi;
Syrupi rhamni, q. s.
Fiant boli iv sumantur in die.

Vermifuge Bolus. H. de la Mat.

Rx. Hydrarg. submur. gr. ij;
Seminis santonia, gr. viij;
Camphoræ, gr. vi;
Syrupi simplicis, q. s.
Fiat bolus.

Purgative Pastiles.

Rx. Hydrarg. submur. gr. vi;
Chocolatæ, ʒi.
Fiat trochisci é quibus capiat unum omni nocte.

Very useful to purge infants.

EXTERNALLY. In frictions on the gums, gr. ʒ—i, as an antisyphilitic.

[A better mode of curing new-born infants of syphilis is to exhibit mercurial pill to the mother, or to the infant, in extremely small doses. The first method usually succeeds, and is the safer. T.]

As a topical application, in a pommade, &c.

A Dry Collyrium. H. St. Ant.

Rx. Hydrarg. submur.
Sacchari, ʒ ʒ gr. xx;
Opii purif. gr. iv.

Misce.

[Cujus parum infletur, ope calami, in oculum affectum, semel vel bis in die. T.]

Employed in chronic ophthalmia.

[This practice was often tried by the late Baron Dupuytren, but is not employed in this country.

Daily experience convinces me that the preparations of nitrate of silver, sulphate, copper, &c., are too freely and indiscriminately employed, and do infinitely more harm than good. Cases treated in this way for two years and a half, have fallen under my care; vision was nearly destroyed; the corneæ were nebulous, the eyelids villous; and these disorganizations yielded to mild astringents, such as rose-water, liquor plumbi. acet. dilut., or sulphate of alum, and liq. opii sedat., or to a lotion of three grains of hydriodate of potass to each ounce of rose-water, with ʒss—i of the liq. opii sedativ. Such cases have been repeatedly seen at the Free Hospital and Western Dispensary, by numerous medical students, and some of them are now under treatment and being relieved. The old practice of blowing burnt alum, &c., into the eye for pearl or opacity obtains with quacks and farriers; but with few well-educated medical practitioners in this country. T.]

Honey of Calomel. (Swediaur.)

Rx. Hydrarg. proto chlorureti, ʒi;
Mellis, ʒi.

Misce.

Employed in venereal ulcerations of the throat and the genital organs.

Resolvent Pommade. H. Dieu.

Rx. Hydrarg. submur.
Pulv. scillæ, ʒ ʒ ʒss;
Adipis, ʒij;
Olei rosæ, gutt. iv.

Fiat unguentum.

Employed in frictions in cases of chronic enlargement of the articulations.

Anti-herpetic Pommade. H. de la Ch.

Rx. Hydrarg. submur.
Sulphuris, ʒi;
Adipis præp. ʒi.
Fiat unguentum.

Pommade used in the Treatment of Tetters.
Hôt. D.

Rx. Hydrarg. submur. ʒij;
Ung. rosæ, ʒij.

The *Pommade Fondante* of la Char. differs from the preceding. It is composed of equal parts of calomel and cerate. It is chiefly employed in frictions on the abdomen in engorgement of the liver.

[The ointment of the hydriodate of potass, of the proto-ioduret of mercury, or other iodureted preparations, which will be hereafter described, are much more efficacious.

The proto-chloride or chloruret of mercury, commonly called calomel, has long been used in venereal and liver complaints, in thoracic and abdominal inflammations, combined with opium, in scrophula, rickets, and enlargement of the mesenteric glands, in combination with rhubarb, opium, or cicuta; in dropsies with squill, foxglove, compound powder of jalap, and elaterium; and in rheumatism and obstinate cutaneous diseases with antimonials, guaiacum, sulphur, and other sudorifics. It may be observed, that children bear much larger doses of calomel than adults. Professor Hamilton, of Edinburgh, exhibited 180 grains to an infant under two years of age in croup, and others have pushed it much farther in hydrocephalus. The late Dr. Darwall, of Birmingham, inveighed in strong terms against the common custom of exhibiting calomel for a long time in cold weather to children; but I have never observed bad effects from it, when administered as an alterative in the coldest weather. It is seldom necessary, according to my experience, to continue it, in the fevers, in combination with rhubarb, jalap, &c., inflammatory or cachectic diseases of infants, longer than two or three weeks; and I have not as yet seen any bad effect produced by it.

It is a medical, as well as a vulgar error, that cold drink is prejudicial during the use of this remedy. Experience has long since

convinced me of the opposite opinion. I have never seen bad effects ensue from the use of cold water, barley water, milk and water, tea, &c., given to infants and children, in infantile remittent fever, or what is popularly termed "fever from teething, worm fevers," &c., during the administration of calomel, or chalk with mercury; and every pathologist will perceive the reason, which I cannot attempt to explain in a work of this kind.

There is an external application of calomel which must not be forgotten. It is the *lotio nigra*, or black wash of surgeons: 3ij of calomel to Oj of lime water. This is applied to chancres, excoriations, and to the prepuce of the glans of the clitoris in female children affected with a purulent discharge (Sir A. Cooper), which is not gonorrhœa (Sir A. Cooper, Professors Hamilton, Burns, Dewees, &c., &c.)

The *lotio flava*, or yellow lotion, is now seldom employed, and is composed of bichloruret, or oxymuriate of mercury (corrosive sublimate), gr. xv, and liquor calcis (lime water), a pint. It was used in venereal and scrophulous ulcers, and cutaneous diseases. T.]

(To be continued).

LETTER ON HOSPITALS AND DISPENSARIES.

Addressed to H. Warburton, Esq., M. P.

March 2nd. 1835.

SIR—From a firm conviction that you are determined to devote much of your attention to the prosperity and happiness of your country, and that all evils will be duly probed, with a view to their extinction, I am induced, without circumlocution, to state, that the receiving rooms of the hospitals, dispensaries, and parochial infirmaries of the metropolis, are daily and hourly receptacles of infectious and contagious diseases of the most inveterate character, such as scarlatina, measles, small-pox, hooping cough, besides many other cutaneous diseases of the most disgusting and infectious character. My great object is to bring under your active and discerning mind the fact of these contagious and infectious diseases being often fatally conveyed from these receiving rooms into the bosoms of noble, wealthy, and highly respectable families, as well as into schools of every description, by the domestics thereof, who frequent such receiving rooms for relief from disease, or by the friends of these domestics with whom such may hold intercourse.

Small-pox, scarlatina, measles, and other contagious maladies often make their appearance in families and schools, and no one acknowledges the source from which

they have originated; but the above short recital will come painfully home to many who have suffered under this direful and destructive system. These receiving rooms as at present conducted, are to be regarded as the centres from which fatal diseases are often disseminated over the metropolis; and while these arrangements inflict misery on the community, they fill the coffers of the profession and particularly those of the hospital departments.

Had the presidents and fellows of the College of Physicians and Surgeons been as faithful guardians of the public as they have been assiduously attentive to their own interests, the hydra, small-pox, would have been long ago strangled, but the *auri sacra fames* prevailed over the duties of humanity, and these evils still continue in full force, and are hidden from the public eye by being erroneously associated with benevolence and charity.

Many lives would be in future saved in every grade of society, as well as serious expense avoided, if it were directed by the legislature that patients labouring under contagious diseases of the nature delineated should not be carried through the streets, or allowed to enter the receiving rooms of hospitals, dispensaries, and parochial infirmaries, but that such cases should be attended at their own abodes. An arrangement of this nature would be worthy of the humane character to whom they are addressed, as it were in vain to expect aid from the College of Physicians, whose rapacity and vanity absorb all other considerations. Under this evil genius, the real utility and advantages of our hospitals and public medical institutions have been nearly annihilated; and hence the great inferiority of this country in anatomy, physiology, pathology, chymistry, and hospitals, when compared with the Continent at large, but particularly France; and these evils are much augmented by the absurd divisions and restraints existing in the profession, originating in pride, avarice, and other follies and vices. A foreign writer of great talent and humanity, regards our hospitals as a species of joint-stock-jobbing corporate bodies, of the rotten borough kind, and conducted as he states, with "Fierté," and from which those actually destitute derive little or no advantage as a letter must be obtained before admission. This system is bad and disgraceful—*Delenda est Carthago*. The money taken from the pockets of young men by the College of Surgeons, in the capacity of examiners, the members of the said College having previously received large sums from these young gentlemen for instruction, is most disgraceful.

What would be thought of the goldsmith or merchant, or tradesman of any description, who not content with being amply paid even beforehand for their goods, should demand an exorbitant price for the

invoice which recorded qualities? These examinations, and diplomas consequent thereon, should be conferred gratuitously by the universities and schools where such gentlemen have studied.

This would remove the strong objection to the Universities examining their own pupils; and these examinations should be open to the profession at large. The intrigues of the Colleges have rendered our Medical Institutions and hospitals comparatively useless, as instead of being rich in genius and talent, and thereby possessing the power of conveying useful information to the medical student, as to the cure of disease, they are to be regarded as a corporate puddle, more likely by their example to defile, than to give a generous impulse to the rising generation.

Such a junta, strangers to virtue, cannot be much longer allowed to insult an enlightened community and liberal profession. The hospitals of the metropolis they have deprived of the character of charitable institutions, as no individual, however severely afflicted with disease, can obtain admission, as the result of these afflictions. Such is not the case in Paris, as any individual presenting himself at one of the hospitals, labouring under disease, receives immediate admission if the case should require it. In former times, no one, however ignorant, who could command the examination fees, was rejected by the College of Surgeons, and these went forth as so many lion's providers for the hospital surgeons, as in all cases of difficulty they were sent for, as the result of the incapacity on the side of the newly made surgeon; and hence fatal and dangerous delay as well as expense were incurred. In conclusion, let me observe that the Colleges of Surgeons and Physicians are a hive of old sinners, whose crimes spring from avarice, which never fails to deaden every elevated and tender sentiment common to our nature. A death-bed repentance is not to be looked for—none of the old leaven must be left to infect the pure institutions that are likely to arise out of the late investigations. Stern necessity, not severity, requires that the Warburton knife should be applied with a free and determined hand, so that their multiplied deformities may be not only subdued, but utterly extirpated.

I have the honour to be, Sir,
Your obedient Servant,
CELSUS.

H. Warburton, Esq., M. P.

—o—

MEDICAL OFFICERS AT NEWCASTLE-
UPON-TYNE.

To the Editor of the Original London Medical
and Surgical Journal.

SIR—In accordance with the postscript to my last letter, I now proceed to the consi-

deration of the present state of our Dispensary. The only circumstance connected with its general management, on which I shall make any comment, is, that patients to be admitted to the benefits of the charity must provide themselves with a letter, "signed by a Subscriber, and addressed to the House-Apothecary." Although this system of recommendation is not limited to the Newcastle Dispensary, it is one which in many respects is objectionable. In the first place, in many serious cases of acute disease, much valuable time is lost; secondly, the persons so recommended very frequently are not objects of charity, but, on the contrary, are capable of remunerating the private practitioner. In the case of acute disease, the opportunity of arresting its progress is utterly lost; and, in the last, a double injury is produced, first, to the institution itself, secondly, to the private practitioner. No one can be more perfectly convinced of the utility of dispensaries than I am; but experience has proved to me, that by this system of recommendation, many real objects of compassion are deprived of their benefits, and many are substituted for them who ought to be considered as inadmissible. The only recommendation, in my opinion, ought to be the combination of poverty and disease. I shall now offer a few remarks on the "Medical Economy of the Establishment." The Dispensary has "six physicians, one surgeon, and a resident surgeon and apothecary;" there being neither consulting physician nor consulting surgeon. This last remark is made in consequence of the physicians being, *strictly speaking*, all consulting officers, as will appear from the following extract from the Dispensary Report:—"In acute diseases, especially in fevers, it will be necessary for the physicians to visit patients frequently; and, in the intervals, the surgeon and apothecary of the institution should also visit them as often as their cases may require." This rule I know to be most scrupulously attended to by at least a majority of the physicians of the institution, and, no doubt, has the advantage of saving them a great deal of trouble; whether it is one which tends to the advantage of the patients, appears to me to be a question of some importance, and, consequently, deserving consideration.

The physicians of the Dispensary alternately receive patients, who, when able to do so, attend on "stated days and hours at the Dispensary only." In cases where patients are able to do this, the present system may answer very well: but not so where the disease is of such a nature as to confine the patient at-home; and here it is that the evil of the rule quoted operates. To be convinced that such evil is not imaginary, I shall suppose a case of serious disease, and, perhaps, not well defined in its character; it is seen by the physician, who turns it over to the surgeon or apothecary, for days, and,

perhaps, does not again see it unless requested to do so, in consequence of some "material change which may require the more immediate attention of the physician." Every professional man must be ready to acknowledge the disadvantage which arises from a plurality of medical attendants in any case, except where met together for the purpose of consultation; and yet we find that this is sanctioned by the rules of the Dispensary, and acted up to by the physicians. In all well-regulated medical institutions, we find that the medical officers are divided into "consulting" and "ordinary." The duty of the former being to consult with the latter, when called upon so to do; and where a further division exists, as "physicians" and "surgeons," it is generally understood that the one class attends to "medical," the other to "surgical cases." But by the rules of the Dispensary all these distinctions are set aside, and the surgeon has to attend to the cases admitted, and which ought to be attended by the physicians. What is the effect of this in our Dispensary? It is simply this—the whole onus of the ordinary duties of the institution devolves upon the surgeon and resident surgeon and apothecary. This is a state of things which ought not to continue; the prosperity of the institution and the welfare of its patients demand a change. And if the physicians, who are at present connected with the Dispensary as ordinary officers, cannot, from their duties as private practitioners, dedicate a sufficient portion of their time to the public duties which they have imposed upon themselves, it is to be remembered by the Governors of the Dispensary, that in Newcastle there are several junior physicians, who are both *able* and *willing* effectually to discharge such duties to the Dispensary. When I write the last part of the preceding sentence, I am aware that the "cuckoo song" may be resorted to, viz.: that it is better to have "men of experience" connected with public institutions. In reply to the vague and frequently misapplied term, experience—I would ask in what experience consists? Is that man experienced who sees a great number of patients daily, and who, perhaps, *has not time to reflect* upon one? Such does not, in my opinion, constitute experience. In this dissent from the common mode of estimating experience, I am borne out by high authorities; but shall content myself with vindicating the claims of young practitioners, by an appeal to one of the highest authorities and brightest ornaments in our profession. The following are the words of the late celebrated Dr. Gregory: "But mere standing or seniority, superadded to the most complete and regular education in the profession, will neither procure confidence from the public, nor success and employment to any person. We are well accustomed to see many juniors surpass and deservedly surpass their seniors—perhaps even

their own instructors—and leave them so far behind, that before half their race is run, they can have no farther hopes of success." Again, "Some individuals soon shew by their talents, and the use which they make of them, that they can profit more by seven years of observation and experience, than others could do in the longest life. And very many soon shew that they are incapable of improving." &c. &c.* It would be well for more than one public institution with which I am acquainted, if the foregoing extract were printed in large characters, and placed in the committee rooms of the governors of such establishments. In conclusion of this communication, I may state, that, so far as I know, the Dispensary has not a single pupil, except the apprentices of the institution. No lectures or other species of instruction are given at the Dispensary; and in this way the advantages to be derived from the experience of two thousand eight hundred and fifty-two cases, have in the last year been lost to the medical students of Newcastle.

I shall continue this subject at an early opportunity, and have the honour to remain,

Sir,

Your obedient Servant,

GEORGE FIFE, M.D.

—o—

MR. DYER ON WATER DRESSINGS.

To the Editor of the Original London Medical and Surgical Journal.

SIR—In making a few remarks upon the paper of Mr. Wilson, contained in your Number of last Saturday, I trust I shall not be accused of doubting the efficacy of water dressing in many cases of ulcer, &c. I should have been glad had Mr. W. been more specific in his account of the particular kinds of sores in which he had seen water dressing successful; for it is admitted on all hands that there is a number of local diseases depending upon constitutional causes, which will not get well by any local treatment. That the Author of good and evil has given us a sufficient remedy for every case, I cannot doubt; but we lack the requisite knowledge to apply it with success, and ever will, unless we attend closely to the minute shades of difference exhibited by disease in different individuals. The following paragraph is a heavy tax upon my credulity. "It was probably the mere physical effects of water that were exercised in the cure of *Nahman* the Syrian, when he was ordered by the prophet *Elias* to 'go and wash seven times in Jordan.'" It would be no difficult thing to account for every manifestation of God's power recorded in the old Testament, on this same plan of "physical effect," and thus at once

* Dr. Ryan's Manual of Medical Jurisprudence, pp. 63-4.

undermine the whole fabric raised to witness the omnipotence of Jehovah.

M. W. evidently believes that the healing of the Syrian Captain took place as described, but that it was caused by the physical (medicinal?) effect of the water, and not by the power of the Lord given to this prophet. Does he also believe that water ordinarily will cure leprosy (*lepra vulgaris*), by dipping in it seven times; or is he aware that Jordan possessed peculiar properties? Does he know one river in the present day that will heal the leprosy. We occasionally see a mild disease compared with that which visited the Syrians, Arabians, and Jews of old. If he knows there is such a water, the discovery will immortalize his name; and if he does not, it appears to me injudicious to wrest a scriptural text from its original intention, in support of a doctrine with which it has no connexion. The object of Elisha in healing Naaman was to make known the might of God, and to give another proof of it to the unbelieving Jews. If it is believed that the leper was cured by the means pointed out, there is no reason left to doubt the fact that Gehazi was punished; and surely He who could cause disease by his word, could also take it away. Had the proud Captain of Syria gone and tried the virtues of his Abana and Pharpar, despising Jordan, he would have found his leprosy still remain, and would have discovered that God works by means, but that he will have the means appointed by himself. The Pool of Bethesda would have had no virtue to those who rushed into it at any season, but they who believed that an angel came down at a certain period and troubled the water—believed, also, that there was one who could give the angel power to render the fluid sanative. It was faith that made him whole who first stepped in—that faith which “can remove mountains.” Doubtless Elisha could by a word have healed Naaman, but he preferred to make trial of his faith, and to see it proved by his using the simple plan he had propounded.

I anticipate much pleasure, and not less profit, from the second contribution of Mr. W. to your valuable pages. I trust he will not be sparing of his cases; they are like water, invaluable, and worth a ship-load of theories.

I am, Sir,

Your's obediently,

JOHN C. W. DYER.

10, Mount Row, Liverpool Road,

March 23rd, 1835.

—o—

The London Medical

AND

Surgical Journal.

Saturday, March 28th, 1835.

ESTABLISHMENT OF A BOARD IN LONDON FOR CONFERRING MEDICAL DEGREES.

It is at length determined that a board shall be constituted in London for conferring medical degrees. The restriction of this power to the London University and King's College, would involve the ruin of other schools of prior institution, and at least equal utility. Mr. Took has therefore abandoned his intended motion in favour of the University, and Mr. Warburton, though a zealous friend to that institution, has declared himself opposed to investing it with any exclusive privilege.

We have good reason for believing that the board about to be formed will be composed of a certain number of members of the Colleges of Physicians and Surgeons, and of lecturers from the several established schools, to be elected by ballot immediately before the commencement of the examinations—which will probably take place some time during the summer. Such an arrangement will secure the competency and fair election of examiners, and emancipate the student from all fear of favouritism, since the teacher and pupil will be mutually ignorant of the relation in which they may in future be placed as examiner and candidate. This is, perhaps, on the whole, the best plan that can be adopted; though the necessity for having recourse to it, and the difficulties attending its adjustment, reflect deeply on the public neglect of learning and science in this metropolis, where the “*amor sceleratus habendi*” seems for centuries to have engrossed the attention, nay absorbed the very souls, of men. All the great continental capitals have long had their universities protected by government, sanction-

ed by time, and adorned with the names of men illustrious in literature and science; while in this proud and great, but in many respects semi-barbarous land, two country boarding schools have been allowed to restrain all academical honour within their own precincts; and though it were unjust to deny that they have fostered some of the finest of human minds, it is equally true that they have greatly retarded the general progress of knowledge and civilisation, by the cultivation of classics and mathematics to the exclusion of other studies quite as important, and by instilling an illiberal and bigoted spirit into the minds of our youth. What is more to the present purpose, they have exerted a paralysing influence on medicine, by their supine indifference to the science—by the inadequacy of their education—and the worthlessness of their degrees.

What has been the result of all these things? That which legislation has omitted to frame, the wants of society have called into being, though in an imperfect form; and if no *Alma Mater* rears her venerable head in the metropolis of the world, the “disjecta membra” of one lie scattered over its vast extent. A *diffused* university, if we may be allowed the expression, has been formed of various insulated schools, which, however, mar each others’ utility by their mutual jealousies and conflicting interests.

It is to be hoped that the construction of such a board as that in contemplation may go far, if not to unite them into one body, at least to animate them with one spirit; and it may, we think, be expected eventually to conduce to what has been laughed to scorn by many, but what will inevitably take place at last—the establishment of *one Medical Faculty*, and the obliteration of those relics of by-gone and benighted times, distinct Colleges of Physicians and Surgeons. It will of course instantly dry up that recent and contemptible

spurt from the fountain of insolence, the Rhabarbarian Fraternity.

We do not know what will be the precise nature of the degrees given by the new board—whether there will be separate degrees in physic and in surgery, or whether the two will be united; but we would strongly recommend that the candidate, after a full and fair examination in every branch of medicine, should be constituted a Doctor of Physic and Surgery. The existing corporations may attempt to prevent the new graduates from *practising* in virtue of their degrees; but in such a case we would advise both them and all other members of the profession, to set the corporations at open defiance. The local privileges by which certain bodies are now enabled to arrest the career of the medical practitioner every time he changes the place of his abode, by obliging him to pass idle and vexatious examinations, and to neglect his practice for the purpose of cramming his brains with school-boy nonsense, which he has long forgotten and will forget again—all this we say is a nuisance so intolerable, that it ought at once to be flung off with a resolute hand. If the members of the profession henceforth act with proper spirit, the power of the corporations will become merely nominal.

A contemporary of ours, remarkable *late ly* for reforming zeal, and *always* for consistency, exults at the bad success of the university “scheme of dealing in medical degrees.” We for our own part are equally rejoiced at the miscarriage of the Pall Mall “scheme,” the result of which would probably have been, that the College, seeing it was all up with the abstract dignity of the fellowship, would have solaced itself with tangibilities, and, converting the Temple of Æsculapius into a diploma shop, similar to that in Lincoln’s Inn Fields, would have dubbed Doctors as fast as the Doctors would pay for being dubbed.

Before quitting this subject, we may be allowed to express a hope that the new arrangements will involve some more liberal regulations respecting the qualification of teachers. Our readers are aware that we regard the whole system of *certificates* as essentially bad, and think that *knowledge*, no matter how or where acquired, ought to be the only thing demanded from the candidate; but if the old system is to be kept up for a while, we trust that the qualification of lecturers will be determined by some juster criterion than at present. With regard to the recognition of surgical lectures, the question has hitherto had no reference whatever to a man's talents or acquirements, but simply to his being one of the *twenty-two*, or one favoured by that august oligarchy; with regard to the recognition of lectures on the practice of physic, the question has been, whether the aspirant was a fellow of the College of Physicians—which ought to have been anything but a recommendation—or a licentiate of the same body; the latter involving a species of degradation to which men indued with the smallest self-respect have always submitted with extreme reluctance.

We cannot easily conceive how an individual who has knowledge sufficient for the *practice* of his profession, can be deficient in the knowledge requisite for *teaching* it; and of his eloquence or amenity as a lecturer, no cognisance has ever yet been taken.

—Cui lecta potenter erit res,
Nec facundia deseret hunc, nec lucidus
ordo.

If, however, any additional proof of qualification be required, let that proof be sought in a fair examination, and not in a local habitation or a name.

Foreign Medicine.

Indigo in Spasmodic Diseases.

INDIGO given in graduated doses, at first a scruple three times a day, and subsequently

half an ounce, in ten cases of epilepsy produced no result whatever, except colouring the urine and motions. In four cases of hysteria the following phenomena were observed; after the administration of two drachms of indigo, a violent renal colic came on; the urine was of a very deep blue colour, and deposited a considerable quantity of very finely powdered indigo. The colic lasted four days, and only yielded to the continued use of oily emulsion. In only one case, after the usual colic had ceased, the nervous symptoms were suspended, nor indeed have they returned at this period (three months after). In two cases remarkable effects on the womb were produced; an amenorrhœa which was concomitant with hysteria was relieved without any cessation of the latter. In two cases of chorea, the indigo had no effect. M. Strahl therefore concludes that this substance is of no benefit in nervous affections, but that it appears to have a decided action on the genito—urinary system.—*Journal des Chirurgie und Augen-Heilkunde*, vol. 22.

Obliteration of the Intestine at the Ileo-cæcal Valve; Sac from the Ileum, containing 92 leaden Shots, and 120 Plum-stones.

Lami, aged 32, entered the Hôtel Dieu on the 12th of January, 1833. He had been ill for a month, and complained of pains in the belly; he had constant nausea and frequent vomiting; by the rectum, he was only able to pass a small quantity of liquid matter, and that after considerable efforts.

The pulse is natural, as is also the respiration; the tongue is healthy, the epigastrium free from pain; there is a dull sound in the centre of the abdomen; the stools are liquid and yellow. These symptoms, added to the emaciation, originated a belief in the existence of an affection of the mesenteric glands and vessels. The patient remained in this condition a fortnight; the vomiting ceased, but the state of the abdomen and of the stools were the same.

He left the hospital on the 2nd of February, and in three days again entered. There was then observed in the right iliac region, and approaching the umbilicus, a middle-sized, unequal tumour, which moved under the hand. This circumstance rather tended to confirm the former diagnosis, and no doubt was now entertained of the existence of a tuberculous affection of the mesenteric glands. (Iodurated ointment was rubbed upon the abdomen, iodine given internally, and emollient clysters administered). On the 10th of February, the tumour was treble the size it had been the night before; was hard but less mobile than before; handling caused pain in it. The difficulty of passing a stool was extreme. The 15th, sensibility over the whole abdomen is very great; the hand applied over the tumour is insupportable; there is vomiting, small and rapid

pulse, contracted features; the patient is in a state of utter fear and anxiety, and raves about shots and death; he might have been considered delirious, but in other respects he gave every evidence of sound intellect. The following morning the peritonitis had acquired a high degree of intensity; the patient had not a moment of quietude. He died in the course of the day.

Dissection 26 hours after death. From 15 to 18 ounces of a reddish fluid are in the peritoneal sac; recently formed false membranes, and all the usual marks of peritoneal inflammation. The small intestine is enormously dilated, whilst the colon and rectum are diminished. At the junction of the ilium with the cecum, a sac as large as the head of a foetus is found thrown towards the umbilicus, and covered with the mass of the small intestines. Adhesions, some old, others recent, keep it fixed to the posterior surface of the abdomen, the mesentery, and some intestinal folds. The parietes of this sac are thick and of a brown colour; on opening it, 120 plum-stones and 92 shots are seen. The stones are black, and as it were macerated in the liquid matters, in which they float; in other respects they are unchanged, and contain each a fresh kernel. The shots, of size No. 2, are also blackened, and were here and there depressed. There are also some cherry stones. The sac in which they are contained is continuous with the ilium, and seemed to be formed at the expense of the latter. The ileo-cæcal valve, which corresponded to the right and lower portion of the sac, was almost entirely obliterated, and only exhibited a very small perforation through which liquid matters alone could pass. The mesenteric glands were perfectly healthy, and none of the other organs had any morbid appearances.—*Gazette Medicale, February 28, 1835.*

[The *Gazette Medicale* very properly remarks that the above case is exceedingly interesting, from the fact of a diagnosis so wide of the mark having been given. The commemorative circumstances are very deficient; but it may be naturally presumed that the primary affection was an obliteration of the intestinal canal, which, as it caused immense difficulty in passing stools, may have given the patient the idea of swallowing, first plum-stones, and subsequently shots, in order to overcome the obstacle of the passage of faecal matters].

Carbonic Acid Fumigations in painful Amenorrhœa.

M. Majon, acting under the theory that carbonic acid, far from being a stimulant, is an antiphlogistic, proposes to employ it in the amenorrhœa accompanied with acute pains of the loins and uterus. The fumigations are applied by means of a gum-elastic tube, the free end of which is introduced into the vagina; carbonic acid is disengaged from

carbonate of lime, by diluted muriatic acid at the other extremity of, and passes along the tube. The fumigation should be repeated twice a day during the time immediately preceding the menstrual period. By it not only the course of the menses is regulated, but the pains also which precede succeed, and accompany them, are prevented.

Fumigations with carbonic acid may also be used in cystitis, ophthalmia and other local inflammations. M. Majon is of opinion that it both acts by diminishing the plasticity of the blood, and by relaxing and narcotising the animal fibre.

The gas may be carried about in caoutchouc bottles, to which tubes of any size may be affixed, and the fumigation made as in the former instance.—*Gazette des Hôpitaux, Feb. 26, 1835.*

Effect of the Employment of Gelatine as Food, in the Development and Maintenance of Muscular Power.

In a former memoir, M. Edwards, in conjunction with M. Balzac, examined the influence of gelatinous aliment on the weight of the body, the experiments to this end having been made on animals that could be treated in any rough manner. But in order to apply the results to many, the species chosen was one whose digestive functions were nearly allied with our own.

In ascertaining the effects of gelatine, it was employed in two different states, first, in a state of purity, and consequently mawkish and insipid, and again, somewhat dressed (*aromatisee*). In the former case it was proved, both by the effects on the weight of the body and by the continued existence of the animals subjected to its use, that gelatine in a state of purity was nutritious in a degree, but is not sufficient of itself to preserve life; as indeed is the case with other alimentary substances, and even bread.

The experiments of the same gentleman also went to shew that a continuation of bread and gelatine was also insufficient for the preservation of life, though the exhaustion of the latter was somewhat more gradual than when either material was employed alone.

As regards dressed gelatine, that is, dressed with the sapid and odorous part of meat, M. M. Edwards' and Balzac's experiments shew that this substance thus modified, possesses highly nutritious qualities, so much so that such an addition afforded all the dietetic qualities essential to the preservation of the weight and even to the growth of the body.

In the experiments made on dogs, they ascertained, to a certain degree, the greater or less activity and strength dependent on the variations of diet; but an exact calculation could not be made. In the experiments on men, the sensation of exhaustion or power could only be approached in

measurement, and it was therefore necessary to have recourse to some mechanical means, to ascertain exactly the variations of strength; but it was more particularly necessary to observe whether, independently of diet, there were not causes tending to produce variations of strength, and should such be discovered, to learn whether these variations could be subjected to some regular law.

By means of a dynamometer, M. Edwards measured the strength of one individual at five different periods of the day; at 7 o'clock in the morning; 11 in the morning; one o'clock; 7 in the evening and 11 in the evening. These experiments, repeated during 10 successive days, and in similar circumstances, gave the following average figures of the strength of the hand:

7 in the morning	67,7
11	72,1
1	73
7 in the evening	71,2
11	67,6.

Thus, from the time of rising at seven in the morning up to one o'clock, the strength was on the increase, after which it gradually decreased; it was lowest at the two ends of the day. What was the reason of this? Does the aliment taken an hour after rising in the morning, lay the foundation of the increasing powers? or is such a process merely dependant on a natural law? To settle this, the hour of meal-eating was changed; breakfast, which had hitherto been taken at eight o'clock was deferred to half past ten. The dynamometer was then used at seven, half-past nine, and ten o'clock; the average of the three periods shewed that in the interval, and without taking any nourishment, or the intervention of any appreciable exciting cause, the strength had progressively increased. Therefore, it is plain that when fasting, a progressive increase of muscular power occurs during the major part of the morning, without any other excitation than the natural play of the organs, and the mild action of external agents. Further experiments, however, shewed that after breakfast the dynamometer was raised 7°, evidencing that though the increase of power is independant of, it is still aided by the ingestion of aliment.

[Many experiments made by M. Edwards on the privates of a regiment, are related in this portion of his memoir; we shall, however, content ourselves with the conclusions he draws from them regarding the influence of aliment on the muscular powers: they are as follows.]

It may therefore be established as a general rule, that there is an augmentation of muscular power in some men after every meal that is composed of good materials: and there is every reason to suspect that the exceptions observed were owing to the fact of some of the subjects of the experiments not being sound men (*hommes forts*). To

verify the point, similar experiments were made on persons that were unsound either from disease or from age, and the results were the converse to those remarked in the soldiers. In individuals therefore who, in proportion to their age, are relatively debilitated, and have still a nominal constitution, there is a general decrease of muscular power immediately after eating; but this descending tendency is far less pronounced than the contrary tendency, which is found under similar circumstances.

This contact between the immediate effects of food on the muscular powers, according to the soundness or debility of individuals, is worthy of attention. The elevation or depression of the powers which follows the ingestion of aliments is, as it were, instantaneous; it is the consequence of a passing contact, and altogether distinct from the subsequent effects of digested food. This operation commencing immediately after the arrival of food in the stomach, tends to concentrate there the powers of the individuals, and consequently to counterbalance the other effect. Two opposite tendencies therefore obtain after the ingestion of aliments, and it is the difference between them that the dynamometer makes known; this difference is minus in feeble and plus in vigorous persons. If the quantity of aliment is moderate, the call of the powers towards the stomach will be less, whilst the excitation produced by the contact will be the same as if the meal had been larger. We may then imagine cases wherein, after taking soup, the development of the muscular powers shall be greater than at the end of the meal. This excitement is also greater after dressed than after simple gelatine.

* * * * *

It may therefore be laid down as a general proposition, that the intensity of the action of gelatine on the muscular powers tends to increase with the proportion of this substance; whence it would follow, that soup made with two ounces of gelatine and a pound of meat would act more energetically on the muscular powers than common soup made from four pounds of meat. The strengthening influence of gelatine by itself, has been confirmed by another result, namely, that the fortifying action of soup with the maximum of gelatine, has not only greater intensity but also lasts for a longer period; for it must not be supposed that the terms, intensity and duration, are always connected.

—*Gazette Medicale*, Feb. 21, 1835.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Cancer of the Penis—Amputation.

MARCH 10TH.—A healthy-looking man, apparently of about forty years of age, was

brought into the operating theatre, having laboured under cancer of the penis for seven months. The disease commenced, as generally is the case, in the shape of a purplish livid tubercle, situate on the glans penis, which had rapidly involved the whole of that structure, and extended to the prepuce, which latter thickened, everted, and retracted, tightly embraced the cervix of the glans, thus producing, as the operator afterwards remarked, a troublesome form of paraphimosis, which was very general in these cases.

The open carcinomatous ulcer had quickly succeeded to the first stage and spread over the whole diseased surface.

The operation of amputation having been decided upon by the surgical staff of the hospital, the case afforded Mr. Cutler, the recently elected assistant-surgeon, an opportunity of making his first appearance before the pupils of the hospital in the character of an operator, and we can hardly refrain from taking this opportunity of saying that the intrepid and surgeon-like manner in which the operation was gone through reflected the highest credit upon the operator; and without any desire to make the least invidious comparison between Mr. Cutler and his opponents at the late election, we must say that we think the governors of the institution have every reason for gratulation in possessing the services of this gentleman.

A fillet of broad tape being first passed once or twice around the root of the penis, in order to prevent unnecessary hæmorrhage, its ends were held by Mr. Hawkins, whilst Mr. Cutler, taking the glans penis in his left hand, and slightly extending the organ, divided it with one stroke of the knife about an inch and a half from the pubes. Upon slightly relaxing the fillet, the mouths of the vessels in the stump were readily discovered, and ligatures at once applied to them, about six in all being requisite. A catheter of elastic gum was introduced through the urethra into the bladder, its extremity being cut off about an inch from the opening; the skin was then drawn over the stump and secured by two stitches of suture. The catheter was secured in the bladder by means of the ordinary apparatus of fillets and tapes employed for that purpose, and its mouth closed with a wooden peg. We have seldom witnessed a catheter secured in the bladder in a more dexterous and neat manner.

After the patient had been removed to the ward, Mr. Cutler gave a short account of the history and progress of the case. A section of the amputated portion of the penis having been made, it was found to present the usual characteristics of scirrhus in an ulcerated state, involving the whole of the glans and prepuce, but not extending far beyond these parts, though, to our eye, the fibrous tunics of the cavernous bodies appeared somewhat hypertrophied even at the point of division.

It is to be hoped that the disease will not return in the stump; but we understand that Sir B. Brodie, who has operated in about twenty cases, says that he only recollects two in which this unhappy result did not occur.

—o—

WESTMINSTER HOSPITAL.

Stricture of the Urethra.

EDWARD CORMACK, aged 38, was admitted into Northumberland Ward, March 2nd, under the care of Mr. White. He appears to have led an irregular and dissipated life, and had stricture of the urethra seven years ago, which, however, had been so far successfully treated as to permit a free passage to a small stream of urine, except when he was under the influence of a debauch. He admits that he has been drinking to excess, more or less, throughout last week, but that on Saturday he made himself completely drunk with spirits and beer. On the Sunday morning he found that he could not pass his water, unless in drops, and by Monday morning the retention had become complete. He applied to a neighbouring apothecary, who endeavoured to pass a bougie, but without effect. He came to the hospital about noon, and Mr. Thompson endeavoured to pass, first a small silver catheter, and afterwards instruments of catgut and elastic gum, but without success. A warm bath was now ordered, and the patient placed in it, and the instrument then tried, and the bath was thrice repeated, but with the like result. Venesection was now had recourse to, and twelve ounces of blood were drawn from the arm; and after an interval had elapsed, the attempt to pass the catheter was also repeated, but even in the state of relaxation and exhaustion in this way produced, no instrument could be passed. The endeavours of Mr. White, who came about midnight, were attended with no greater success; it appeared that there was a false passage in the muscular portion of the canal, which added greatly to the difficulty in attempting to introduce the instrument. Mr. White and Mr. Thompson consulted as to the propriety of puncturing the bladder from the rectum; it was, however, agreed to wait until the morning; a suppository, of four grains of solid opium having been directed to be administered.

3rd. The patient is somewhat relieved this morning, having passed a little urine gutta-tim. The tumefaction and tension in the hypogastric region, which existed yesterday, is not however in the least diminished, and appears to be still more sensible to pressure. The blood taken away at the first venesection yesterday does not present any appearance of the buffy coat, but that of the second is highly buffed and cupped. He was ordered an enema containing 2 drachms of liquor opii sedativus, 2 ounces of castor oil, and a

pint of gruel, which has been administered, and has afforded him additional relief, but no instrument can yet be introduced. He is ordered to take at bed-time 15 grs. of Dover's Powder.

4th. He has been somewhat relieved by passing about a pint of very high-coloured urine, in drops. He is able, by actively assisting in its expulsion, to pass a little in a very small stream, but this occasions him excessive pain. His mouth is sore, and breath very offensive; it now turning out that he is under the influence of mercury, having both been rubbing it in and taking it internally before his admission, for a chancre.

There is a very considerable degree of swelling above the pubes, which is very tender on pressure. The tongue is covered with a thick creamy fur; pulse 96, full and soft. He had some castor oil yesterday, which has freely relaxed his bowels. He is ordered a suppository of 5 grs. of opium at bed time.

5th. He continued to pass water guttatim until about 2 p. m., when he had a severe attack of pain, and found himself unable to expel a drop.

Mr. Snowdon, the house-surgeon, being called to him, procured a warm bath, which gave him great relief, and enabled him to pass a little water.

The retention, however, has returned in its most unmitigated form during the day, and the hypogastric tumour evidently increases in size. The general health, however, is not so much affected as might have been expected; nor is the countenance expressive of any great degree of anxiety; the pulse is 84, and not so full. The smallest elastic gum catheter that could be procured was endeavoured to be passed, both by Mr. Thompson and Mr. Guthrie, but without success; it was therefore passed into the urethra as far as practicable, which was just beyond the triangular ligament, and was left there, being secured to the penis with threads and adhesive plaister.

6th. This morning, between the hours of six and seven, he has passed, guttatim, about a quart of very high-coloured urine, but since that period he has not been able to pass a single drop. The tumour in the hypogastric region has much increased in size; it extends to the umbilicus, and is well defined. Mr. Thompson again endeavoured to pass the instrument, but ineffectually; he therefore determined to try the effect of a tobacco-enema, which was ordered to be prepared. The countenance of the patient has a more anxious expression, and altogether he is not so well.

7th. He has been somewhat relieved since yesterday, by passing about three pints of urine in frequently repeated drops, but he cannot pass any in a stream. The tumour in the hypogastrium is, however, much the same as before. The tobacco-enema reduced the muscular power considerably; and, al-

though it did not enable Mr. Thompson to pass any instrument, yet he thinks it was useful, and that it enabled the patient to pass more water than he otherwise would have done. Mr. Guthrie considers that this case confirms an opinion for which he has contended; viz. that the peculiar manner in which the ureters enter the bladder is a provision of nature, against excessive distention of that viscus, a moderate degree of distention producing a mechanical closure of the openings of these canals, and thus preventing the further admission of urine, which hence accumulates in the ureters and pelves of the kidneys, which become proportionally dilated, and afford temporary reservoirs until the obstruction in the urethra is removed, and the fluid can find its way into the bladder*.

9th. Much better. He discharges the urine very freely, and without much effort, as it even drops from him when asleep. However, he passes it only in drops, though these quickly succeed each other. There is now but very slight tenderness over the pubes; the pulse 80, and regular. Altogether he now appears to be going on well.

11th. He is now able to pass his water in a stream, though a small and interrupted one; he has but little pain, and passes about three pints daily. His general health is pretty good, though but weak.

14th. Much improved since last report; the vesical tumour has altogether disappeared, and the urine continues to pass with the same and even a greater degree of freedom.

16th. Continues improving; but no instrument has yet been passed, nor has it been attempted during the last four days.

Diseased growth of the Clitoris and Nympha.

Previous to a leg being removed by Mr. Thompson, a female was brought into the theatre, to have an enlarged and diseased nympha removed by Mr. White. It appears that the disease is of long standing, and that a great portion of the clitoris and the nympha of the opposite side had been removed at a previous operation some time since. Upon the parts being exposed, the labia majora were found to be greatly tumefied, as if from an œdematous condition of this tissue, and the skin of the perineum extending beyond the anus and to the inner part of the thighs, was of a highly livid colour, and in some parts apparently disposed to ulcerate. Within the labium of the left side, and occupying the whole of the genital fissure, was seen a large oval tumour, about the size of a hen's egg; its surface was intersected by numerous lineal depressions of its tegument, which was of a dirty flesh colour. Its general appearance was hence similar to that of one of those condylomatous tumours, resembled

* Vide Guthrie on the Anatomy and Diseases of the Bladder and Urethra. London, 1834, pp. 6—8.

risen to 100 ; bowels open. He was bled again to $\frac{3}{4}$ xvj, and 15 leeches were applied to his face ; five grains of calomel were given at night, and the senna mixture the next morning, when his pulse had fallen to 96 ; the redness now began to leave the face and spread itself over the scalp, and he became slightly delirious ; this was an unfavourable symptom—it is true that many persons who are delirious recover, yet, generally the cases are fatal. So long as the intellects are clear, though the inflammation be very severe, your prognosis may be favourable ; when the inflammation spreads, and delirium come on, it is unfavourable. The head was shaved and fomented, and the swollen parts of the eyelids again punctured. Tartarized antimony in $\frac{1}{4}$ gr. gradually increased to $\frac{1}{2}$ gr. doses, were given every two or three hours.

12th. More delirium ; pulse 120 ; erysipelas of the face nearly gone ; discontinue the tartarized antimony, and as there is great debility, give him a mixture containing the carbonate of ammonia.

13th. Delirious all night.

Muriat. morphiae. gr. i, statim.

The erysipelas extending to the back, we drew a line across with nitrate of silver, in order to stop its progress ; it was not, however, attended with any benefit. Mr. Chandler, the house-surgeon, thought this arose from the line being too near the diseased parts ; nitrate of silver is often efficacious in stopping the extension of the disease.

15th. There is great difficulty of breathing, with inflammation of the fauces and uvula, the mucous membrane of which shews a slight vesication containing a serous fluid. It is possible the inflammation might have extended from the face to the throat ; Baron Duputyren mentions several cases in which this occurred, so that those who maintain that erysipelas only affects cellular membrane are mistaken. John Hunter did not think it confined to the skin, but looked on every species of inflammation which tended to spread, as erysipelatous. Ordered to inhale the steam of hot water. At half-past eleven, P.M. the breathing became more difficult, and he died suddenly, apparently from suffocation.

Dr. Carswell is preparing the parts of the throat affected, or I should have had them here for your inspection. Mr. Liston however, who has seen several cases of the kind, had this drawing taken (shewing it), of the state of parts in a case semilar to the present one, only more advanced. You will perceive in this drawing, that there is pus under the mucous membrane of the glottis ; ours only had a serous effusion in the same situation, but a small quantity of pus ; in the cellular tissue outwardly to the thyroid cartilage, also considerable inflammation of the mucous membrane of the trachea. On opening the head, the vessels of the brain were found full of black blood, but no other symptoms of disease was present. The left ventricle of the heart was distended with black blood, shewing the immediate cause of death was suffocation. The most important circumstance of the case is the disposition to inflammation of internal parts, that exists in erysipelas : after death you will find inflammation in some of the deep-seated organs, as in our case, though the erysipelas be apparently cured. Had we been aware in the early stage that disease had existed in the throat, we should have left the erysipelas to itself—and I do not think we should have given stimulants. Had tracheotomy been performed it might have saved the patient for a few hours, but would not have been attended with any ultimate benefit.

SATURDAY, APRIL 4, 1835.

VOL. VII.

LECTURES
ON
MEDICAL JURISPRUDENCE,
DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,
At the University of London; Session 1834-35.
LECTURE XXIII.

GENTLEMEN—The next subject, *Public Health*, to which I have to direct your attention, is one of general interest, and, were it fully entered into, would itself be sufficient for a separate course of lectures. The nature of this course does not permit me to bestow upon it the time and consideration which it merits; but, nevertheless, it cannot be passed over in silence.

The object of every government is the happiness and welfare of the people; and, consequently, the maintenance of the health of the community may be justly regarded as one of the functions of a government. In many states there is a separate code or system of laws for this purpose; but, in this country, except on some particular emergency—such as, for instance, when the Asiatic Cholera visited our shores, and in the enforcement of the quarantine laws, our government scarcely concerns itself with the health of the people. The individual interests of Englishmen, however, have effected what the government has neglected; and our cities and towns are as healthy, if not more so, than many of those cities in which every thing connected with their salubrity is a matter of legal enactment. Our towns are amply supplied with pure water; the streets are cleaned, and drainage is attended to; and, following the example of some of our continental neighbours, we are, at length, about to remove the places for the interment of the dead from the midst of the population to cemeteries at a distance from the towns. That the exhalations emitted from churchyards are, to a certain degree, injurious to the health of those in their vicinity has been demonstrated by ample experience, particularly if the district be a populous one and the opening of the graves frequent. But even the improvements which are anticipated on this subject, are not the work of govern-

VOL. VII.

ment, but have originated as matter of speculation with individuals: indeed, as I have already said, with the exception of the quarantine regulations, and the Central Board of Health lately established, England may be regarded as devoid of *medical police*.

The defect of medical police, however, is in some degree supplied by the laws against nuisances, and as far as these are connected with health, they become subjects of medico-legal inquiry; and much depends on the evidence afforded by the physician, in finding a verdict in such cases. Whatever inconveniences, hurts, or damages, is a nuisance in the eye of the law: they may therefore, be regarded as affecting both animate and inanimate. The latter only comes within the sphere of the medical practitioner; the former is intimately connected with his professional duties. Any person who fixes his abode near a very obvious nuisance must abide the consequences, and cannot be legally indemnified for any inconvenience or injury which he may sustain; but if the nuisance be one which is not very obvious to the senses, and yet injurious to health, no speculator has a right for his own benefit to establish any manufacture in a neighbourhood, which may endanger either the property or the person of his neighbours; and, therefore, those aggrieved have a right to compensation at law: but, at the same time, in a country like ours, the prosperity of which depends on enterprize and commercial advantages, these must not be checked by capricious or arbitrary objections. In cases, therefore, in which the health or personal comfort of individuals is supposed to suffer, medical evidence is called in to determine the extent and nature of the injury sustained. The necessity, therefore, for the medical practitioner to make himself fully acquainted with the influence of every cause of disease, arising from what the law terms nuisances, is sufficiently obvious. My learned colleague, however, will inform you that there are exceptions depending on custom, and that the law does not consider many real nuisances actionable, even in the most populous districts, provided they have existed before any buildings were erected near them. But

even in such cases medical opinions may be required; and our business is not to determine on the propriety of the law, but on the degree of insalubrity of the nuisance.

Nuisances may be arranged under four heads:—

1. Manufactories or trades which produce noxious effluvia, insufferable either from the noisomeness of their odours, or which are the source of diseases.

2. Shambles, or slaughter-houses.

3. Drains and outlets of waste liquids which may poison neighbouring streams.

4. Infections.

The first set of nuisances, those connected with trades and manufactories, may be subdivided into—1. such as afford hurtful effluvia, the result of putrefaction, as animal decomposition by heat: 2. such as evolve much smoke, and carbonaceous matters: and 3. such as diffuse gases, which, mingling with the atmosphere, become injurious to health when inhaled into the lungs.

Almost all vegetable and animal substances, placed under some circumstances, when deprived of vitality, supplied with moisture, and exposed to air and a certain temperature, undergo the putrefactive fermentation, the products of which, injurious to health, are carburetted and sulphuretted hydrogen, carbonic acid, and nitrogen. The two first operate upon the living system as sedative poisons; the two latter cause asphyxia; and there are numerous instances on the records of medicine, of diseases produced by these effluvia operating upon the body. All occupations, therefore, which give rise to such effluvia are truly nuisances, and should be performed without the limits of cities, and at a distance from human dwellings.

The preparation of hemp and flax affords a nuisance of this description. In order to free the vegetable fibre from the other parts of the stems of the plants, in making hemp and flax, the plants are placed in pools or fosses dug for the purpose, until such time as putrefaction is produced and proceeds to a certain point; the odour of the effluvia which exhales is most noisome, closely resembling that of bilge water in the hold of a foul ship. Even when this process is conducted in the country, at a distance from houses, diseases sometimes occur from it, such as fevers of a remittent and intermittent character. At Helmsedt, the flax is steeped in the Aller, and, annually, produces an epidemic dysentery which prevails for several weeks during the autumn. Lancisi ascribes some of the fevers which rage at Constantinople to the fermentation of the moist hemp brought from Cairo and stored in granaries during the summer months; and instances are on record of malignant fevers originating from this source. Some parts of the process of tanning is equally deleterious, especially that part which subjects the hides to incipient putrefaction, in order

to loosen the epidermis and enable it and the hair to be more readily separated from the true skin, which is to be converted into leather. The making of catgut, purifying fish oil, butcher's stalls, cabbages and other vegetables left in markets to putrify, and accumulations of filth behind houses, are all properly legal nuisances, and in prosecutions regarding them the decisions rest chiefly on medical evidence. Some trades necessarily produce effluvia of the most offensive kind: such as varnish-making, the unfolding of horns by means of heat, soap-boiling, and such like, which are almost as injurious to health as putrefaction, and, therefore, are deservedly regarded as nuisances. In varnish-making, in particular, the stench is sometimes so great, that the workmen have fainted: and on one occasion two men actually lost their lives in a manufactory of varnish in Gray's-inn-lane. But some employments are productive of offensive odours, such, for example, as rendering tallow, that is converting fat into tallow, and making candles, which on many nervous and irritable habits cause nausea and headache, and are regarded as nuisances in the eye of the law: nevertheless, they cannot be said to be actually injurious to health. In actions, therefore, brought in such cases, if it be necessary to procure medical evidence on either side, it behoves you to draw the distinction between a state of full health and one of delicacy or actual disease, in delivering your opinions respecting the influence of offensive odours on the health of the community.

All manufactories and trades which require the consumption of much coal, and emit large volumes of smoke, are also injurious to health, but certainly in a less degree than those in which putrefaction takes place; and if we consider the comparative healthy state of this metropolis, with that of other cities of a much less extent, and then take into account the immense quantity of carbonaceous matter constantly floating in the atmosphere, we cannot regard smoke as a source of general unhealthiness. It has been demonstrated that the quantity of smoke thrown into the atmosphere from fires of equal size and consumption of coals, is in the inverse ratio of the height of the chimneys. When these are very high, much of the carbonaceous and other matters, which would otherwise escape into the atmosphere, are condensed in the chimney; thence in delivering opinions respecting the unwholesomeness of breweries, distilleries, glass-houses, and other erections, giving off much smoke, the elevation of the chimney must always be inquired into, and the inference drawn accordingly, on the principles which have been just mentioned. The same reasoning applies, also, to some manufactories in which large quantities of foetid vapours are evolved; as, for instance, in the manufacture of Prussian blue. In this process,

the distillation of animal matter with impure potassa extricates most offensive vapours, which are, nevertheless, not injurious to health. Such works, however, are justly regarded as nuisances: but if the chimnies be carried to a height of 150 or 200 feet, no inconvenience arises, as the offensive vapours are dissipated in the air.

Gases are more deleterious, even when largely diluted, than smoke, and therefore, in a medico-legal point of view, those manufactories which give them off are greater nuisances than those which are regarded as such, only on account of the great quantity of smoke which they create. The manufactory of sulphuric acid, in this country, is of this description, owing to the careless manner in which much of the materials is allowed to escape into the air, in the form of sulphurous acid and nitrous acid gas. Much inconvenience and injury to health arises from breathing these gases; but an action against the erection of a work of this kind may be vexatious; and, if the effects have not already been felt, and the evidence of a medical man is brought forward to prove the insalubrity of such a work, you must bear in recollection that it is only insalubrious from want of due precaution; and that works of this description may be carried on in the midst of a populous town, or a city, without the least injury to the health of the population. This gas, however, may prove injurious to a neighbourhood when extricated abundantly in cementing iron-work, which is sometimes done by a compound of muriate of ammonia, sulphur, and iron-filings. A case of this kind occurred in 1821, at Maidstone. A workman was repairing the inside of a boiler of a steam-engine with this cement, and was suffocated; his assistant, in descending to his aid, inhaled the fumes and also fell to the bottom. Water was thrown into the boiler to absorb the gas, and the bodies taken out; one of the men was quite dead, and the other died next morning. With respect to nitrous gas, issuing from the works for making aquafortis, nothing insalubrious attaches to it; on the contrary, in the highly diluted state in which it is found in the atmosphere, it may be breathed not only with impunity, but with advantage: and the same observation applies, even in a greater degree, to manufactories of bleaching fluid, in which much chlorine is extricated, and escapes into the surrounding atmosphere. At the same time it must be recollected, that strangers going into such works may suffer, and that fatal effects have occurred to the workmen in them, from accidents extricating such quantities of the gases as to affect powerfully the mucous membrane of the trachea. Under such circumstances, therefore, these gases cannot be regarded as innocuous. In Curvisart's *Journal of Medicine*, a case is detailed by Dr. Desgranges, which is copied into the 3rd. vol. of the

Edinb. Med. and Surgical Journal, p. 16.—(Read). In the same manner chlorine may prove fatal; but in the degree of dilution in which they are usually found within the manufactories, even they may be breathed with impunity. Mr. Tennant, of Glasgow, the greatest manufacturer of bleaching materials in this country, informed me that men who go to engage themselves to him, labouring under pulmonary diseases, lose their coughs if they be taken gradually into what is called the chlorine house; and that people labouring under consumption of the lungs frequently take lodgings in the neighbourhood of his works, for the express purpose of inhaling the highly diluted gas.

In coal gas works, much of the mixed gases occasionally escape, and are extremely offensive; but, although I am of opinion that this mixed gas operates as an injurious agent, when inhaled by those not accustomed to it, yet farther experience is required to prove this opinion. It must be admitted that gas-men breathe it in a much less diluted state with impunity; but it is not easy to limit the extent to which the body will accommodate itself to the most deleterious influences, when gradually subjected to them. Sanctorius relates a curious case of a criminal who fell sick when taken out of a noisome dungeon, in which he had been long confined, and could not be recovered until he was restored to the impure air in which he had long breathed.

Brick and lime-kilns exhale carburetted hydrogen gas, and carbonic acid gas, and consequently prove injurious to persons who fall asleep on them; but they cannot be regarded as nuisances if the insalubrity of these gases, in the greatly diluted state in which they are spread over neighbourhoods; but as a nuisance in the eye of the law comprehends "anything which worketh hurt, inconvenience, or damage," they may be prosecuted as such; but, in giving evidence as to their unwholesomeness, you must keep in view the facts which I have just mentioned.

The second set of nuisances, legally considered as such—shambles and slaughter-houses—are undoubtedly the sources of diseases and mortality when the offals are not regularly removed; for when the filth is collected in heaps and left to putrefy, the same effects result as in the first set of nuisances to which I directed your attention. Fevers, and even those of an epidemic kind, are engendered. Orfila applied putrid animal matters to wounds in dogs and other quadrupeds, and found that death generally ensued in less than twenty-four hours: extensive local inflammation and constitutional fever were induced. There is an Act of the 57 George III. expressly enacting a penalty for slaughtering animals in or near any street; but this still takes place behind the houses of private butchers; nevertheless, by regularly removing the

offal, no inconvenience is felt in the neighbourhood. The trade of a butcher, when cleanliness is attended to, is rather healthy, at least few people appear to possess more vigour of frame, and even in large towns seem to enjoy greater health than the servants and apprentices of butchers, who are constantly surrounded with fresh carcasses. Thus I have never seen a butcher suffering from phthisis; nor have I ever met with a medical man who has witnessed the disease amongst this description of people. I cannot pretend to account for this circumstance; but the fact is undeniable.

With respect to the third description of nuisances—foul drains and cesspools—there can be only one opinion. These operate in two ways; by the exhalations arising from them infesting the atmosphere with the miasma of disease; and by carrying poisonous matters in a fluid state into wholesome streams. When a drain is obstructed, from much filth accumulating in it, it becomes a source of miasms the same as arise from stagnant pools, but more destructive, owing to the greater quantity of animal matter contained in the mud. The exhalations are chiefly those of ammonia, sulphuretted hydrogen gas, and carburetted hydrogen gas. When these mixed gases are inhaled, the effect is sudden weakness and insensibility, and all the symptoms of asphyxia, terminating in immediate death; but when these gases are more diluted with atmospherical air, the effects are nausea, colic, imperfectly defined pains in the chest, and lethargy. Many instances of fatal cases from such exhalations are detailed in a work by M. Hallé, entitled, "*Recherches sur la Nature du Mephitisme des fosses d'aisance*, 1785." Analogous accidents have arisen in this country from clearing out drains; and it is of importance in all such cases to ascertain the presence of sulphuretted hydrogen, before a workman ventures into a foul drain, by carrying or rather letting down into it a piece of paper moistened with a solution of subacetate of lead, or even merely rubbed over with the dry carbonate. If the gas be present, the paper will be stained of a deep brown. Dupuytren ascertained that air containing 1-1300th of this gas will destroy a bird in a short time; that which contains 1-800th produces death in a middle-sized dog; and a horse dies in an atmosphere containing 1-250th of it. In 1828, twenty-one boys at a boarding school at Clapham were suddenly seized with alarming symptoms of violent irritation in the stomach and bowels, subsultus in the muscles of the arms, and excessive prostration of strength. This was attributed to a drain exhaling sulphuretted hydrogen gas, and it is probable that this was the true source of the disease. During the prevalence of typhus in Paris, in 1814, M. Iadioux remarked that the mortality in the Hospital Salpêtrière was greatest in those wards near the sewers.

When streams or springs are contaminated with the water of drains, the injurious effect upon the water can always be determined by its influence on the fish contained in the stream: if they die, the water is certainly unfit for the use of man; but much filth may flow into a river or stream, and render the water disgusting, without so far contaminating it as to injure health. This is the case in the Thames, into which all the drains in this vast metropolis empty themselves, yet the water, when filtered, is as wholesome as any obtained from the purest springs. This depends on the vast body of water, and the constant change which it is undergoing, so that the poisonous contents of the drains are rendered inert by dilution, in the same manner as the poisonous exhalations emanating from some manufactories are dissipated in the atmosphere by means of high chimnies. But the same reasoning does not hold with regard to tanks and stagnant water, or wells into which imperfect drains may pour their contents by filtration, and render the water not only merely insalubrious, but poisonous. Such limited collections of water may also be actually poisoned by vegetable poisons thrown into them—a circumstance not uncommon in Oriental countries, and one which would have proved fatal to a large detachment of the British army in the Burmese war, had it not been prevented by the knowledge and activity of Dr. Wallich. In one tank of water destined for the use of the army, in a halt in pursuit of the retreating Burmese, the water had been poisoned by the *aconitum ferox*, bruised and thrown into the tank by the enemy, before they evacuated the place. Fish-ponds are sometimes poisoned, in this country, by the blue vetch, *ricia lathyroides*, a transportable offence by a statute of 7 & 8 Geo. IV.

Public hospitals for the cure of the sick and maimed poor are the proudest boast of Christianity, and the most distinguishing feature between the mild and benevolent faith of our Redeemer and the cruel rites of Paganism. They have, nevertheless, been frequently regarded as nuisances, and actions have been brought to put them down. Whatever may be the law upon this subject, and upon this point, my learned colleague will fully satisfy you, it is proper that you should be aware that even hospitals erected expressly for the reception of infectious fevers, are not likely to spread infection in a neighbourhood, if only ordinary attention be paid to cleanliness and ventilation. This fact was clearly demonstrated in the early period of the House of Recovery at Manchester, and it has since been confirmed at other places. Speaking of the House of Recovery at Manchester, Dr. Ferriar has recorded the following important observations in his *Medical Histories and Reflections*:—"During several years," says he, "we were limited in space, and unable to receive the whole num-

ber of patients whom it was expedient to receive. Some adjoining and neighbouring houses were therefore occasionally engaged in the same street, for the admission of patients; and thus, without any previous intention on our part, a set of experiments was made respecting the distance to which contagion will extend. In the first instance, no persons suffered in the neighbouring buildings, where the street was only four yards wide, the windows of the occasional fever-ward being generally open, and the house full of patients. In another instance, a house capable of containing twenty-five patients, not at all separated from the houses in the adjoining row, was used for twelve months as a fever ward, without the occurrence of fever in the immediate neighbourhood. Thus the *experimentum crucis*," continues Dr. Ferriar, "has been tried, and the innocence of contagion, when properly diluted with atmospheric air, is fully established." This is a most important fact, and ought never to be lost sight of in every instance where medical evidence is required on any question which may be raised respecting the insalubrious influence of an hospital on a neighbourhood. It is also necessary to remember, that the influence of pure air and ventilation in weakening the power of contagion, does not depend on its acting as a neutralizer or destroyer of the virus, but merely by diffusing it through an extensive space, it is so diluted as to be rendered harmless; for it is not the impure air of an ill ventilated hospital which adds to the greater contagiousness of its wards over those of a well ventilated hospital: it is the concentration of a great quantity of contagious matter within a small space, and the effect of that impure air on the habit, in predisposing it to be powerfully affected by the contagious matter. In every hospital the cases of infectious diseases should be separated from the others, and placed in wards by themselves, by which means the chance of the propagation of the infection is greatly lessened: it is, indeed, astonishing how small an interval is necessary to cut off the influence of a fever in an hospital or a ward, if free ventilation be attended to. In the Vienna hospital the fever ward is separated from that allotted to chronic diseases by a space of six feet only, yet such is the beneficial influence of ventilation, that Dr. Frank informs us there has been only one instance of an individual in the chronic ward being affected with fever; and on investigation it was discovered, that in this case it was occasioned by the sufferer having visited a friend in the fever ward. Keeping these circumstances in view, there can be no difficulty in deciding how far an hospital may be regarded as a nuisance, or injurious to the health of any neighbourhood. If it be clean, well ventilated, and the cases of an infectious nature are kept distinct from the others, no injury can possibly accrue to

the neighbourhood from such an hospital; it cannot be regarded as a nuisance; but if, on the contrary, it be ill ventilated, the virus may be so concentrated, that, like Pandora's box, when opened, it may be capable of infecting the whole vicinity: in this case it is one of the worst of nuisances.

In closing these brief remarks on hospitals, considered as nuisances, I cannot refrain from embracing the opportunity which is afforded me of referring to the origin of these admirable institutions for alleviating human misery. The first public hospital was erected in the fourth century by a noble Roman lady, by name Fabiola, a Christian by religion, who having regarded herself sinful for having married a second husband whilst her first, whom she divorced, lived, imposed upon herself a solemn penance, converted her estates into money, and built an infirmary, into which sick and distressed objects of every description were collected from the streets. "Many who were afflicted with distempers the most loathsome and offensive she attended in person, carried them in her arms, bathed their sores, moistened the lips of the dying with her own hands, and so tenderly assuaged their miseries, that those who were well almost envied the sick." (Edin. Med. and Surg. Journ., vol. 4, p. 245). This conduct was the result of superstition; but, as it has been well said, "we might pardon superstition itself, if it had never taken a different turn." It is uncertain whether, in the earliest hospitals, there were either physicians or surgeons attached to them. The knights of Jerusalem attended the sick, bound up their wounds, and acted as their physicians; but their art lay in exorcism and the administration of beverages, oil, wool, and cabbage leaves. "They trusted," says Guy de Chauliac, "que Dieu a mis sa vertu aux parolles, aux herbes, et aux pierres." The first mention of the appointment of physicians and surgeons to hospitals is in the statutes of the Knights Templars, under the government of John de Lustie, who, in 1437, as grand master, defined the duty of physician and surgeon in such establishments. In the twelfth century hospitals had so much increased that we are informed by Benjamin of Tudela, that he found many hospitals at Bagdad having nearly sixty shops or dispensaries attached to them, which distributed, at the public expense, the necessary medicines. Were any proof required of the great aid which these establishments have afforded to the improvement of medical science, and consequently to the health of the community, it is only necessary to look into the comparative statement of mortality in some of the British hospitals at different periods. At St. Thomas's, in 1741, it was about 1 in 10; in 1813, 1 in 16; in the Edinburgh Infirmary within this century, it has diminished from 1 in 14 to 1 in 21; and in the fever hospital of Dublin from 1 in 12 to 1 in 20.

But although hospitals, under proper regulations, cannot be regarded as nuisances, yet the exposure of the community to infectious diseases, by people who are infected with them freely intermingling with society, has always been considered as criminal; and therefore laws to prevent it have been at various times enacted. In the reign of James the First, it was made felony for any one to walk abroad in the streets, having a plague sore running upon him; and at this day it is an indictable offence for any person to pass through the streets, or cause others to pass through the streets, even for medical advice, while they have the small pox upon them. A cursory glance at the history of small pox is sufficient to convince us of the wisdom of this law. Soon after the discovery of America, the Spaniards landed a negro slave, infected with small pox, along with the troops under Don Narvaez, who were sent by Velasques from Cuba, in 1520, to seize Cortes, and send him prisoner to Cuba. The infection soon spread through Mexico, and in a very short time three millions and a half of people were destroyed by the disease in that kingdom alone. (Robertson's America, vol. iv, b. 8, note 1). In 1707, the small pox broke out in Iceland, and destroyed sixteen hundred persons, one-fourth of the whole population. It is unnecessary to repeat proofs of the frightful extent to which the disease has occasionally extended itself;—even since the blessing of vaccination was bestowed upon mankind, I have seen the inoculation of one infant with small pox, introduce the casual disease into a neighbourhood, and the mortality spread far and wide. In an action, the King *versus* Taunton, tried in the King's Bench during the last reign, Mr. Justice Bayley delivered the following opinion. "I hope it is sufficiently notorious, that the causing persons to pass through the streets, who may have small pox upon them, although they are going for medical advice to some person in whom they may have confidence, is an indictable offence; and if that person, instead of attending them at their own houses, as he might do, chooses to direct that they shall, from time to time, be brought or come to him, there is no question that he is liable to an indictment". With respect to small pox, therefore, there is no doubt that the exposure of persons in that disease is legally regarded as a nuisance; but, as much risk attends the exposure of persons with other infectious maladies, and as legal questions may arise upon these, it becomes an object of much importance to discriminate those disorders which are infectious from others which are not so. All diseases which can be communicated from persons labouring under them to those who are free from them, are infectious; some are communicated only by direct and immediate

contact, others through the medium of the atmosphere. Among the first, or strictly contagious diseases, I enumerate plague, itch, syphilis, sibbens, frambræsia or yaws, porrigo, *scutulata* and *decalvans*, nolluscum and elephantiasis: among those communicable both by contact and by the atmosphere, may be arranged typhus fever, dysentery, small pox, measles, chicken pox, influenza, hooping cough, scarlet fever, erysipelas, malignant sore throat, and perhaps Asiatic cholera. These diseases are communicable in every season of the year, in pure as well as impure air; in high and in low situations; and many of them by means of fumes preserved in clothes and substances which have been in contact with the sick, although they may have been removed for some time from them. It is true, that all exposed to contagions and infections do not take the diseases; but it is impossible, previously to the appearance of the disorders, to ascertain who are predisposed, and who are not, and consequently the same precautions are requisite as if all were alike liable to be attacked; and it is on this principle that the quarantine laws have been framed.

In tracing the history of mankind, we find that diseases have arisen, which have diffused themselves over large tracts of countries; and, whatever may have been the source whence they originally sprung, have been carried into, and established themselves in distant parts, either by the passage of those afflicted with them into these parts, or by goods sent from infected places. To prevent this evil, those enactments which have been named quarantine have been framed; and, unless we can disprove the existence of contagion or infection, they cannot be too rigidly enforced. It is contrary to the plan of these lectures to enter minutely into the consideration of contagion; I must take it for granted that diseases are communicable, and can be imported; and, consequently, that quarantine laws are necessary.

It is uncertain when laws for preventing the introduction of communicable diseases were first adopted. The Levitical law contains certain regulations for preventing the extension of leprosy and unclean diseases, both with respect to the persons and the garments of the infected: in the works of Ammianus Marcellinus, some hints are given respecting precautionary measures necessary to be observed to prevent the spreading of contagion; but there is nothing in the works of the early Greek and Roman writers to authorize any opinion that such measures were adopted by them. The first establishment of quarantine is generally believed to have been effected by the Venetians in 1484; and a council of health, consisting of three noblemen, with the title *Sopra la Sanità*, was instituted by them in the following year. The principal business of this council was to inspect the lazarettoes erected in certain places at some distance from Venice, and in which it was required

* See Russell, p. 11.

that all persons and merchandize coming from suspected parts should continue a stated time, fixed by the laws. The example of the Venetians was followed by other countries, as it became more obvious that plague and some other diseases did not originate in some of the parts where they appeared; and the different Governments of Europe resolved that all ships arriving from countries where contagious distempers were known to be frequent, should be admitted only when they brought properly authenticated documents to prove that the country whence they came was free from any contagious distemper when they left it. These certificates are called bills of health, and are distinguished by the terms *clean* or *foul*, as the place where they are obtained is in a healthy or an infected state; and according to their import in this respect the ship and crew are permitted to enter the port and trade, or are forced to perform *quarantine*. Brownrigg, in his work intitled "Considerations on the means of preventing the communication of pestilential Contagion," affirms that the first bills of health were written in 1665, by the consuls of the different commercial nations; but Zegata, in his *Cronica di Verona*, asserts that they were first established in 1527, when the plague a second time made its appearance in Europe. The term *quarantine* implies a period of forty days; and, although Beckman has suggested that this period seems to have been chosen from the idea of the ancient physicians respecting the critical days of many diseases, and the fortieth days was supposed to be the most extreme, yet the origin of this period is by no means well ascertained. It is a curious fact, all these precautionary means against infection were neither invented nor proposed by physicians, but ordered by the police, contrary to their theory.

By an Act of the 26th of Geo. III. which repealed all former laws on this subject, it is enacted "that all ships and vessels, as well his Majesty's ships of war as all others, coming from or having touched at any place from whence his Majesty in council shall have judged and declared it probable that the plague or any other infectious disease highly dangerous to the health of his Majesty's subjects, may be brought; and all ships, vessels, or boats, which may have received any persons, goods, letters, &c. from such vessels, &c. shall be considered liable to quarantine within the meaning of the Act, and to any order of the King in council, published by proclamation in the London Gazette." The penalties for neglect of quarantine are severe. (Russell, p. 111.) The privy council is also empowered to direct, in cases of any highly infectious disease, the destruction of the clothes and bedding of persons dying of such diseases; and to take measures to secure the purification, fumigation, and ventilation of their rooms and houses.

The wisdom of these enactments cannot be doubted; and it is only to be regretted that they are so often evaded, and that infectious disorders are introduced in spite of the utmost rigour of the law. There can be only one sentiment respecting the hardship which they impose upon the uninfected coming from infected places; but the good of the few must yield to the benefit of the many.

When a ship arrives at a port from a suspected place, a boat is dispatched to inquire whether she have any sick on board, and into the nature of her bill of health; but no person is permitted either to go into the vessel or to leave her. If she have any one ill of plague on board, and intimation of this be not given by the captain, he is guilty of felony. On ascertaining the state of the health of the crew, the vessel is ordered into quarantine, according to the nature of her bill of health. In this country, the law in this respect is executed with great laxity; but in the ports of the Mediterranean, and the Adriatic, it is rigorously enforced; and there are lazarettoes of different kinds where the quarantines are performed. If the ship have any of the crew with symptoms of plague, the highest degree of rigour is enforced, and the quarantine continues for eighty days; the goods, before being landed even in the lazaretto, are exposed on the decks of lighters for twenty days, and daily turned. They are then landed, unpacked, and according to their nature exposed to the air. If cotton be part of the cargo, the bales are taken to pieces, and men who are employed for the purpose, throw the whole daily over their heads, for sixty days, and if plague be not communicated to any of them in that time, the cotton is declared clean, and permitted to be taken from the lazaretto. The crew are also confined to the lazaretto, and daily inspected by a medical practitioner, who judges of their freedom from the disease by making them beat their axilla and groins, and observing whether they express any degree of pain; in which case, they are stripped naked, and carefully examined.

If no symptoms of plague have actually appeared on board the ship, and she merely come from a suspected port, then she is ordered to the second description of lazaretto; and the treatment, although nearly of the same kind, is less rigorous. The labourers, instead of throwing the cotton, for example, over their heads, merely bare the arm, and thrust it into the bale, in a naked state, up as far as the shoulder. Twenty days are a sufficient trial in this case, during which, if no disease appear, both the goods and the crew are declared clean. In the third description of lazaretto, the goods are merely landed, and the crew detained for the space of twenty or forty days, as circumstances are more or less favourable. The last kind of lazaretto is a place merely for those sus

pected of having come from an infected port, in which the crew are confined for a week; and, if nothing disadvantageous to their health appear in that time, they are declared healthy. Such is the usual manner of performing quarantine. The services of the medical man are required only to examine the crew and passengers, under the two first species: and in both cases, it is of much importance that he should be aware of the nature of plague and other infections, to be able to decide at once, on the first appearance of the disease. If plague appear during the period of performing quarantine, and the patient die, the body is buried within the lazaretto, and the grave filled with quicklime. Should any of you, gentlemen, be placed in a situation where you are likely to be called upon to perform the duty of inspection, and the state of the pulse is necessary to be ascertained, you should bear in remembrance that the finger should be dipped in oil, so as to interpose a medium between the finger and the skin of the patient: and this has been found a sufficient safeguard to the physician. In examining a patient, also, the practitioner should stand on the windward side of the patient, to afford a chance of the infectious matter emanating from the diseased person to be wafted from him.

The long immunity of Great Britain from plague, has produced much laxity in the administration of the quarantine laws; but it ought to be recollected that goods are shipped for Europe at all times from ports in the Levant, and plague may again appear amongst us when it is least expected. If the experiments of Dr. Henry on the influence of an elevated temperature in destroying the virus of contagion prove available, and there is every reasonable expectation that they may do so, much of the severity of the quarantine laws might be safely relaxed; but, in the present state of the question, the danger of either relaxing or abolishing them is great and obvious.

When danger presses greatly, cordons of troops are employed to prevent any communication between clean and infected places. These consist of soldiers stationed in a circle around the town, at every point by which any person may either pass from or approach the town. The value of such preventive measures is supposed to be fully established; and numerous instances might be brought forth of their apparent sanitary influence; but I will mention one only. The city of Zaripta, which stands in the direct line of the progress of the Asiatic cholera from India, was isolated in this manner, and completely escaped the ravages of this desolating scourge of the present race of man.

The question which naturally arises out of the details which I have thus placed before you, is—in what manner, and by whom is a disease to be ascertained to be such as

to demand the precautions of quarantine, and the other measures usually adopted for preventing its introduction into any country or city? The second part of this query is easily answered—the determination of the character of a suspected disease must be left to the physician; but the manner in which he is to decide the question is not so easily replied to. If I take, as an illustration, the history of the opinions which have been advanced respecting the character, as far as regards its communicable power, of Asiatic cholera, nothing can more strikingly demonstrate the difficulty of arriving at truth, in such an investigation. One set of men of high reputation and undoubted medical learning, maintain that the disease is contagious; others of equal acquirements decide the contrary; how is this diversity of opinion to be reconciled? I confess that I am incapable of solving the difficulty; and, therefore, instead of attempting it, I will endeavour to hold up to you the feeble lamp, from which so weak a ray is shed to guide our footsteps in this obscure labyrinth. Let us take cholera as the object of our inquiry. Is it infectious or communicable? By this term is understood, not simply that it may pass from one individual to another, but that it may pass from persons, or clothes containing its fomes, and be communicated to others through the medium of the air. In arranging the arguments on both sides, we must admit that it must have spontaneously arisen, although we are perfectly ignorant of the circumstances under which this happened.

The chief arguments in favour of its infectious character are the following:—1. It has spread over countries which, in respect of climate, soil, relative elevation, and population, differ greatly from those of the spot in which it first displayed itself. 2. Its progress has been uniform and progressive; often opposed to violent monsoon winds. 3. Bodies of troops in motion have been attacked and retained the disease, while it was unknown to the fixed inhabitants of the country through which they passed: and one of two corps in a camp has been attacked and the other has escaped. 4. Ships arriving from other parts of the world have never suffered before reaching the shore; and in India, the instances of the disease appearing at places immediately after the corps of troops suffering from it, are very numerous. 5. In its progress, cholera has travelled chiefly by the great roads, affecting places on either side, without extending to those situated at a distance from them. This of itself would almost appear conclusive. Epidemic diseases spread extensively over countries; and to use the words of a poet—

— “the circling sky,

The wide enlivening air, is full of fate.”

6. The sick in hospitals, labouring under other diseases, lying near patients ill of

cholera, have been attacked by the disease; servants have sickened after attending their masters, who have died of it; and medical officers in regiments, after intimate intercourse with the sick, have been seized, whilst all the other officers in the same regiment have escaped. Lastly, places surrounded by cordons, and guarded by strict quarantine laws, have escaped, although in the direct progress of the disease. Such are the principal arguments advanced in support of the infectious nature of this disease; let us now examine the contrary opinion. Another fact supports strongly these opinions—namely, the examination of the bills of mortality. 1. The direction in which the disease has progress, has been too uniform to depend on infection. 2. Countries through which troops suffering from it have passed, have remained exempt from the disease. 3. The disease seems to wear itself out in a short time in any place where it has raged, and yet appear with resuscitated vigour on its arrival at another place; where again, however, it is again in a short time stripped of all its fearful qualities, and rendered impotent as before: and thus, to employ the descriptive language of an elegant writer on pestilence, Dr. Hancock, “like some vagabond intruder, who disguises an enormous but short lived voracity under the semblance of impaired appetite, his visits are characterized from place to place, wherever he is permitted to gain a footing in this habitable globe.”

Having thus stated the evidence, the decision ought to follow; but the chain of evidence is incomplete, nor can it be considered as complete, unless we are put in full possession of every circumstance connected with the nature, localities, habits, and police regulations of those places which have suffered, and those which have escaped the ravages of the disease: filth and defective nutriment, hurry and fatigue, anger, intemperance, and the depressing passions, act powerfully as predisposing and accelerating causes of pestilence; whilst the opposite of these conditions, cleanliness, a full and generous diet, temperance, calmness, and regularity, not only operate as prophylactics but as antidotes. These facts are particularly adverted to, gentlemen, to demonstrate to you the importance of topographical inquiries in medical science; the dangers and difficulty of deciding on partial evidence; and the wide field of investigation which lies open before you. In the mean time, in every season of public alarm, it is the duty of the physician, if the smallest doubt exists respecting the real character of a prevailing malady, remaining on his mind, to lean to the side of caution; and if he cannot pronounce decisively, to avoid precipitation in acting; even should contagion and infection be proved to be really bugbears, it is better, in the meanwhile, strictly to enforce the quarantine laws, than

to risk the introduction of pestilent disease in any of the protean forms which she assumes in visiting the guilty abodes of mortals, to draw the incumbent cloud of death over the living.

LECTURES

ON THE

PHYSICAL EDUCATION AND DISEASES OF INFANTS, FROM BIRTH TO PUBERTY,

BY DR. RYAN,

Delivered at the Medical School, Westminster Dispensary, Gerrard Street, Soho;

Session 1834-35.

LECTURE XXXI.

Spinal Deformities in Children, from the Sixth Year to Puberty and Adult Age.

GENTLEMEN—It remains for me to direct your attention to several other congenital deformities; those which occur in childhood, puberty, and the adult age. There is no class of diseases of greater interest to the medical practitioner than spinal complaints, as they are the fertile source of an immense number of nervous and other disorders, which are too often ascribed to other causes.

Spinal deformities are not common to new born infants, but exceedingly so to children from the eighth year to adult age. Every well-informed practitioner knows, that lateral curvature of the spine, excoriation, or hump-back, and incurvation of it, bending inwards, with elevation of one shoulder, must derange the functions of the organs in the head, chest, and abdomen. Teale, Tate, Addison, Barlow, Brown, Copland, Harrison, Griffin, and Beale, have most admirably illustrated this point in their writings, during the last few years. They have shewn that most of the disorders termed nervous, hysterical, digestive, &c. &c. are caused in girls and women, by irritation in the spinal contents, or by curvature of the vertebral column. I daily witness several examples in proof of this statement, in private, hospital, and dispensary practice.

Young girls, from the age of twelve years upwards, and unmarried females, from the adult age, to thirty-six years, very generally complain of pain in the left side, under the false or short ribs, sense of choking, as if a ball were in the throat, (*globus hystericus*), excessive nervousness, absence, or derangement of menstruation, the evacuation being too small in quantity, or excessive, of a dark colour, and accompanied by great pain, (*dysmenorrhoea* or painful menstruation).

This train of symptoms is usually caused by more or less spinal irritation, or deformity. The spinal marrow, which is a continuation of the brain, or at least possessing similar functions, cannot be pressed on or stretched

in the slightest degree, without deranging the functions of all the nerves which are given off beneath the injured part; in the same manner as pressure on the nerves of the arm, when the limb is placed on the back of a chair, will benumb all the parts below the seat of pressure. But every one acquainted with anatomy knows, that the sensations of the nerves of the spine, below the seat of deformity or pressure, are transmitted to the organs of the abdomen, chest, and head, through the great sympathetic nerve, which is connected with the brain and spinal brain, and with all parts of the body. It is for this reason, that if there is curvature or irritation in any part of the spinal brain, the functions of the organs in the head, including those of the senses, the eyes, ears, mouth, nose;—the lungs and heart, the stomach, liver and bowels, are sooner or later affected, and their functions deranged. If the irritation or curvature occurs in the dorsal portion of the spine, the respiratory organs (lungs), and the circulatory (heart), will be principally affected, the breathing will be laborious, slow, or hurried, there will be palpitation of the heart, a sense of weight or oppression about this organ; and the lungs and heart cannot be affected without implicating the stomach, liver, spleen, intestinal tube, kidneys, genito-urinary organs, in fact, all parts of the body. When the lower dorsal or lumbar region is the seat of disease, there will be derangement of the digestive organs, stomach and bowels, flatulence, sinking at the stomach, popularly termed "sinking at the heart," confined bowels, &c., and sometimes a derangement of the genito-urinary organs, kidneys, ureters, bladder, and generative system. In these cases, the great sympathetic nerve will convey the derangement to the chest and head, and the symptoms above described may be urgent. The vision, hearing, taste, appetite, &c., in a word, all the functions, will become disordered, but those more particularly predisposed to derangement, which will vary in different constitutions. In fact, it is a received axiom in medicine, that derangement or injury in any part of the body may affect and disturb the whole, so intimately are all connected by nerves.

If we bear in mind the fact, that the spine supports the head, chest, and abdomen, and is the medium of communication between the nerves of all parts of the body and the brain, we cannot be surprised that the disorders in all parts of the body, excited by its derangements, are very numerous. It is, therefore, manifest that any cause which injures the spinal brain, or marrow, must excite the multiform disorders alluded to, and that the greatest attention should be paid to this important part of the body.

Deformities of the spine in female children are so common, that there is scarcely a family in the middle and upper classes of society in this country, which has not one or more of

its members affected with some form of this infirmity. Indeed, most of the cases of nervous, hysterical, anomalous affections, which we daily observe, are attributable to spinal disease or irritation. The causes of this disease are various, as want of nutritious aliment, pure air, every thing that debilitates the body during infancy, all acute diseases in the head, chest, abdomen, or limbs, the long continued operation of certain attitudes, tight lacing, stays, want of exercise, &c., all of which weaken the muscles of the back, and the ligaments of the spinal bones, and predispose to deformity. Of all these causes, the want of exercise, effects of attitude, tight lacing, and stays, are the most common. The evils resulting from these are graphically described by many late writers, two of whom I shall quote.

"Among the most commonly adduced causes of lateral curvature of the spine, is the long-continued influence of the same attitude. That this does operate is unquestionable, for multiplied experience has shewn it in many persons whose occupations oblige them to maintain the same posture for many hours daily. Attitude has most effect during the period of growth, but probably too much has been attributed to it; for, without the simultaneous action of other causes, it would not alone be sufficient to account for the production of spinal curvature. The attitude which a girl is obliged to assume at almost all her lessons, unquestionably tends to draw the spine to one side, and to elevate the right shoulder; which, together with want of exercise, stays and tight lacing, operates in the production of that variety of lateral curvature, which the modern system of female education has rendered so common.

"The attitude assumed in needle-work, writing, drawing, the piano, the harp, all have the same tendency to contort the spine; all these occupations are sedentary, and so many of these and other accomplishments are now demanded, that the day is hardly long enough to go through the usual lessons. Boys sit much at their studies as well as girls, but when relieved from them, their amusements are of such an active description, that the alternation of a few hours sitting is really beneficial to them; but girls, in their intervals of relaxation, are too often permitted to take no other exercise than a slow walk for an hour or so. The motions necessary for boyish games, bring into active play the muscles of the back, increase their vigour, and thus enable them to maintain the spine in its proper position, but the action of walking has but little effect on this class of muscles; the omission of those active exertions which youth of both sexes would naturally indulge in, is one main cause of such frequent instances of lateral curvature in girls. Every care is taken to check in girls that activity which is natural to the season of youth—

young ladies should not be romps—such and such exercises are boyish—delicacy of appearance is considered genteel, and we all know how successful the system is in rendering girls delicate. Even in those cases where some degree of active exercise is permitted, the poor child is eternally admonished not to assume the attitude which Nature dictates to relieve for a while the muscles of the back. Miss must not stoop, must always hold her head erect, sitting or standing; the head and chest must be upright, and straight-backed chairs, backboards, and other ingenious arts of tormenting have been invented, to prevent children from adopting the attitudes of repose dictated by Nature. Who would ever think of preventing a horse from assuming that position of repose which he almost invariably takes when standing still, by raising one of his hind legs to rest, while the body mechanically bears on the other three without much muscular exertion—in this position the spine becomes curved; and, it would be as wise to fear deformity in a horse, because he occasionally assumes this position, as in a girl to fear her being permanently round-shouldered, because she occasionally relieves herself from the irksomeness of continually maintaining the same position. Perhaps there is nothing more beautiful or more conclusive of design, than those contrivances in the structure of animals which enable them to assume positions of repose without the expenditure of muscular power. The manner in which birds roost is a familiar illustration; the weight of their body alone acts on the tendon of the flexor muscles of the toes, which thus mechanically grasp the perch without any muscular effort. The position of the horse above-mentioned, and that of the soldier when he stands at ease, are also examples of this provision of Nature."

Dr. Arnott has also made the following observations in his celebrated *Elements of Physics*:—

"Strongly as Nature has expressed herself upon the important subject of exercise among the young, tyrant fashion, with a usual perversion of common sense, has of late times in England formed a school discipline for young women of the higher classes, which wars directly with Nature's dictates; and the consequences have been such, that a stranger arriving here from China, might almost suppose it the design to make crooked and weak backs by our school discipline, as it is the design in China to make little feet by the iron shoe. The result is the more striking, because the brothers of the female victims, and who, of course, have similar constitutions, are robust, healthy, and well-formed. A *peasant girl* is allowed to obey her natural feeling, when her spirits are buoyant, and at proper times may dance, and skip, and run, until healthy exhaustion asks that repose which is equally allowed; and she thus grows up strong and

straight. But the *young lady* is receiving constant admonition to curb all propensity to such vulgar activity; and often, just as she subdues nature, she receives the praise of being *well-bred*. Her multifarious studies come powerfully in aid of the admonition, by fixing her, for many hours every day, to sedentary employment. This adoption of sedentary habits is not only hurtful, by preventing the natural extent and variety of the exercise, and thereby weakening the whole body, but is rendered particularly injurious to the back, by the manner in which the sitting is performed. It would be accounted great cruelty to make a delicate young creature stand all day, because the legs would tire; but this very cruelty is almost in constant operation against the back, as if backs could not tire as well as legs. When a girl is allowed to sit down, because she has been long standing, great care is taken that the muscles of the back, which still remain in action as she sits, shall not be at all relieved; for, from the idea that it is ungraceful to looll, she is either put upon a stool which has no back at all, or upon a very narrow chair with a perpendicular back. The stool relieves the spine more than the chair, because it allows of bending in different ways, so as to rest the different sets of muscles alternately; but the chair forces her to keep the spine quite upright, and nearly unmoved. The consequence soon is, that being first weakened generally, by sedentary habits, and the back being still farther weakened by excessive fatigue, the spine gives way in some part and bends, and the curvature becomes permanent.

"When the inclination of the back has once begun, it is very soon increased by the means used to cure it. Strong stiff stays are put on, to support the back, as it is said, but which in reality, by preventing those muscles from acting which are intended by nature as the supports, cause them to lose their strength; and when the stays are withdrawn, the body can no longer support itself. The only things forgotten are to give proper exercise in the air, and to let the child rest when she is not taking such exercise. The prejudice had at last grown up, that strong stays should be put upon children very early, to prevent the first beginning of the mischief, and that the child should always be made to sit on the straight-backed chair, or to lie on the hard plane; and, it is probable, that if these cures and preventives had been adopted as universally and strictly as many deemed them necessary, we should not have, in England, a young lady whose back would be straight or strong enough to bear the weight of her shoulders or head. It would disgust us to see the attempt made to improve the strength and shape of a young race-horse or greyhound, by binding tight splints or stays round its beautiful young body, and then tying it up in a stall; but this is the kind of absurdity and cruelty so commonly practised

in this country towards what may be well called the faultless of created things."

The pressure of tightly laced stays prevents the motion of the ribs and vertebrae, or bones of the spine (twenty-four in number), which ought to be free and frequently in motion, and renders all these parts a weight on the lower part of the spine, which bends under them, and inclines to one side, the upper often inclining to the other side; so that the back, when carefully examined, often resembles an italic S. Tight lacing benumbs, weakens, and almost paralyzes the muscles; so that these, when the pressure is removed, are incapable of supporting the spine, head, chest, and abdomen, in the erect position, and spinal distortion must result. Boys, who take active exercise, are much more seldom affected than girls, even their sisters, unless when enfeebled by some disease. Many other evils result from tight lacing, as impeded respiration, phthisis, spitting of blood, palpitation of the heart, head-aches, derangement of the digestive organs, and, consequently, of all parts of the body, according to the principles laid down in these remarks. Dr. Gregory has well observed, in his *Comparative View of the Faculties of Man with those of the Animal World*:—

"Some nations have fancied that Nature did not give a good shape to the head, and thought it would be better to mould it into the form of a sugar-loaf. The Chinese think a woman's foot much handsomer, if squeezed into a third part of its natural size. Some African nations have a like quarrel with the shape of the nose, which they think ought to be laid as flat as possible with the face. We laugh at the folly, and are shocked with the cruelty of these barbarians, but think it a very clear case, that the natural shape of a woman's chest is not so elegant as we can make it, by the confinement of stays. The common effect of this practice is obstruction in the lungs, from their not having sufficient room to play, which besides the tainting the breath, cuts off numbers of young women in the very bloom of life. But Nature has shewn her resentment of this practice in a very striking manner, by rendering above half the women of fashion deformed, in some degree or other. Deformity is peculiar to the civilized part of mankind, and is almost always the work of our own hands. The superior strength, just proportion, and agility of the savages, are entirely the effects of their hardy education, of their living mostly in the open air, and their limbs never having suffered any confinement."

It clearly follows from the preceding facts, that to confine a female infant of three, five, or seven years of age, to a restrained posture for hours together, which is generally done in schools, must weaken the muscles of the whole body; because, according to nature's laws, they ought to be in frequent motion

during the day. Delicate scrofulous boys are also seriously injured by this baneful custom.

Rachitism—Rickets.—Infants at the breast are affected with curvature of the spine, as well as deformities of the superior or inferior extremities. The disease is termed *Rickets*, or *Rachitism* (spinal disease). It is peculiar to delicate infants between the sixth month and end of the second year of their age. Its symptoms are loss of appetite, though this may be good or voracious, weakness, and disinclination to walking or motion, or to amusements; the countenance becomes pale, the skin soft, flabby, or dry and hard, the body emaciates, particularly the arms and lower limbs, the mesenteric glands and abdominal viscera enlarge and distend the abdomen, the head and joints, especially the ankles and wrists enlarge, the long bones soften, and being unable to support the weight of the body, bend, and the sternum or breast-bone projects, the ribs are flattened, and the spine becomes incurvated or crooked. The alvine motions are depraved, become pale, white, brown, green, or black; the urine deposits various sediments, the tongue is white, yellow, or brown, the whole body or economy becomes enfeebled and relaxed, the limbs refuse to perform their functions, bend in different directions under the weight of the body, the infant cannot stand or walk without difficulty, it is disposed to remain quiet, or in the recumbent position—it wishes to remain in the mother's lap or in bed—"it is off its feet."

The causes are scrofula, a peculiar diathesis or predisposition; every thing that induces debility, bad nursing, improper or bad food, leaving the infant wet, dirty, too long sitting, exposing it to a cold moist air, confining it in a close apartment, depriving it of exercise in open air, leaving it too long at the breast when the milk is bad and does not contain a due quantity of the solid part of bone (phosphate of lime). The milk is deteriorated after the twelfth or eighteenth month, is injurious to the infant, and debilitating to the mother.

The strength and infirmities of the human constitution are caused by the mismanagement of infants: the foundations of happiness or of misery in after life, are laid, though unconsciously, by nurses. I have already adduced ample attestation of this position; and if further evidence were necessary, I might cite the distressing effects of rickets, with a host of other diseases.

All the bones are softened—of the trunk, spine, and limbs. Dentition is generally retarded in rickets, because the solid part of the teeth is composed of phosphate of lime. Parents very often err in ascribing rickets and deformities of the bones to the backwardness of the teeth, when in fact, the same cause, the want of phosphate of lime in the system, induces both

diseases. During the progress of rickets, the teeth often become discoloured and decayed.

These and other debilitating causes operate most on the children of the poor, and thence we find rachitism most common among them. When the digestive organs are disordered or enfeebled, they cannot extract a sufficient nutriment (chyle) from the food; the blood will become deteriorated—unfit to nourish the different parts of the body, and these cannot perform their functions.

According as the disease advances the head enlarges, sometimes prodigiously; the deformities of the bones increase, the respiration becomes difficult on account of the deformity of the chest; the liver, spleen, and mesentery, become tuberculous and enormous in size, the lymphatic glands in every part of the body degenerate, hydrocephalus, hydrothorax, or ascites supervenes, and the infant presents a hideous appearance, and hectic fever, diarrhoea, and death, soon terminate its existence. Notwithstanding all these symptoms, the countenance is animated, the eyes bright, and the intellect precocious. These peculiarities are explained by the fact, that the brain is proportionably larger than in other children of the same age; the bones of the head are soft, and readily yield to the pressure of the cerebral mass. The organs of sense, the eye, ear, &c. are unusually developed; and the excessive growth of the brain accounts for the precocity of intelligence and of the senses.

On examining the body after death all the organs are softer than natural, on account of the want of nourishment, though some of them may be enlarged. The bones are sometimes so soft that they may be cut like muscle. The cartilages and ligaments are also softened. There is congestion or effusion in either the head, chest, or abdomen, the lungs and abdominal viscera are generally tuberculous and altered in their form, dimensions, or substance. The tissue and chemical composition of the bones are totally altered. The diseased state of the glands shows the close analogy to, or identity of, rickets with scrofula. The same plan of treatment is also employed in both diseases.

Treatment of Rachitism—Rickets.—It is an astonishing, and as yet, an inexplicable fact, that rachitis does not always prove fatal; but ceases after a continuance of a few months or years, the general health becomes good, all the deformities are removed, and the bones become perfectly straight. This fact is attested by all writers on this disease, and I have repeatedly known it verified in my own practice. Dr. Harrison has also informed me, that spinal curvature in children is easily cured, as the bones are readily reduced to their proper position.

The indications of *treatment* are to improve the appetite and general health, and to strengthen the solids by promoting digestion,

and the formation of good chyle or nutriment. These ends are to be accomplished by a most nourishing diet, gravies, jellies, soups, roasted meat, if the infant have the first teeth, and if not, gravy of beef, mutton, lamb, fowl, &c., mixed with arrow-root, sago, mashed with crumbs of good bread or mealy potatoes. Milk, rice, pearl barley, salep, semolina, with wine, are also indispensable. Ale and porter are also allowable in small quantities. Good nursing, including warm clothing, cleanliness, exercise in the open air, when the infant can walk, or it may be carried in the arms of the mother or nurse, provided it be sufficiently clothed, or in a carriage, go-cart, &c. If it be very young and unable to walk, its muscles ought to be invigorated by friction with the naked hand, a soft flesh-brush, or a piece of new flannel, on which some fine flower or hair-powder should be sprinkled to prevent irritation or excoriation of the skin. The friction should be employed over the whole surface of the body and limbs, from one to three hours, morning and evening. It is of no use unless continued for a considerable time, and then it circulates the blood, almost as much as if the young infant were able to walk.

In no case should the infant or child be placed on its feet, until it shews a disposition to assume the erect position. Let it be laid on a sofa, bed, or carpeted floor, and allowed to exert its limbs in the manner nature suggests to young infants in health.

If old enough, various amusing exercises may be devised for it; while retaining the recumbent position, pullies may be first constructed for the arms alone, and so contrived as to allow it to assume the sitting and upright positions. The regimen and diet being regulated, the next part of the treatment is to improve the digestion.

The medicines usually employed as tonics in rachitism and scrofula are quinine, calumbo, preparations of iron and iodine. These may be administered in proper doses, according to the age and constitution of the infant, in white wine, or in powders mixed with honey, treacle, currant jam, jellies, or sugar. I usually order quinine and the preparations of iron in white wine.

The vinum and tinct ferri-mur,—carbon ferri are readily taken by children in white wine. Lime water may be mixed with milk as a common drink, and soda with porter. The following powders are also highly beneficial:—

R. Hyd. c. creta, gr. vj—xij;
Pulveris rhei ℥j—3 ss;
Ferri carbon. gr. vj—xij;
Sacchari purificat. 3 ss;
Pulv. cinnam. comp. ℥ss.

In chartulas vj—xij. divide, capiatj. bis vel ter in die.

When the alvine evacuations are black, calomel should be substituted for hyd. c.

creta, and the bowels ought not to be moved more than twice a day.

The alvine dejections, or motions from the bowels, must be improved by calomel, hyd. c. creta, rhubarb, aromatic powder, and sugar.

A liniment of iodine should be applied to the abdomen when the mesenteric glands are enlarged, and the internal use of this medicine will be most advantageous. The iodine may be used as follows:—

Rx. Potassæ hydriodatis gr. j—iij;
Aque destillatæ, ℥ iij;
Dosis coch. min. bis vel ter in die;
cum saccharo.

The hydriodate of iron is also a valuable remedy. Dose—half a grain to gr. i. in solution, twice a day.

Ointment of Iodine:—

Rx. Potassæ hydriod. gr. v—x;
Adipis preparat. ℥ j;
Tinct. opii, ℥ j.

A drachm of this ointment may be rubbed on the abdomen night and morning, and a flannel bandage applied after its use.

Other remedies will be mentioned when treating of scrofula.

Mineral and vegetable alkalies, especially the phosphates, are strongly recommended by some authors; but the experience of others proves them of little value.

Cold bathing, in common or sea water, and exposure to sea air, are favourite remedies, but ought to be prescribed by medical practitioners only, as they often do much more harm than good in cases of very feeble delicate infants.

Various mechanical contrivances for supporting the spine and limbs are used with advantage, provided they do not impede the action of the muscles or prevent exercise. Many practitioners entertain the strongest prejudices against them, and content themselves with leaving deformities to Nature, when her powers are almost destroyed in weakened constitutions. But any physiologist will assist her when she requires aid. Of these means, more fully hereafter.

It now remains for me to describe the causes and treatment of spinal deformities of children to the age adolescence; and lastly, to notice a source of complicated misery in young females, dependent on spinal irritation.

Curvature of the Spine in Children from the age of Six years to the period of Womanhood.
—Delicate children from the age of six years to puberty, especially girls, are very liable to spinal irritation and deformity, more especially when confined in schools, and deprived of exercise in a pure, dry air. Their general health gradually declines, the appetite fails, and the nature of their disease is often overlooked. Some are affected with cough, copious expectoration, deranged digestion, and depraved motions from the bowels. The chest affection is sometimes so severe as to be considered consumption; and this is gene-

rally the case, when there is relaxation, or inflammation of the ligaments of the upper part of the dorsal spine.

The abdominal affections will be most urgent when the lower portion of the dorsal spine is disordered; and the pelvic organs, the genito-urinary, more particularly the uterus, causing the protean forms of hysteria, when the lumbar spine is implicated at the age of puberty. The whole or a part of these symptoms may continue for a year or two, or alternate with each other; or pain in the chest or abdomen may be experienced, simulating that of inflammation, and is too often treated as such, without any permanent relief, but absolutely with aggravation. If we observe the attitude of the child or young girl, a single glance is sufficient to convince us, that there is spinal relaxation, irritation, or disease.

On examining the spine from the nape of the neck to the sacrum by pressing, or percussing or striking it with the fingers, we invariably discover some painful part, either in the neck, back, or loins, but generally in the dorsal region, or we find one or more of the spinous processes, projecting inwards (incurvation) outwards (excurvation) or laterally (lateral curvature). In any of these conditions it is impossible for the individual to enjoy good health, and great nervousness must be present, with innumerable unpleasant or painful sensations, twitches, cramps, spasms, and pain in those organs situated near the affected part of the spine, and by sympathy in all organs in the body. Thence the frequency of excessive nervousness, indigestion, flatulence, palpitation of the heart, hysteria, hypochondriasis or dejection of spirits in girls and women, confinement of the bowels, disordered menstruation, leucorrhœa, &c., that miserable state of existence induced by the erroneous notions of society which influence female education. Thence the foundation of varied nervous disorders that embitter existence, disqualify for the proper performance of the functions subservient to reproduction, utero-gestation, parturition, lactation, and the maternal care of the offspring. The causes of lateral curvature of the spine, or growing out of the shoulder are the following; 1st, weakness of the muscles and ligaments which support the spine in the perpendicular line, by which it must bend in some direction under the weight of the head and trunk; 2d, a restrained posture, in which the individual must make use of one side or limb more than the other; and 3dly, from every position of the body which throws the spine out of its perpendicular line, and consequently out of the centre of gravity.

Delicate children or young girls whose muscular power is enfeebled, cannot retain one position, even for a few minutes, without uneasy, painful, and irksome sensations; the muscles ache, become tired, and the individual will, unless cruelly restrained, seek

relief by change of position, lean to one side, and tend to throw the spine out of the erect position. Thus, leaning too much on one side, as in writing, drawing, playing the harp, &c., produces the same evil result. Ill-made clothes will cause uncomfortable sensations, which lead the child, if a female, to elevate too frequently one shoulder more than the other, and by this motion twist the spine. The baneful practice of compelling a female child to sit up for hours on a stool, chair, or form, without the least support to the back, is the commonest cause of deformity; she obeys the command, but to relieve her aching muscles, leans to one side, or bends forwards when unobserved, and at the same time raises the head and projects the neck. Standing too much on one leg, which some children do, or are compelled to do in schools, while repeating their lessons, is another cause of deformity. The most powerful of all these causes is the use of stays or tight lacing, which most effectually weakens the muscles, and inevitably causes deformity. A girl should never wear stays before the age of fourteen or fifteen years, that is, until the muscles and bones are nearly developed. Children in the rural districts possess the finest figures, especially those of the humbler classes, who never wear stays until the age of sixteen or eighteen.

There are different degrees of spinal weakness or rotation and deformity. The muscles may be enfeebled, and the ligaments slightly relaxed, so as to admit of excurvation or projection of some part of the spine in the sitting posture. The effect of the slightest projecting or bending of the spine in any direction, will be pressure on the spinal brain or marrow, and disorder of all the nerves below the affected part, and consequently of all the organs supplied by them, and by sympathy of the whole body. This is the first degree.

When relaxation of the muscles and ligaments continues for any length of time, and curvature is the result, the pressure of the upper and lower vertebræ upon the cartilage placed between them, will cause softening, inflammation, or ulceration of it; the curvature will be considerably increased, and the pain, irritation, and disorder of all the functions augmented. The curvature may implicate three or four of the vertebræ, or sometimes the whole, occupying the spine from the head to the coccyx. This is the second degree, and when overlooked or neglected, will produce destruction of the intervertebral cartilages, and even caries of the bones, constituting the third degree, and causing extreme deformity, as the weight of the trunk above the carious bones will cause it to fall forwards or to one side, form extreme deformity, with paralysis of all parts below the seat of disease, loss of power in the lower extremities, bowels and bladder, involuntary evacuations of feces and urine, sloughing of

the integuments of the pelvis, great prostration of strength, and in general death. But such are the conservative powers of the constitution, that life may be preserved even in such formidable cases, and a union effected by the vertebræ above and below the caries. Much discrepancy of opinion exists as to the part of the spine first affected. Sir Charles Bell, and his relative, the late Mr. Shaw, maintain that lateral curvature always begins in the loins; that the curvature of the dorsal region is consecutive, and caused by the action of the muscles to restore the equilibrium of the head and chest, which was deranged by the inflection in the loins. The majority of Continental writers, and some in this country, Beale, Barlow, &c., are of opinion, that in some cases the primary curvature commences in the dorsal region. This question remains undecided. According to my experience, disease of the spine may commence in any part of the column, sometimes in the dorsal region, and sometimes in the loins. But whatever may be the differences of opinion as to the part first affected, there is one opinion entertained by a vast majority of writers, as to the treatment, which in the varieties of spinal deformity are nearly the same. The improvement of the general health by nutritious aliments, tonics, quinine, chalybeates, recumbent position, exercise of various sorts, gymnastics, traction, friction of the back, shampooing, vapour baths, &c. leeches, counter irritation, in fine, the means about to be enumerated, are most generally employed. The greater part of the day should be spent in lying on a sofa or on an inclined plane, and using such exercises as may be taken in the horizontal position, which tend to strengthen the muscles and restore the spine to its natural form: various means may also be devised to correct bad habits, as leaning to one side, raising one shoulder, &c.

The treatment of the first variety, in which there is relaxation of the muscles and ligaments, is simple and generally effectual. The recumbent position is the first step, confining the patient to a sofa or bed, which will remove the weight of the part of the body above the spinal disease, take off pressure from the spinal brain, and at once diminish or entirely prevent pain, disorder, and irritation. The spine may be compared to an architectural column which has to support a weight, and must necessarily yield, if any portion is disposed to give way. The object is to support the weight on the column and prevent it from pressing on the part which is giving way. It is easy to understand the importance of the recumbent posture. If a delicate child, whose muscles are flabby and unable to support the spine erect, and whose ligaments are relaxed, be placed in the sitting posture, and if we examine its back with the hand, we shall find several of the lower dorsal vertebræ pro-

jecting; but if we place it on its back or face, then the vertebrae cease to protrude, and the spine becomes straight. This simple fact shews the value of the recumbent posture in young children, or girls before the age of puberty. When there is little, if any pain, the patient may take exercise between times, and again resume the horizontal posture. This position should be enjoined as much as possible, without injury to the general health. It is customary in many schools, that weakly children and young ladies should lie down for an hour or two on an inclined plane made of board. This is an injurious proceeding and must be a source of torture. The pressure of the projecting part of the spine on the hard board will cause intense pain, injure the health, and aggravate the disease which it is intended to remove. Dr. Barlow of Bath, who has devoted great attention to the treatment of spinal distortions, makes the following judicious observation on this subject. He says in a letter to Mr. Beale, "I have found a great advantage in dispensing with the 'board,' as it is termed, and converting a common sofa into an inclined plane. This is readily done by any carpenter, a plane raised seven or eight inches at one end, and terminating in a point, being slipped under the cushion. This arrangement excites no observation, a consideration of some moment when the feelings are sensitive; it is always at hand, and will be used freely, when the formality and display of lying down on the board would be repulsive. From the sensible relief afforded, it becomes the favourite repose; and no time being enjoined, the parties lie down and exercise alternately, precisely as the most accurate judgment would direct." (*Observ. of Distortions of the Spine, &c.* By L. J. Beale, &c. 1834).

Mr. Stafford proposes the following contrivance. "The couch or sofa, best adapted for the patient to recline upon should be perfectly flat, and thus the whole weight of the body will be taken from off the spine; it should have a cushion upon it of an equal surface, made with horse-hair or wool, firm and elastic, yielding to the natural incurvations of the spine, and yet of such a consistence as to support the back." (*Op. Cit.*). There are so many popular works on gymnastics, that I shall not attempt to describe them. But if there is much pain in the back, which is aggravated by pressure, confinement to the recumbent position is indispensable, with application of a few leeches over the affected part. Patients affected with this, or indeed any variety of spinal affection, are delicate, feeble, and irritable, and they seldom bear much loss of blood. Rest and repeated leeching in small quantities should be tried; and if these fail, then counter irritation by means of antimonial ointment is preferable to blisters, issues, or setons. It is now generally admitted that issues and setons do

infinite mischief, by injuring the general health, which is always beset by spinal affections. So far from injuring it, we endeavour to restore it, by improving the digestive function, ~~regulating the bowels,~~ increasing the appetite, forming ~~solid~~ ^{rich} chyle, or material for ~~any~~ ^{new} blood. To accomplish these objects, we regulate the bowels with mercury, rhubarb, ~~as above directed.~~ Colocynth, and other purgatives. In ~~cases of~~ youth, or adults, improve the ~~bowels~~ ^{digestive} functions, which, ~~are of different colours, white, brown,~~ black, green, &c., and ~~are~~ ^{are} ~~consequently~~ ^{consequently} ~~effective~~ ^{effective} in odours and we next exhibit ~~various~~ ^{various} ~~other~~ ^{other} powerful tonics, with the most nutritious diet. These means usually succeed: we regulate the exercise in the open air, and in a few weeks or months, we reflect a cure without the use of any mechanical contrivances. But such contrivances are sometimes necessary, and are now so admirably constructed as to remove all objections to them. Among many inventions for ~~removing~~ ^{removing} deformities, it has been ~~proposed~~ ^{proposed} to carry a weight on the head (Shew), as milk-maids are remarkably straight. It should be recollected that such persons have seldom any deformity of the spine, but ~~in general~~ ^{in general} are well-formed, with good muscular development.

In the second and third varieties of spinal deformity, the same indications of treatment, and tonic remedies are necessary, but absolute confinement to the sofa or bed must be enjoined. The degree of irritation or inflammation is greater, and requires a more active use of leeches and counter irritation. The most scrupulous attention must be paid to ~~the~~ ^{the} improving the general health by nutritious aliment, wine, porter, animal and vegetable jellies, quinine, preparations of steel, &c. &c. Sea air and bathing are also valuable ~~adjuncts~~ ^{adjuncts}, but the last must be cautiously used.

In the third variety, caustic issues, setons, and repeated blisters, have been ~~employed~~ ^{employed} until lately, but are now very generally abandoned. In fine, the records of surgery justify the assertion, that a cure is ~~not~~ ^{not} expected in the majority of cases of the first and second variety; and that ~~in general~~ ^{in general} an anchylosis of the vertebrae often takes place in series, deformity occurs, and the individual never survives to an advanced age. There are, however, some cases, in which it is impossible to save life—in which palliation can only be effected. In some cases traction of the spine, by means of pulleys, &c., to reduce the bones to their proper position, is a successful adjunct; and this plan is much employed in this country by Dr. Harrison, Mr. Beale, and I believe, Mr. Amshury. The majority of British surgeons are very much opposed to it, and prefer gymnastics. For my own part, I cannot conceive any scientific objection to reducing subluxation of the vertebrae, as all other bones. ^{adviced there} are ^{of treat-}

ment can alone remove deformity, and re-establish health.

I find a late writer, whose work on Distortions of the Spine was awarded a prize by the Royal College of Surgeons, corroborates my opinion, and adduces the following evidence in its favour. After enumerating the various contrivances for exercising the muscles to natural curvature of the spine, he observes—

“ In addition to the means I have already recommended, and in conjunction with them, I am convinced that cautiously stretching the spine, in some cases, would be found of the greatest advantage. It stands to reason, when the spine is completely thrown out of the centre of gravity, and the curvature is great, that the exercise of the muscles and ligaments will not alone be sufficient to bring it back to its proper form: they are so contracted on one side of the curve, and so elongated and pressed upon by the vertebrae on the other, that their function is almost entirely lost. In this weakened state it is not likely they can be made to act. Stretching the spine, therefore, will effect two objects—the one, the restoring the vertebrae to their places; the other, the bringing back the muscles and ligaments to their natural situations, by which they may be enabled to recover their lost power.

“ The benefit derived from stretching the spine has been more particularly shown by Duppech, by Jalade-Lafond, and others. In proof of its beneficial effects, they have brought forward several cases, of which drawings have been made, both before and after the treatment, where this plan has been employed. In many instances the distortion has been immense, and yet if the spine had not been wholly, it had been nearly, restored to the natural form. The methods they have adopted are two,—a particular kind of machine to be used as a chair, and another as a bed. The patients sit in the former of these, being firmly fixed by a belt strapped round the body above the hips to the seat, and being gradually drawn up by pulleys and other machinery attached to the neck and beneath the ankles on each side; and in the latter they lie on the back, being fixed much in the same manner, only in the horizontal position, and by ropes and pulleys are thus extended. The best of these two machines is the best, because it has not to act against the weight of the head and trunk.”

There is also a most unjust prejudice against the use of spinal supporters, steel stays, &c. The former are now so constructed as to support the spine without pressing on the muscles more than the common stays; I have

repeatedly known great benefit and comfort produced by them. They are used by Sir Astley Cooper, Sir C. Bell, Sir B. Brodie, and all the eminent surgeons of this metropolis. Mr. Beale is also of this opinion. He says, “ Instruments to support the spine are useful as adjuncts to the treatment, so long as the period of life affords a hope of cure; and afterwards they are useful in preventing an increase of deformity, and as conducing greatly to the comfort of the wearer.” He adds, “ There are few cases of lateral curvature, which may not be cured, if properly treated before the cessation of growth. The incurable cases are those resulting from contractions within the chest, consequent on diseased lungs, and those dependent on the effects of inflammation of the cartilages and ligaments, where rigid contractions have place among those parts and the bones;—but these cases are few in comparison with the large number dependent on the other causes enumerated.” After enumerating the means of treatment, he concludes with the following remarks:—

“ In the exercises usually adopted it is essential to fix the pelvis, in order that the body should bend at the loins and the muscles of the back be called into action, otherwise the whole trunk with the pelvis, will move on the heads of the thigh-bones. This circumstance will also point out the absurdity of expecting benefit to result from exercise, while the patient is wearing a steel support, the very object of which is to fix the spine immovably on the pelvis, and thus prevent all possibility of exercise to the muscles of the back and loins. When a mechanical support is used, it should be in the intervals of exercise alone, to be taken off on every occasion when the exercises are resumed.

“ By perseverance in a system of judicious exercise, alternated with repose, lateral curvature dependent on muscular debility may be removed in most cases, and benefited in all. But these means should be employed as early as possible; the longer the parts have been allowed to retain their unnatural positions, the more difficult will be their restoration, for there is a constant tendency in distortions of the spine to increase. We have only to look at the vertebral column, to be satisfied of the certainty of an increase of any existing curvature:—In the natural condition of the spine, the base of one vertebra rests firmly on its successor; but when any part of the spine deviates to one side, the tendency of the superior vertebrae to slip is obvious, the basis of support being lost, and the chain of bones only kept together by the ligaments and muscles. From this consideration, it is obvious that children never can outgrow these distortions.”

Pigeon, or Chicken Breast.—These terms are employed when the sternum or breast bone projects, and appears sharpened. They are occasionally congenital. When infan

* A Treatise on the Injuries, the Diseases, and the Distortions of the Spine, founded on an Essay to which the Jacksonian Prize for 1826 was adjudged by the Royal College of Surgeons. By R. A. Stafford, &c. 1833.

are born with this deformity, they rarely survive beyond the second or third year; but if they live beyond this period, they are weak, emaciated, and miserable objects of disease. This distortion is generally caused by rickets, scrofula, or spinal curvature, or when any part of the lung has been obliterated by disease. (Laennec, Delpech, and others.) When this deformity arises from rickets, or scrofula, the treatment recommended for the removal of these diseases should be employed. All means which expand the chest should be recommended, especially dumb-bells. Mr. Beale advises the following exercise:—

“A mode of exercise applicable to these and many other cases, is to raise a weight attached to a cord passing over two pulleys: the other extremity of the cord should be attached to the middle of a lever, which is to be held by both hands: the patient standing, and even raising himself on his toes, to reach the handle of the cord, seizes it with both hands, alternately drawing up the weight and letting it fall: in this manner, the muscles of the arms, chest, neck, and back, are brought into action, and invigorated by exercise. A pole held by the hands, with the arms extended, and moved in various directions, is also a good kind of exercise. To these means must be added friction and pressure on the chest, before and behind, performed not once, but several times during the day, and for a quarter or half of an hour each time. Pressure on the prominent part of the thorax, applied so as to correspond with the motions of respiration, I am informed by my friend Mr. Coulson, has been extremely beneficial in many instances where he has recommended it. The great perseverance required in such cases, makes it difficult to find any person, except the mother, who will do a child justice: but a sufficient number of cases are recorded of the great benefit derived from the use of these means, when applied in early life, to afford ample encouragement to give them a fair and efficient trial.

“In the intervals of friction, and during sleep, an instrument should be worn, which will apply constant pressure on the projection: this is effected by the addition of springs and pads, similar to those of a common truss, passing from the back-plate of a shoulder-strap, or collar, and exerting counter-pressure on the seat of the malady.”

Lastly, it remains for me to notice inflammations of the joints in new-born infants—a disease only lately described, and for a knowledge of which, I am indebted to my friend, Dr. Alexander Thomson, who favoured me with a translation of a French Thesis on the subject. It is as follows:—[The paper published in Dr. Ryan's London Medical and Surgical Journal, vol. 6, p. —, by M. Terrise, on acute arthritis in new-born infants was read.]

At our next meeting, I shall describe the congenital Displacements of Soft Parts.

A NEW PRACTICAL FORMULARY.

OF HOSPITALS, OR A

Collection of Formulae of the Civil and Military Hospitals of France, Germany, Italy, Spain, Britain and Ireland, &c., containing the indication of the Doses in which simple substances, magistral and official Preparations of the Codex are administered, the use of new Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M.D., and P. VAYASSEUR, M.D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M.D. Sec. Sec. 1864

(Continued from p. 276.)

PROTO-IODURET OF MERCURY.

One of the most irritating poisons, which appears to unite the two properties of which it is composed. In very small doses it is employed in the treatment of scrofulous affections accompanied with syphilis, enlargement of the glands, &c.

INTERNALLY. Gr. $\frac{1}{4}$ — $\frac{1}{2}$, in pills.

Pills of the Proto-ioduret of Mercury. F. de M. (Proto-ioduret of mercury, gr. i; extract of juniper-berries, gr. xij; liquorice powder, q. s., for viij pills, each of which contains $\frac{1}{8}$ gr. of the proto-ioduret). From iv—viij daily, commencing with the smaller quantity, and gradually increasing it.

In syphilides.

EXTERNALLY.

Pommade of the Proto-ioduret of Mercury. F. de M. (Proto-ioduret of mercury, gr. xx; lard, $\frac{3}{4}$ iss.

Employed in venereal ulcerations.

The *Pommade d'Iode* of the H. St. L. differs from the preceding in the quantity of the proto-ioduret being increased to, gr. xxxvj, and by the addition of gutt. xv of the essence of bergamot.

The *Pommade of the Proto-ioduret of Mercury* of the H. St. L. contains, No. 1, \mathfrak{D} ij; No. 2, \mathfrak{D} ij; and No. 3, \mathfrak{D} iv, of the proto-ioduret of mercury to \mathfrak{Z} ij of lard. M. Lugol employs them in the treatment of cutaneous scrofula, complicated with syphilis.

DEUTO-IODURET OF MERCURY.

The deuto-ioduret of mercury possesses the same properties as the proto-ioduret, only it is more energetic. It is employed in the same cases; but its administration requires great prudence.

INTERNALLY. Gr. 1-16th— $\frac{1}{2}$, in solution or in pills.

Pills of the Deuto-ioduret of Mercury. F. de M. (Deuto-ioduret of mercury, gr. i; extract of juniper-berries, gr. xij; liquorice powder, q. s., for viij pills, each of which contains $\frac{1}{8}$ of a gr. of the deuto-ioduret). Two of them should be taken morning and evening, and the number gradually increased to four.

Alcoholic Solution of the Deuto-ioduret of

Mercury. R. de M. (Deuto-ioduret of mercury, gr. xx; alcohol (36°) 3 iss; 26 drops contain about $\frac{1}{2}$ of a grain of the deuto-ioduret). Gutt. x—xxx, and even more, progressively increased, in a glass of distilled water.

[Common water will speedily decompose it. This medicine is very efficacious in syphilis complicated with scrofula. T.]

Sulphuric Ether with the Deuto-ioduret of Mercury. R. de M. (The same properties as the preceding preparation). Gutt. x—xv.

EXTERNALLY.

Pommade of Deuto-ioduret of Mercury. F. de M. (Deuto-ioduret of mercury, gr. xx; lard, 3 iss).

The *Pommade d'Iode*, No. 2, of H. St. L. contains gr. xv of the deuto-ioduret of mercury to 3 ij of lard, and gutt. xx of the essential oil of bergamot.

These pommades are employed in cases of tubercles and syphilitic ulcerations; they are very active, and require a great deal of care in their administration.

CYANURET OF MERCURY.

A corrosive poison, very nearly as energetic as the deuto-chloride of this metal. It is administered with success in obstinate venereal diseases, and M. Bielt employs it with great success, externally, in cases of humid tetter, accompanied with violent itching. The greatest prudence ought to be observed in its administration.

INTERNALLY. Gr. 1-16th— $\frac{1}{2}$ daily, in solution or in pills.

Anti-syphilitic Liquor. H. de la Mat.

R. Hydrarg. cyanureti, gr. iv;

Aquæ, 3 viij.

Solve. Dosis, 3 iv—3 i; partitis vicibus.

An ounce contains $\frac{1}{2}$ gr. of the cyanuret.

Tincture of the Cyanuret of Mercury.

(Parent.)

R. Hydrarg. cyanureti, 5j;

Alcoholis, 3 x;

Extr. buxi, 3 iij;

—— aconit. nape.,

Ammon. hydrochl., 3 iij;

Olei anisi, 5j;

Aquæ, 3 xiv.

A tea-spoonful to be taken night and morning in half a glass of sugar and water, gradually increasing the dose 3 ss—j. Each ounce contains one grain of the cyanuret.

In obstinate venereal diseases.

Pills of the Cyanuret of Mercury. (Parent.)

R. Hydrarg. cyanureti, gr. vj;

Opii pulveris, gr. xij;

Miccæ panis, 3 j;

Mellis despum, q. s.

Fiat massa in pilulas xcvi dividenda, quarum sumantur una mane nocteque.

Each pill contains 1-16th of a grain of the cyanuret, and $\frac{1}{4}$ th of a grain of opium.

EXTERNALLY.

Pommade of the Cyanuret of Mercury.

H. St. L.

R. Hydrarg. cyanur. gr. xvj;

Adipis, 3 j;

Olei limonis, gutt. xv.

Misce.

Employed in certain cases of humid tetter, accompanied with inflammation and itching.

PROTO-NITRATE OF MERCURY.

In large doses it is a corrosive poison: in small ones an anti-syphilitic, generally administered in a syrup. It is used externally as a stimulant, detersive and escharotic in the treatment of tetter.

INTERNALLY.

Syrop de Bellet.

R. Hydrarg. proto-nit., 3 iij;

Aquæ acidulatæ, 3 x.

Solve, et adjice,

Syrupi simplicis, Oiss;

Ætheris nitrosi, 3 i.

Misce.

From 3 iij—iv in a mucilaginous vehicle. Each ounce contains a little more than gr. 4 $\frac{1}{2}$ of the nitrate.

Mercurial Potion. H. of Italy.

R. Syrupi Bellet.,

Aquæ destill. 3 ss.

Fiat potio, omni mane capienda.

In scrofulous affections.

EXTERNALLY.

Onguent Citrin. P. Employed in frictions in scabies.

Eau Mercurielle. P. To excite venereal ulcers.

Pommade Antidartreuse. H. of Italy.

R. Hydrarg. proto-nit. 3 i;

Unguent. cucumis, 3 ii.

Fiat unguentum.

Employed in circumscribed tetter.

Mercurial Lotion. H. St. L.

R. Hydrargyri. 3 ss;

Acid nitric. 3 j.

Solve, et adjice,

Aquæ destill. Oiss.

Fiat lotio.

In Scabies. 3 ss. should be used morning and evening. This is a very commodious preparation and is very successful.

RED OXIDE OF MERCURY.

A stimulant and escharrotic employed only externally in chronic ophthalmia attended with ulceration of the borders of the palpebræ. It is also used to destroy fungous flesh, and to excite certain venereal ulcerations. It may be absorbed and cause serious accidents if great care is not taken when employed.

[It should be most finely levigated in ointments as directed in the British Pharmacopœias. T.]

EXTERNALLY.

Pommade Ophthalmique de Regent. P. About the size of a pea, applied to the borders of the palpebræ.

The Pommade avec l'oxide de mercure, or, Pommade de Regent, of the H. de la Mat. is composed of red oxide, 3 iss; fresh butter, 3 iij, and 3 iv of white wax. It is employed in the same manner as the preceding.

Caustic Powder of Plenck. H. of Germ.

Rx. Oxyd. hydrarg. rub.,
Alum. calcin., ā ā 3 ij;
Sabinæ, 3 ss.

Misce.

Employed to repress the fungous flesh of venereal ulcerations, &c.

Mercurial Honey. (Swediaur).

Rx. Oxyd. hydrarg. rubri,
Sacchari. ā ā 3 i.

Tere et adice.

Mellis, 3 iij.

Misce.

Employed in dressing syphilitic ulcerations.

Pommade of the Red Oxide, used in Ophthalmia.

Hot. D.

Rx. Oxyd. hydrarg. rub. gr. x;
Zinci sulphatis, gr. x;
Adipis, 3 i.

Fiat unguentum.

About the size of a pea should be applied to the eye-lids. It is used in chronic ophthalmia, especially when the inflammation is increased by a scrofulous habit of body.

At the Hot. D. a Pommade is used in ophthalmia, composed of 1 part of red oxide, and 8 of an ointment of roses.

Pommade de Desault. Hot. D.

Rx. Oxyd. hydrarg. rub.,
Acetatis plumbi,
Aluminis,
Oxydi zinci, ā ā 3 ij;
Deuto-chlorueti hydr., gr. xxv;
Adipis, 3 iss.

Misce.

Employed in the same manner as the preceding.

Onguent Brun. H. Militaires.

Rx. Oxyd. hydrarg. 3 j;
Unguent. basilici, 3 i.

Fiat unguentum.

Employed in dressing atonic wounds and ulcers, as a slight stimulant.

The onguents brun of the H. des Ven. is composed of gr. iij of the red oxide to 3 i of lard.

BLACK OXIDE OF MERCURY.

This preparation is employed by German practitioners in those cases in which we (French) use the metallic preparations of mercury well triturated. It is not much used in France; its composition is subject to variation.

INTERNALLY. Gr. 4—v daily, in pills.

Pilules de Hanhemann. H. St. Ant.

Rx. Oxyd. hydrarg. rub. 3 i;
Gummi acaciæ,
Sacchari, ā ā 3 ss.

Fiant pilulæ xxx, dosis j—v quotidie.

Employed in syphilis.

EXTERNALLY. In frictions, gr. x—xx mixed with 3 i of lard, not much used.

RED SULPHURET OF MERCURY. (Cinnabar).

It has the same action as the other mercurial preparations, with the exception of the causticity of the sublimate and the oxides of mercury. It is little used at the present day, except externally, in the treatment of some chronic affections of the skin, exostoses and syphilitic ulcerations, or to combat prurigo pedicularis.

INTERNALLY. Gr. x—xx, in pills or in an electuary.

Poudre Temperante de Stahl. P. Gr. vj—xx.

Boluses of the Red Sulphuret of Mercury.

Rx. Hydrarg. sulph. rub. 3 ij;

Confectionis rosæ, q. s.

Divide in bolos iv, quorum sumat unum mane nocteque.

In obstinate cephalagia.

Analeptic Powder. H. of Germ.

Rx. Hydrarg. sulph. rub. 3 i

Sacchari purific. 3 iij.

Olei cinnamomi, m xx,

In chartulas xx divide, harum sumat unam quotidie.

Eluded as cordial, stomachic, and analeptic.

EXTERNALLY.

Pommade de Cinabre, called No. 4. H. St. L.

Rx. Hydrarg. sulph. rub. 3 iss;

Hydrochlor. ammoniac. 3 ss;

Adipis, 3 ij;

Aquæ rosæ, 3 j.

Fiat unguentum.

Employed with advantage in prurigo pedicularis.

Fumigations de Cinabre. H. St. L. and H. de la Ch.

Rx. Hydrarg. sulph. rub. 3 iss.

They are used in the same manner as those of sulphur.

Employed in the treatment of certain chronic cutaneous diseases and chronic syphilis. They have the inconvenience of causing salivation in a short time.

Mercurial Fumigations. H. des Ven.

Rx. Hydrarg. sulph. rub. 3 ss;

Olibani, 3 ij.

From 3 ss—i should be put on a plate of iron, heated till it is red, and the affected part exposed to the vapours which arise from it. They are employed in syphilitic exostoses, obstinate ulcerations, &c.

BLACK SULPHURET OF MERCURY.

It possesses the same action as the preceding preparation; it is not often used internally, except as an antelmintic. It is employed externally in the treatment of scabies.

[I have added it to the electuary of sulphur and supertartrate of potash, &c., commonly employed in this country. T.]

INTERNALLY.—As an anthelmintic, gr. v—xxi in pills, or with an electuary.

As a purgative, not much used, gr. viij—xxx.

Poudre Vermifuge Mercurielle. P. Gr. v—xx.

Purgative Electuary. H. de la Ch.

R. Hydrarg. sulph. nig.

Pulv. jalapæ, ā ā ʒ iij;

Resine jalapæ,

Scillæ, ā ā gr. lvi;

Scammonie, ʒ ss;

Syrupi rhamni, q. s.

Misce, ʒ ss—ij sumatur pro dose.

As a drastic purgative, in dropsies and Plumber's colic.

ACETATE OF MERCURY.

Not much employed at the present day. It enters into the composition of several officinal preparations.

INTERNALLY.

Pills of the Acetate of Mercury. H. of Eng.

R. Hydrarg. acetatis;

Opii,

Camphoræ, ā ā gr. xxx;

Syrupi papav, q. s.

Divide in pilulas xxx, quarum sumat affm vel duas in die.

In syphilis.

Dragées Antisyphilitiques de Keyser. (Cadet.)

R. Hydrarg. acetatis,

Gum. acaciæ, ā ā ʒ ss;

Sacchari, ʒ iij;

Pulv. althææ,

— amyli, ā ā ʒ iij;

Mucilag. acaciæ, q. s.

Fit massa, in pilulas gr. i, dividenda, quarum sumat duas mane nocteque.

The number should be gradually augmented to fifty a day.

Each pill contains 1-7th gr. of acetate of mercury.

RED-DENTED SULPHATE OF MERCURY, OR TURBITH MINERAL.

Formerly employed as an emetic and diaphoretic; at present it is scarcely ever used, except externally in the treatment of indolent tetter.

[It is sometimes used in this country in hydrophobia. T.]

EXTERNALLY.

Pommade de Turbith Mineral. H. St. L.

R. Turbith mineral, ʒ i;

Adipis, ʒ i.

Lento igne simul liquefac.

The *Pommade Antithetique* of the H. des Van is composed of ʒ i of the turbith and lardanum, ʒ ss of sulphur, and ʒ i of lard. It is employed in herpes, when there is not much inflammation.

IODINE.

In large doses it is a very energetic irritative poison; in smaller ones it exercises a

general stimulating influence, especially on the mucous membranes; it also acts upon the thyroid, mamillary glands, &c., in the latter of which it causes more or less atrophy. It is employed with great success in the treatment of bronchocele, scrofula, enlargements and indurations of the glands, the testicles, &c., of blenorrhagia, scirrhus tumours, &c. It is also used as an emmenagogue. In all cases it should be administered with the greatest care, and its use should be discontinued as soon as emaciation is perceptible.

[The discovery of iodine, as a remedy for every form of scrofula, and for a great number of other tedious and hitherto incurable diseases, is one of the most satisfactory and important. A brief account of this extraordinary remedy deserves the most attentive consideration. Iodine was discovered in 1812, by M. Courtois, a manufacturer of saltpetre in Paris, who, in procuring carbonate of soda from sea-weeds, observed that metallic vessels were corroded by the residual liquor. The newly-discovered substance was examined by Clement Desormes, and its real nature determined by Gay-Lussac, Sir H. Davy, and Dr. Wollaston—stimulant, absorbent, diuretic, emmenagogue. It was first employed by Dr. Coindet, of Geneva, as he considered that this substance was the active principle in burnt sponge. It was first recommended to the profession in this country by Sir Andrew Halliday, after his return from the continent in 1819; and in 1821, he published a paper upon it in the *London Medical Repository*, detailing its various preparations, their uses and advantages.—(See *Lond. Med. and Surg. Journ.* 1832, v. i, p. 96.) Dr. Manson, of Nottingham, commenced his trials of this remedy in March, 1821, and from that period to August, 1825, when his work on it was published, he had prescribed upwards of 180 ounces of iodine, and therefore his experience was extensive. He found it remove 116 cases of bronchocele, palsy arising from tumours or effusion in the brain, chorea, scrofula, fistula lachrymalis, nine cases of deafness from obstruction in the eustachian tube, dysphagia, white swelling, and in morbus coxarius and distorted spine considerable relief was afforded. Dr. Gairdner had published an essay on iodine in 1824, in which he decried its value, and argued that it was a dangerous remedy in some cases. He advised it in tuberculous diseases of the chest and abdomen; in phthisis and mesenteric disease; but Dr. Baron, of Gloucester, had previously recommended it in large doses in phthisis. He likewise found it useful in ascites, as also did Dr. Van der Kolk, of Amsterdam, in 1826. During the last few years, a vast number of writers had published, in the periodicals, their opinions in favour of this remedy in various diseases: but, in 1829-30, M. Lugol, of Paris, tried it on a much more extensive scale than any of

his predecessors, and reported so favourably of it, that the Academy of Sciences appointed a commission to observe his practice at the Hospital St. Louis, and these reported in the strongest terms of its inestimable value. They declared that iodine was a cure for every form of scrofula, whether glandular enlargement in the neck, axillæ, groins, or mesentery; in ulcers, however extensive; in abscesses, fistulæ, caries, venereal affections; in scrofulous habits; in cancerous ulcerations of the face and scalp; in strumous ophthalmia producing blindness; in cutaneous scrofula of the nose, upper lip, and cheeks; in large abscesses of the neck, fistulæ of the thigh, knee, &c.; white swelling of the elbow, knee, and shoulder; in ulcerations of the hip, caries of the vertebrae, lumbar abscesses, and caries of the maxillary bones. A vast number of other diseases have been relieved by iodine. Certain disorganizations of the uterus and ovary.—(Montgomery, in *Dub. Med. Trans.*, 1830; Ryan, in *Lond. Med. and Surg. Journ.*, 1832, v. i).—I have since used it successfully in scirrhusities of the uterus and breast which I deemed to be malignant; in congenital hydrocephalus, in enlargement of the liver, prostate gland, stricture of the urethra, strumous ophthalmia, opacity of the cornea, ankylosis of the ankle-joint, enlargement of the mesenteric glands, rachitism, in hypertrophy of the ventricles of the heart, in obstinate lepra vulgaris of five years' continuance, in periostitis, thickening of the tendinous sheaths of the tarsus and carpus; in ascites, hydrocephalus, hydrothorax, hydrops ovarii, and in hydrocele. Several students witnessed all the cases now enumerated, some which occurred in my practice at St. John's Hospital, the Free Hospital, and the Western Dispensary. Dr. Blake, of Nottingham, and Mr. Hughes, of Holborn, as well as myself, have cured ascites with hydriodate of potass. I have now a case of ascites with very considerable hepatic enlargement under my care at the Dispensary, which is nearly removed by this remedy, though two eminent practitioners declared it hopeless. I have also three cases of hypertrophy of the right ventricle of the heart, declared so by others as well as myself, and examined with the stethoscope by at least twenty medical students, which are astonishingly relieved by this remedy, combined in the manner hereafter mentioned. For the knowledge of the efficacy of iodine for this form of disease, I am indebted to the Formulary of the renowned Magendie. The medicine is of the greatest value in simple hypertrophy, engorgement, or schirrhosity of glandular organs, and of the tissues closely analogous to them; but no one acquainted with pathology will expect that iodine or its preparations can remove all kinds of disorganization, ossification, unless during its formation, calcareous deposits, hydatids, fungus hematodes, &c. &c. I have

never observed emaciation nor glandular atrophy caused by the ioduretted preparations, when used chemically and in graduated doses. It is important to bear in mind, that these, as well as most new medicines, are seldom genuine in the London shops, and consequently fail or do mischief. Dr. O'Shaughnessy, Mr. Periera, and Mr. Everitt, have found the hydriodate of the London shops composed of 70 parts of carbonate, and 30 of hydriodate of potass. It was used in enlargement of the spleen (M'Dowell, of Dublin, *Lond. Med. and Surg. Journ.* 1831, v. vi). Enlargement of the liver (Milligan, Elliotson, *Op. cit.*, 1832, v. ii, and *Lancet*). Scirrhus testis (A. T. Thomson and others). Hydrocele (Ricard). Ovarian dropsy (A. T. Thomson and Ryan). Enlargements of the joints after rheumatism, gout, and syphilis; thickening of tendinous sheaths, amenorrhœa, leucorrhœa, and gonorrhœa; in the first stage of phthisis (see editorial remarks); in chronic hydrocephalus; and, likewise, in stricture of the urethra, œsophagus, and lachrymal passages.

Dr. Williams, of St. Thomas's Hospital, and my colleague, Dr. Clendenning, as well as myself, have employed it in chronic periostitis with success (1835). I have also used it in stricture of the urethra, by placing a weak ointment, melted and cooled, in a portion of a metallic tube which screws on a canula, and on having been passed to the stricture, forcing out the ointment with a stilet whose extremity accurately fills the canula. The exact position and form of the stricture is first ascertained by means of the soft bougie proposed by M. Duchamp. The medicine has been administered internally in stricture, with great success, by the Germans (*Lond. Med. and Surg. Journ.*, 1834; *Dublin Med. Journ.*, 1834). I have also exhibited it in disease of the prostate gland by the mouth, vesical injection, and suppository, with great benefit. There are cases of the last named disease which are not relieved by any medicine. The ancients recommended sea-water and air in scrofula and phthisis, but they little knew that iodine and chlorine were the medicinal agents. T.]

INTERNALLY. Gr. $\frac{1}{2}$ — $\frac{j}{2}$ twice a day, in pills.

Tincture. F. & M. (Iodine $\frac{ij}{2}$ alcohol (36°) $\frac{3i}{2}$; 20 drops contain about $\frac{1}{2}$ gr. of iodine) Gutt. iv—x and even xx progressively three times a day, in half a glass of distilled water, sweetened with sugar.

[M. Magendie states, that a drop of this tincture weighs two-thirds of a grain, while a drop of the different solutions of hydriodate of potass weighs from one to two grains. This should not be forgotten when we administer these medicines in drops. The prescriber should be aware of the exact strength of the tincture or solutions which he orders; and these vary very considerably, as iodine is still excluded from the London and Edinburgh pharmacopœia,

and every physician and chemist has peculiar formulæ. T.]

Ether sulphurique iodure. F. de M. (Iodine gr. vi; æther 3 i; 30 drops contain gr. i of iodine).

Ioduretted Mineral Waters. H. St. L.

	No. 1.	No. 2.	No. 3.
R. Iodinæ,	gr. 4.	gr. 1.	gr. 1½;
Potass. } hydriod. }	gr. 1½.	gr. ij.	gr. iiss;
Aquæ destill.	gr. 3 viij.	3 viij.	3 viij;

Employed by M. Lugol in the treatment of scrofula.

At first 3 vj, then 3 viij of the water, No. 1, daily, in two or three doses. After the first fifteen days, 3 viij of No. 2 is given daily; and in the fourth, fifteen, 3 viij. of No. 3. These liquids should be sweetened at the moment of administration.

Ioduretted Solution. (Lugol).

R. Iodinæ, 3 i;
Potass. hydriod., 3 ij;
Aquæ destill., 3 viij.

Solve.

Six drops of this solution are given twice a day in half a glass of water, sweetened with sugar. Each week the dose should be increased two drops until it has reached xxx or xxxvi drops.

[If the sugar is added to the mixture, a decomposition is effected. T.]

Pills of Iodine. H. of Italy.

R. Iodinæ, gr. i;
Pulv. glycyrrh. 3 j;
Succi sambuci q. s.

Divide in pilulas viij, ex quibus sumantur ij. viij quotidie.

As Emmenagogues.

[In several cases of ovarian, uterine, and other diseases of women, treated with the ioduretted preparations, menorrhagia has been produced. According to M. Lugol and others, the most objectionable mode of using pure iodine is in pills. T.]

EXTERNALLY.

Ioduretted Solutions of Iodine for External Use. H. St. L.

	No. 1.	No. 2.	No. 3.
R. Iodinæ,	gr. ij.	gr. iij.	gr. iv;
Potass. } hydriod. }	gr. iv.	gr. vj.	gr. viij;
Aq. destill.,	Oj.	Oj.	Oj.

Employed in lotions, collyria, and fomentations in scrofulous affections, and injections in fistulous passages, the nasal fossæ, &c.

Rubefacient Solution of Iodine. H. St. L.

R. Iodinæ, 3 iv;
Pot. hydriod., 3 i;
Aq. destill., 3 vj.

Fiat solutio.

Employed to stimulate scrofulous ulcers, &c.

It is also employed in baths, added to a sufficient quantity of tepid water, until this becomes yellow.

Ioduretted Cataplasm. H. St. L.

R. Cataplasm. lini, q. v.;
Solutionis iodine rubefacient.,
q. s.

Misce.

This cataplasm is applied very hot to glandular swellings, chronic glandular swellings, &c.

Caustic Iodine. H. St. L.

R. Iodinæ,
Potass. hydriodat. aa 3 i;
Aquæ destill. 3 ij.

Solve.

This preparation is used when the rubefacient solution fails to excite scrofulous ulcerations, and to apply to cicatrices, &c.

Ioduretted Baths. H. St. L.

	No. 1.	No. 2.	No. 3.	No. 4.
R. Iodinæ,	3 ij.	3 iiss.	3 iij.	3 iv;
Potass. } hydriod. }	3 iv.	3 v.	3 vj.	3 viij;
Aq. distil.	3 vj.	3 vj.	3 vj.	3 vj.

Solve.

This solution is added to a bath, prepared in a wooden vessel.

[At the infirmary for scrofula at Margate, the greatest benefit is produced by warm ioduretted fomentations. The worst forms of scrofula are cured at this institution. T.]

In the ioduretted baths for children, the drachms of the iodine and the hydriodate of potass are changed for scruples of the same ingredients. They are employed with success in scrofula.

Ioduretted Pomades. H. St. L.

	No. 1.	No. 2.	No. 3.	No. 4.
R. Iodinæ, gr. xij,	gr. xvij,	gr. xxi,	3 i;	
Potass. } hydriod. }	3 iv,	3 ij.	3 iiss,	3 iiss;
Adip. } recent. }	3 ij,	3 ij,	3 ij,	3 ij.

Misce.

Used to dress scrofulous ulcers, and in frictions, to swellings of the same nature.

Pomade of Iodine. H. of Italy.

R. Iodinæ, 3 ss;
Adipia, 3 jss.

Fiat unguentum.

Used in frictions upon indolent tumours, &c.

HYDRIODATE OF POTASS.

It possesses the same properties as iodine, except that it is not quite so active. It is used in combination with that medicine in the treatment of bronchocele, scrofula, certain cases of cancer, scorbutic swellings of the gums, hypertrophy of the heart, &c.

INTERNALLY.

Solution of the Hydriodate of Potass. F. de M. (Hydriodate of potass, 3 ss; distilled water, 3 j; a drachm of the solution contains gr. 4½ of the hydriodate). Gutt. xx—3 ss, and even 3 i daily, the dose being gradually increased.

Solution of the Hydriodate of Potass with Iodine. (Coindet).

Rx. Potassæ hydriodat. ʒss;
Aque destillat. ʒi.

Solve, et adde,
Iodinæ, gr. x.

Misce.

Guttæ v—xv, sumantur quotidie ex semicyatho aque cum saccharo.

Atrophic Solution. (Magendie.)

Rx. Potass. hydriod. ʒiv;
Aq. lactucæ sativ. ʒ viij;
— menthæ, ʒij;
Syrup. althææ, ʒi.

Fiat mistura, cujus sumat cochleare magnum mane, nocteque.

The dose may be doubled, if gradually increased.

Employed in hypertrophy of the heart.

[M. Magendie has repeatedly employed this and the succeeding mixture in hypertrophy of the ventricles of the heart with great success. In most cases the disease began to disappear within a month. I have now four cases under treatment, which are yielding to this remedy. T.]

Atrophic Solution with the Tincture of Digitalis. (Magendie).

Rx. Potass. Hydriodat. ʒiv;
Tinct. digitalis, ʒi—ʒij;
Aq. lactucæ sativ. ʒ viij;
— florum aurant. ʒij;
Syrup. althææ, ʒss.

Fiat mistura de qua capiat cochleare magnum mane nocteque.

Employed in the same cases as the preceding, accompanied with palpitations.

[I am in the habit of prescribing the following mixture, at the institutions which I attend, in similar cases, with the most decided success.

Rx. Potassæ hydriodatis, ʒj—iv;
Aque menth. pip. ʒ viij;
Tincturæ digitalis, ʒi—ss;
Liquoris colchici, m xv—xx;
Acidi hydrocyanici, m vi—viij;
Syrupi simplicis, ʒj.

Dosis cochl. med. vel amplum bis vel ter quotidie. T.]

Ioduretted Potion. (Defermon).

Rx. Acid. prussici, gutt. x—xij;
Solut. potass. hydriodat. gutt. xv;
Aq. lactucæ, sativ. ʒiv;
Syrup. althææ, ʒi.

Fiat potio cujus capiat cochleare minimum singula hora.

Employed with advantage in certain pulmonary affections.

[He sometimes replaces the hydrocyanic acid and syrup by an ounce of the cyanic syrup of Magendie. I have employed the former mixture, and also the atrophic solution, with liquor colchici, &c., with apparent advantage in the first stage of tubercular phthisis. T.]

Pills of the Hydriodate of Potass. (Pierquin).

Rx. Potass. hydriodat. ʒijss;
Aq. destillat. ʒij;
Micæ panis, q. s.

Divide in pilulas ei de quibus sumat quatuor mane nocteque.

In hydrocele, white swellings, tumours, &c.

Each pill contains a little less than ʒi 5-6ths of the hydriodate.

EXTERNALLY.

Pommade of the Hydriodate of Potass. (Magendie).

Rx. Potass. hydriodat. ʒss;
Adipis, ʒss.

Fiat unguent.

Employed in frictions, half a drachm at a time, and, at the end of eight days, a drachm morning and evening, in hydrocele, scrofulous tumours, and certain enlargements of the testicles.

[I frequently use ʒss to ʒss in similar cases, over the sculp in congenital or chronic hydrocephalus, in enlargement of the liver, spleen, ovary, uterus, testis, in hydrocele, lepra, and other obstinate cutaneous diseases. When the skin is reddened, I persist until it has assumed its natural colour, and add ʒss of liquor opii, or gr. i—j of morphia to the ointment. T.]

Pommade of the Hydriodate of Potass with Iodine. (Magendie)

Rx. Potass. hydriodat. ʒss;
Iodinæ, gr. x—xx;
Adipis, ʒss.

Misce.

A scruple should be used in frictions in the same cases as the preceding.

IODURET OF LEAD.

It possesses the same properties as iodine, but is much more energetic in its action. It is used in the same cases as that medicine.

[The ioduret of lead is considered by far the most valuable of the metallic compounds of iodine. It does not cause cutaneous inflammation, like the preparations of iodine and hydriodate of potass, and succeeds when all these have failed. It was discovered by MM. Cattereau and Verdet de Lisle.

The dose is from a quarter to half a grain; and the ointment is composed of ʒj to ʒij of lard. This medicine is prepared by adding a solution of 100 parts of the hydriodate of potass to a solution of 750 parts of the acetate of lead. One hundred parts of this compound consists of 54.9 iodine, 45.1 lead (M. Henry (fils), *Journal de Pharmacie*, Mai, 1831). It was discovered by M. Polydore Boullay in 1827, and lately brought under the notice of the profession in Paris, by M. Caventon. T.]

INTERNALLY. Gr. ʒ—j in pills, which should be gradually increased to gr. xij and gradually to gr. xxx—xxx.

Pills of Ioduret of Lead. (Cottareau).R_x. Plumbi ioduret, 3 ss;

Confect. rose, q. s.

In pilulas cxliv divide, ex bis sumatur una mane nocteque, et augeatur dosis gradatim ad xij quotidie.

In scrofula, tabes mesenterica, scirrhus tumours, &c.

EXTERNALLY.

Pommade of the Ioduret of Lead.R_x. Plumbi ioduret, 3 i;

Adipis, 3 j;

Olei limonis, q. s.

Fiat unguentum.

Employed in frictions and to dress scrofulous ulcerations.

[I have found this ointment more efficacious than any other in scrofula of the glands of the neck in children. In one case, a female child aged nine years, had a chain of enlarged glands from one ear to the other, and on each side of the neck to the clavicle. The number affected was 22, and these varied from the size of a hazel nut to that of a pullet's egg. A cure was effected by the ointment under notice. A boy aged seven years had a tumour of great size extending from the right mastoid process to the clavicle. He was cured by this remedy. I also apply in solution ʒi—3 i to 3 vj of distilled water, as a solution for scrofulous and cancerous ulcerations, and morphia or liq. opii. sed. T.]

IODURET OF ZINC.

The ioduret of zinc possesses nearly the same properties as the hydriodate of potass. It is only employed externally in frictions on scrofulous tumours.

Ointment of the Ioduret of Zinc. H. of Eng.R_x. Ioduretum zinc., 3 i;

Adipis preparata, 3 i.

Fiat unguentum cujus, 3 i utatur, bis in die.

In frictions.

IODURET OF ARSENIC.

It possesses the properties of its two compounds. It is only used externally in tubercular herpes.

Pommade of the Ioduret of Arsenic. H. St. L.R_x. Ioduret arsenic, gr. iij;

Adipis prep. 3 j.

Fiat unguentum.

IODURET OF BARIUM.

Its properties are analogous to those of the preceding substances. Employed only externally in scrofulous swellings.

Pommade of the Ioduret of Barium. H. St. L.R_x. Ioduret bari, gr. iv;

Adipis prepar. 3 i.

Fiat unguentum.

In frictions, in slight scrofulous engorgements.

IODURET OF LIME.

[Is not employed medicinally. T.]

IODURET OF SULPHUR.

It possesses properties similar to the preceding substances. It is only used externally in certain cutaneous forms of scrofula and tubercles of the skin.

Pommade of the Ioduret of Sulphur. H. St. L.R_x. Ioduret sulphuris, gr. xxij;

Adipis prepar. 3 vj.

Fiat unguentum.

Another formula contains 8 parts of the ioduret to 144 of lard.

HYDRIODURATE OF IRON.

Stimulant, tonic, possessing the properties of iodine and iron. Recently lauded by M. Pierquin in the treatment of amenorrhœa and leucorrhœa. M. Audral has employed it in phthisis to modify the qualities of the blood, whose hematosiis is imperfect in this disease.

[It has been very strongly recommended by Dr. A. T. Thomson. (See Iron.) T.]

INTERNALLY. Gr. ij—iv a-day, in pills, rapidly increased to gr. xv—xx.

[Dr. Thomson advises it in draughts. T.]

Pastille (Lozenges of Hydriod. of Iron).

(Pierquin.)

R_x. Ferri hydriod. 3 j;

Croci pulv. 3 iv;

Sacchari, 3 viij.

Divide in pastillos cxvi. Dosis viij—x quotidie.

In amenorrhœa and leucorrhœa.

Chocolate of Hydriod. of Iron. Gr. cxv—Oj. Half a cupful a-day. In some cases.

Wine. 3 iv—Oj of Bordeaux. 3 ss morning and evening.

EXTERNALLY. 3 iv. Oj of water, in enemata, injections, lotions, several times a-day.

Baths. 3 ij to any quantity of water.

Ointment. 3 iss—3 j—3 j. In frictions. Night and morning.

(To be continued).

Revised.

Outlines of Botany, Including a General History of the Vegetable Kingdom, &c. By Gilbert T. Burnett, F. L. S., Professor of Botany in King's College. London, &c. &c. 2 vols. 8vo. 1885.

This admirable work is now complete. It has been so frequently and favourably noticed while in progress, as to render eulogium almost superfluous. This is by far the most elaborate and instructive work on the principles of botany that has yet appeared in the English language, and its distinguishing excellence is the able view which it contains of the relation of botany to the other natural sciences.

Considered apart from these, systematic botany is, like mere conchology, an elegant and pleasing pursuit for those who have no graver occupation, but still scarcely worthy to be called a science; considered, however, in its relations to physiology, medicine, geology, and other important branches of natural knowledge, botany expands into a grand science, equally delightful in the objects with which it is conversant, and useful in the sources of information which it opens.

We strongly recommend Professor Burnett's work as a faithful guide to this magnificent study, which is too often neglected altogether, and still oftener misapprehended as to its real objects and extent.

—o—

A Practical Compendium of the Diseases of the Skin, with Cases; including a particular Consideration of the more frequent and intractable form of these affections. By Jonathan Green, MD. M.R. C.S., late Surgeon in the Royal Navy. 8vo. pp. 371. London: Whittaker & Co. 1835.

SEVERAL treatises on cutaneous diseases have issued from the press during the present century; but this branch of medicine is as yet almost totally neglected in our schools. There is one radical defect in almost all the works on diseases of the skin—with the exceptions of Alibert's and Plumbe's—that they have not given the anatomy, physiology, and pathology of the skin, or, to speak correctly, of the integumentary system. The authors of the works referred to, take for granted that the great body of medical practitioners are acquainted with the general anatomy and physiology of the tegumentary apparatus, which is by no means the fact. The Baron Alibert is the only author on dermapathology, who has prefixed a proper account of the anatomy and physiology of the tegumentary system, to the descriptions of its diseases and their treatment; and even his account is very imperfect.

Though many of the diseases of the skin were described by the ancient Greek, Arabian, and Latin writers, there was no attempt made to classify them until the seventeenth century. The first attempt at classification was made by Hoffenreffer in his work published at Tubingen, 1630, and

was very unscientific. He included wounds, ulcers, and fistulae, among cutaneous diseases. Mercurialis published at this period, and divided cutaneous diseases into two classes—those that affected the head, and those that affected the body. This classification was adopted by Turner in 1736, who proposed an additional arrangement according as the diseases were produced by internal or external causes. Lorry was the next writer, in 1777, and he adopted the proposals of his predecessors, while his successor Retz, divided all cutaneous diseases into acute and chronic, in 1790. The next writer was Plenck, who classified the diseases under notice, according to their external characters and made the first step towards a pathological arrangement, 1796. He divided diseases of the skin into fourteen classes:—1, maculae; 2, pustulae; 3, vesiculae; 4, bullae; 5, papulae; 6, crustae; 7, squamae; 8, callositates; 9, excrescentae; 10, ulcera; 11, vulnera; 12, insecta cutanea; 13, morbi unguium; and 14, morbi capillorum. This was the foundation of Willan's classification:—1, papulae; 2, squamae; 3, tuberculae; 4, exanthemata; 5, bullae; 6, vesiculae; 7, pustulae; and 8, maculae. Bateman also adopted this arrangement, to which Baron Alibert, M. Rayer, Mr. Plumbe, Dr. Paget, and our author, oppose well founded objections.

The Baron Alibert attempted to classify diseases of the skin according to the natural order, and he divided them into twelve classes or groups:—1, eczematous dermatoses; 2, exanthematous dermatoses; 3, teigneous dermatoses; 4, dartrous dermatoses; 5, cancerous dermatoses; 6, leprous dermatoses; 7, verolous dermatoses; 8, strumous dermatoses; 9, scabious; 10, haematous dermatoses; 11, dyschromatous; and 12, herpetic dermatoses (1806 and 1832).

Mr. Plumbe and Mr. Dendy (in 1824-27) followed and arranged cutaneous affections according as they were symptomatic of derangement of the alimentary canal, or independent of this cause, or consequent to specific infection; they have, however, adopted the arrangement of Willan, as also have M. Rayer, MM. Cazenau and Schledel, and Dr. Green, with certain modifications in 1833-35. Dr. Paget in a prize essay, published in the Edinburgh Medical and Surgical Journal, 1833, prefers the natural arrange-

ment of Baron Alibert to that of Willan, but properly admits that both are imperfect. It appears, to us, that the classification of M. Rayer is vastly superior to either, because it is based on pathological anatomy and physiology. His classification is the following:—

"I. *Diseases of the Skin*.—1. Inflammations of the skin, including the eight classes of Willan and Bateman, with others; furunculosis, linear (fissure), gangrenous and multiform (syphilitic eruptions); 2, cutaneous and subcutaneous congestions and hæmorrhages; including, cyanosis, vibices, petechiæ, purpura hæmorrhagica, ecchymosis, and dermatorrhagia; 3, neuroses of the skin, exaltation, diminution, abolition of sensibility of the skin, without appreciable alteration in the texture of this membrane; 4, alterations in the colour of the skin—*a*, decoloration, partial or general leucopathia, chlorosis; *b*, accidental colorations; ephelis, lentigo, chloasma, meladermia, icterus, nævus maculosus, and bronze tint produced by nitrate of silver; 5, morbid secretions; ephidrosis, acne, follicular tumours; 6, defects of conformation and texture, hypertrophies, and accidental productions; distention of the skin, cicatrices, vegetations, nævus hæmatodes, subcutaneous vascular tumours, warts, pearly granulations, corns, ichthyosis, horny appendages.

"II. *Alterations of the Appendages of the Skin*.—1. Alterations of the nails and of the skin that produces them; onyxia, increased growth of the nails; spots, change of colour, fall, desquamation, reproduction, &c. of the nails; 2, alterations of the hair and of the follicles that produce it. Inflammation of the bulbs of the hair, accidental colorations canities; alopecia (baldness); matting of the hair, plica, and accidental pilous tissue.

"III. *Foreign Bodies observed on the Surface, or on the Substance of the Skin*.—*a*, Inanimate: dirt, dirt of the scalp of new-born infants, inorganic matters and artificial colorations. *b*, animate: pediculus humanus corporis; *p. capitis*; *p. pubis*; pulex irritans; *p. penetrans*; acarus scabiei; æstrus gortius.

"IV. *Diseases primarily foreign to the Skin, but which may alter it*.—Elephantiasis of the Arabs."

We shall now introduce Dr. Green's classification:—

"I. Inflammations of the skin nearly similar in arrangement to the preceding; 2, diseases which appear with the elementary characters of almost all the above orders, syphilis; 3, diseases which are severally types of new and additional orders, pellagra, purpura, elephantiasis Arabica, cheiloides; 4, original or accidental unusual states of the skin not referable to inflammation, achora; leucopathia (Albinismus);

vitiligo, dischroa-maculæ, lentigo, ephelis, chloasma, and nævus; 5, diseases of the appendages of the skin; more properly of the parts that secrete or support these; epidermes, ichthyosis. Ungues, onychia pili. plica.

We leave our readers to form their own opinions on the comparative merits of this and the former classifications. We shall have an early opportunity of commenting upon them, and shall then express our opinion. And now for the work before us.

Dr. Green prefixes twenty-four pages on the etiology, nosology, pathology, and treatment of cutaneous diseases to his individual descriptions; and shews both judgment and great experience in his remarks. He has long enjoyed a great opportunity of observing cutaneous diseases, as the proprietor of the best establishment in this metropolis for the various kinds of baths. He adduces many cases which defied all remedies except sulphurous and vapour baths; and he intersperses several clinical reports when describing the different diseases. He calls upon the profession to give a fair trial to the use of baths in the treatment of cutaneous diseases; and he might have adduced a body of evidence in their favour, from the Hopital St. Louis and other continental institutions, which would not fail to convince any practitioner of their efficacy. He might have recorded that baths of different kinds were ordered at the hospital mentioned, for internal patients, in 1838, to the number of 18,538, and for external, 82,604; and in 1822, the number for both classes of patients was 127,752—the average number of patients being about 6,000.

It is a singular fact, that baths are very partially used in this country, unless in private establishments such as Dr. Green's and those of Sir Arthur Clarke, and Dr. Wallace, in Dublin. We by no means consider them infallible remedies, but experience has convinced us they ought to be much more frequently employed than they are in this country.

In conclusion, we must observe that this work is not a complete treatise on cutaneous diseases. It is an excellent compendium, evincing great experience and success on the part of the author.

**DEFECTS OF THE LONDON HOSPITAL
SYSTEM.**

THOUGH it is not long since we alluded to the defects of our metropolitan hospitals, the subject is one of such importance to the community, and to medical science, that we shall dilate somewhat further upon it. The improved organization of the profession which will doubtless ere long take place, will contribute much to the convenience and respectability of the existing generation of practitioners; but unless some provision be made for extending the means of professional instruction, and the opportunities of scientific research, there is no chance of our being able to keep pace with the progress of medicine in other countries. With minds admirably framed for grave pursuits, by a natural solidity of judgment, and power of application, and with materials which *ought* to be at least equal to those found elsewhere, we shall continue to be, as we now are, outstripped in the pursuit of scientific medicine by our brethren of France, Germany, and even Italy. We do not mean to say that British practitioners are inferior in their treatment of disease; on the contrary, we believe that they have, in this respect, greatly the advantage of those of any other nation; but we do say with regret, that more is at present doing towards enlarging the boundaries of the science on the continent than in England. And who are the men thus profitably employed abroad? Chiefly the medical officers of public charities. And why do not our hospital physicians and surgeons follow their example? Because they are lazy, says one; because they are ignorant, says another; because they are unconscientious, says a third. No one of these allegations is true; they are neither lazy nor ignorant, and they have as much conscience

as other men. They do not fulfil their functions properly, simply because they cannot. In a country like this, where money is the soul of every thing, and an absurd spirit of ostentation pervades the gravest, as well as the most frivolous portion of society, the attention of the practitioner is absorbed by the ways and means of keeping up a wasteful expenditure, which, however opposed to his inclination, he cannot avoid. While the French physician is pursuing science, the English physician is hunting fees; while the former is engaged in establishing a theory, the latter is intent on setting up a vehicle!

In such a state of things, how can it be expected that the English hospital functionary shall devote his time and talents to studies, which however beneficial to the world at large, leave him without the means of living? Were he to do so, he would not merely be a man of science, but a martyr to science.

If the hospital physician or surgeon in this country is to produce results commensurate with his opportunities, he must be allowed an ample salary, which will relieve him from the distractions of private practice, which will enable him to lead a calm and philosophical life, and addict himself with undivided zeal and attention to the important duties of his office. Then, and not till then, may we expect to see medical students adequately instructed—medical literature enriched with great and original practical works—and British medicine raised to the high level which the individual talents and acquirements of its professors entitle it to hold.

Although we do not join in the vituperation that has been showered on our hospital functionaries, there is one remark that suggests itself with respect to them, or rather with respect to the class from which they are chosen. We hope to see the time when the selection of individuals to fill such places will be made from the profession at large, and not from two exclusive orders, the

very paucity of whose numbers renders it unlikely that the most competent persons should be found among them, to say nothing of the fact that the great body of general practitioners, who have been hitherto shut out from public medical offices, are usually men quite equal in learning and science, and much superior in practical skill, to the *pures* of either denomination, who alone have been deemed eligible. It is truly remarkable that among the regulations of almost all our medical charities, we find one or more to exclude the general practitioner. Now this is manifestly the work of the corporations—the grasping, plotting, sneaking corporations; such an idea could never have entered the heads of the directors of hospitals and dispensaries, if it had not been slyly infused by emissaries from Lincoln's Inn and Pall Mall; and when those who preside over such charities find out the real drift of the *no pharmacy* and *no midwifery* clauses in their regulations, they will be struck with astonishment and confusion at having been so woefully gulled, and made the tools of two execrable juntos to insult and injure nine-tenths of the whole medical profession?

As far then as medical officers are concerned, there are two things indispensable for the improvement of our hospital system. First, that the medical officers be allowed a very handsome salary, to induce men of character and talent to give themselves up almost entirely to the cultivation of so fine a field. Secondly, that the medical officers be chosen from the profession, not from two small and by no means distinguished parties in it.

A word in conclusion concerning patients. When a patient is once in one of our hospitals, he has, we believe, generally speaking, not much to complain of; but the difficulty of obtaining admission is a very serious grievance. A sick man has time to die and be decently interred before he can get any

relief; and this arises partly from the necessity of hunting about the town for a recommendation from a governor, and partly from the circumstance of patients being admitted only on certain days, and at certain hours. All this is just the reverse of what it ought to be; in admitting a patient into a public hospital, the only considerations should be whether his case is urgent, whether he is poor, and whether there is room for him. We have known wretched beings remain without advice, without attendance, and almost without the necessaries of life, for a whole week or more, because they could not get a letter, or because they could not reach the hospital at the right time. In England, when a poor fellow comes upon public charity, we take good care to let him feel his situation. In France, a patient goes to the hospital without any feeling of humiliation; he goes as a poor, but not on that account a degraded man, to avail himself of a civil privilege for which he is not indebted to any individual whatsoever. He is secure of a ready admission, and humane, and even courteous treatment. Not so the depressed and cringing object of English charity; he applies to the hospital with the feelings of a pauper, dreading a rough repulse from the *Cerberus* at the door, and, by a natural deduction, not over certain of civil treatment if he gets in.

All this arises from our hospitals being in effect *private* institutions; they are called public only from their magnitude—they are not *national* in their spirit.

We shall, on a future occasion, direct the attention of our readers to the necessity, and possibility, of instituting hospitals over which the government of the country shall have a direct control, and which may thus be rendered at once efficient practical schools, grand centres of medical science, and truly charitable asylums for the diseased poor.

Foreign Medicine.**Extirpation of Goitres.**

THE following operations were performed by M. Graëfe, at Berlin, in the year 1833:—

Case 1. A young man, twenty-two years of age, had a tumour the size of a goose's egg in the anterior and middle part of the neck, which occasioned extreme difficulty of deglutition and respiration. These symptoms, so little in accordance with the small size of the tumour, rendered it probable that the latter adhered closely to the anterior part of the larynx and trachea, which circumstance M. Graëfe was careful to keep in view during the operation. An incision was made through the skin, commencing a finger's breadth above the superior margin of the thyroid cartilage, and extending down the median line of the neck to the top of the sternum. The subcutaneous and sternomastoid muscles were then drawn to the right and left, which exposed the tumour, presenting a shining aspect. The surrounding parts were detached with the finger, and a bistoury, and some arteries were tied. The tumour was now found to adhere closely to the larynx and trachea, without the intervention of any cellular substance. The excision of the goitre was performed with the greatest caution by small strokes of the knife, and the portion of it which adhered to the air tube was not removed. Only eight arteries were tied during the operation. The wound was filled with lint—union by the first intention being avoided, in order that the still adherent part of the tumour might be discharged by suppuration, which accordingly took place. The lips of the wound were afterwards placed in accurate apposition, and the cure was complete at the end of six weeks.

Case 2.—A young woman, twenty-five years of age, of a delicate constitution, had been affected from her infancy with a goitre which was divided into three very distinct lobules. The immense size of the tumour precluded its entire removal at one operation; it was therefore determined to begin with the middle lobule, which was the largest, and appeared to be the nucleus of the morbid growth. The operation was conducted as in the preceding case, except that the tumour being attached to the larynx and trachea only by loose cellular tissue, there was no necessity for leaving any part of it adherent. The wound was united by adhesive straps, and was entirely cicatrized in six weeks. The lateral lobes, instead of enlarging, as there was reason to fear, diminished considerably, confirming the opinion of M. Graëfe, that the middle lobe formed the nucleus of the tumour. Perhaps, also, the inflammation consequent on the operation, and the obliteration of the vessels that were tied, contributed to the absorption of the remaining lobules.—*Gazette Médicale.*

Diabetes Mellitus.

—Josia, aged twenty-nine years, was seized in the summer of 1834 with extreme thirst, which he allayed by drinking large quantities of cold water. A few days after, he observed a great augmentation in the excretion of urine. Both these symptoms rapidly increased, accompanied with loss of strength and emaciation. When his thirst was greatest, he drank six decanters of water in the twenty-four hours, and passed a proportionally large quantity of urine. Shortly after he was admitted at La Charité, complaining of pain in the epigastrium, accompanied with vomiting, of which symptoms he was relieved by cupping in the epigastrium, and left the hospital still labouring under diabetes. In a few days an increase of the diabetic symptoms, now accompanied with cramps in the legs, and oedema of the lower extremities, induced him to enter the Hôpital St. Antoine, under M. Malet, on the 21st October, 1834, five months after the first accession of the disease. At this time he passed daily nine quarts of urine, while he never drank more than six quarts of fluid. He was free from fever, but much emaciated; had very little pain in the epigastrium, but much thirst and burning heat in the mouth; occasional, and very slight lancinating pains in the region of the left kidney; skin constantly dry. The nocturnal sweats, an aphrodisia, peculiar swelling of the gums, and affections of the alimentary canal, which some recent observations have coupled with diabetes mellitus, were entirely absent in this case; the symptoms alluded to, however, have been remarked only in cases of much longer standing than that here described. The urine was subjected to a careful analysis by M. Mialhe, chief pharmacien to the hospital. It was found to contain a smaller proportion of urea and uric acid than healthy urine—phosphates of lime and magnesia—sub-phosphate of lime—alkaline sulphates and muriates—caseous matter—a trace of fibrine, and no albumen. The residue of evaporation, treated with boiling alcohol, gave 31 grammes of saccharine matter in 500, which, divested of impurities, precisely resembled grape sugar, as observed also by Nicolas, Gueudeville, Thénard, and Dupuytren. This analysis is opposed to the opinion that the entire absence of urea in the urine is an essential feature of the disease. The case was at first treated by M. Mialhe according to the views of M. Dézelmeris, with repeated applications of leeches to the epigastrium and anus—vapour baths—and ptisan in very moderate quantity. No benefit, however, was derived but a temporary diminution of thirst, and abolition of the slight pains in the epigastrium; this treatment was therefore abandoned in favour of an azotized regimen, and the patient was allowed two pounds of fresh pork daily, with bread and wine,

six pounds of iced water, and ptisan at discretion. The baths were continued from time to time. Under this regimen all the symptoms diminished, and the urine was reduced to three quarts, with a progressive decrease of saccharine matter, and augmentation of urea. In accordance with the observations of M. Thénard, the urine presented no trace of albumen, while the urea was increasing and the saccharine matter diminishing. After a decided amelioration of the symptoms had taken place, beef was substituted for a portion of the pork, as the patient had become disgusted with so fat a diet. On the 6th of December, about thirty days from the commencement of the azotized regimen, Josia left the hospital free of all bad symptoms except the imperspirable state of the skin, which had existed during his whole life. This case, communicated by M. Fournet, being of some interest, but too long in the original to be extracted entire, is here abridged from the Archives Générales Férierien.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Rhinoplastic Operation.

March 26th. At pages 25 and 125 of our present volume, will be found a report of the case of deficient nose, in which Mr. Keate performed the rhinoplastic operation, and which, at the period of last report, appeared likely to terminate in every respect favourably. These anticipations, however, were not altogether verified, partial success having only attended it. The flap of skin, which, our readers will recollect, was taken from the forehead, had united partially all round, but the union between it and the surrounding skin has only been permanent at its superior and inferior borders; the adhesions on each side, and more particularly on the right side, where it encroached almost on the conjunctiva, having given way. This unfavourable result appears partly to be owing to the two following causes:—

First. The flap being somewhat broader than requisite; and secondly, to the difference in the texture of the opposed surfaces of the skin on the right side; the one consisting of the skin taken from the forehead, and the other of the delicate dermis of the palpebræ and their internal commissure. The man was brought into the theatre to-day, to have these defects partially remedied. Mr. Keate restricted himself, on this occasion, to paring the edges of the left side of the flap and the corresponding margin of skin, and bringing them together with five or six stitches of interrupted suture. In refreshing the edges of the flap, the circulation in it was found to be quite re-established, and there is no doubt as to adhesion taking

place on this side. Mr. Keate, however, candidly confessed that he felt quite at a loss as to what could be devised for the opposite side, where the difficulties which we have alluded to exist, and said he should be most happy to receive the suggestions of any of the gentlemen upon the subject.

WESTMINSTER HOSPITAL.

Subcutaneous erectile Tumours—Operation, Consecutive Erysipelas.

FREDERICK CONKWEILL, aged 8 years, was born with several small tumours on the right arm, hand, and fingers. During the past few months, these have considerably increased in size, and have excited the apprehensions of his friends, who have brought him to the hospital to see whether they could be removed by an operation. Mr. W. B. Lynn, to whose lot the patient fell, consulted with the other surgeons respecting him. Sir Anthony Carlisle was of opinion that they were fatty tumours, and rather discouraged any operation being performed. Mr. Guthrie and Mr. White, however, agreed with Mr. Lynn in considering them as nævi, or, as Mr. Lynn denominated them, placenta tumours, from their tissue consisting, in his opinion, of a congeries or plexus of vessels. It was agreed that the largest of the tumours should be removed first, before anything was done with the more numerous smaller ones. The large tumour, which is to be removed, is situated on the ulnar side of the lower half of the fore arm, and is about the size of a hen's egg, having an elongated prolongation of its substance inferiorly extending nearly to the wrist. Another, on the back of the hand, is only about a fourth of the size, and three or four of still smaller dimensions exists on the back of the ring and little fingers. In one respect, these tumours do not agree in character with ordinary subcutaneous erectile tumours, which is, that they do not exhibit any vascular appearance through their integument. Singularly enough, however, the skin covering the tumour on the back of the hand is discoloured, apparently from the development, to a trifling extent, of the erectile tissue in the substance of the corium, in this situation.

February 7th. Mr. Lynn proceeded, to-day, to remove the large tumour from the arm; which he did by making two semi-lunar incisions, so as to leave an elliptical piece of skin, of rather considerable size, over the tumour. A little blood was lost from several small vessels, which were divided in separating it from the subjacent fascia, a considerable surface of which was exposed. The wound was dressed in the ordinary manner, with adhesive straps, &c., and the boy was removed to a bed in Percy ward.

Upon making a section of the tumour after its removal, it was seen to be evidently consisting of accidental erectile tissue, with which, however, a good deal of adipose tissue was intermixed, and which was so empty of blood, that it might be said to be in a state of comparative anæmia, which would appear to support an idea expressed by Mr. Guthrie, that "the tumours were undergoing a spontaneous cure."

14th. A few days after the operation was performed, a rather excessive degree of inflammation set in, in the wound, which has suppurated: it however appears to be now lessened, and the wound to be filling up with granulations.

17th. Erysipelatous inflammation has spread up the arm, in the course of the absorbents, and is apparently venting its force in the formation of matter in the axilla. Rather severe constitutional disturbance has been excited; pulse is 120, and feeble; skin hot; tongue covered with a whitish fur; countenance anxious, depressed, and flushed. He is taking anti-febrile remedies.

21st. The general symptoms are much relieved since last report; there is free sup-puration from the wound in the arm, which looks much less irritable: the tumefaction and redness in the axilla still remain, but no distinct fluctuation can be distinguished.

23rd. The wound in the arm is now rapidly filling up with granulations, which have a healthy character. The tumefaction, &c., in the axilla still continue; almost all the symptoms of irritative fever have disappeared, and the boy's general health is fast improving.

26th. Considerably better; the inflammation in the axilla is subsiding, without the formation of any abscess; the wound in the fore-arm, occasioned by the removal of the tumour, is rapidly healing, and the boy has now nearly recovered his usual health.

27th. Same as last report. It is now observed that the tumours on the back of the hand and fingers have considerably diminished in size, whilst he has been the subject of the illness consequent to the removal of the large tumour, and its necessary concomitants of low diet, &c. Most probably, however, this arises merely from the absorption of the fat which was found to constitute a considerable portion of the elements of the large tumour which was removed, and that the proper erectile tissue itself remains unaffected.

March 4th. Better, the wound in the arm is about cicatrizing; the tumours on the hand are, I think, hardly so small as at last report.

14th. He is rapidly getting well, the tumour in the axilla has now disappeared without matter forming; the wound in the fore-arm has nearly cicatrized, and his general health is quite established. Mr. Lynn has directed straps of adhesive plaster to be bound tightly around the fingers, with the view of exciting, by means of pressure, the absorption of the tissue of which tumours there situate are composed; and which, as before stated, are somewhat less than before the operation.

21st. The absorption of the tumours does not appear to advance, but, on the contrary, they rather appear to enlarge as the boy's health improves, and in addition, a fresh tumour has begun to form on the back of the hand, close by one of the others, and in the angle between the ring and the little finger, which occasions the patient a little pain.

LECTURES

ON

MEDICAL JURISPRUDENCE,

DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,

At the University of London; Session 1834-35.

LECTURE XXIV.

GENTLEMEN—The division of our subject upon which we are now about to enter is one of the utmost importance, embracing questions, in which medical testimony is required, connected with personal safety and life.

Happily in this, and many other countries, no death can happen, which is not the result of obvious ill health or disease, without an investigation of the circumstances which have led to it. In some instances the facts are so clear that no medical opinion can be required; but, in many cases, this cannot be dispensed with; and, not unfrequently, on the medical evidence alone depends the life of an individual: the responsibility, therefore, is too great to be undertaken without an accurate examination into every circumstance which can have affected the issue.

It would be impossible, in the period of time allotted for this course of lectures, to inquire into every cause of death demanding a legal investigation: those which commonly occur are, therefore, selected; and, from the mode in which decisions are arrived at in these, some idea may be formed of what may be requisite in others. The first subject under this head in your syllabus refers to *injuries* and *mutilations*.

Although I have used the term *injuries*, yet the legal phrase is *wounds*, under which are comprehended not only *incised* and *punctured* wounds, and *gun-shot* wounds, but, also, *bruises* and *lacerations*. In the ordinary phraseology of society, wounds are *slight*, *dangerous*, or *mortal*; but the event of any wound, except those which may be classed under the last head, *mortal*, depends so much on *position* and *circumstances*, that it is impossible to adhere to such an arrangement. No one would hesitate to regard an abrasion of the skin of the leg as a slight wound, yet

in certain states of the habit this may prove mortal—as was illustrated in the case of the learned Jacob Bryant, who bruised his shin against a chair, in the act of reaching a book from a shelf, and died of mortification of the limb, the sequel of this trifling injury. On the other hand, wounds which are apparently of the most formidable description may, nevertheless, terminate favourably, contrary to all expectation. In 1712, a case was published by Mr. William Maiden, of complete recovery after the shaft of a chaise had been forced through the thorax; the late Dr. Monro, in his anatomical lectures, used to mention an instance of recovery after a red hot poker had passed through the lungs; and Dr. Male, mentioning the possibility of persons recovering whose brains have been wounded to a considerable depth, tells a story of a pauper in Paris, who used to receive charity in a piece of his skull. It would be easy to multiply such instances, but enough has been said to shew the difficulty of delivering a correct opinion on the nature of injuries, before the event occurs; and, after that, in tracing the death of the individual to the injury which he has received. In this country, however, the criminality and the punishment do not always depend on the fatal issue of a wound; for by an act of the legislature, usually termed Lord Ellenborough's act, the infliction of a wound with intent to kill is deemed felony, although death may not be the result. (See Russell, p. 594—and, for the alteration of the statute, xvi). But frequently this evil intent can only be inferred or disproved by the nature of the injury; and consequently the evidence of the surgeon, or medical man, is still of much importance; and, on giving an opinion, it behoves the medical witness not merely to inspect the wound, and discover its nature, direction, and connexion with internal lesions which may be found on dissection, but to take into account the influence which *age*, *constitution*, *temperament*, *health*, the *vocation* of the wounded person, the *place* of his *residence*, the *weather*, the *time* at which surgical aid was procured, and the *kind* of *aid*, *skilful* or *otherwise*, would have on the issue. It is even necessary to look at the relative

strength of the wounded person, compared with other individuals of the same age; and whether any peculiarities of structure exist, which can explain the fatal event, in the particular case under examination; for death may follow very slight causes where such peculiarities exist; and nothing would be more inconsistent with justice than to punish an act which, under ordinary circumstances, would not have been regarded criminal. Thus, in a case referred to by Dr. Paris, a boy died of fracture of the skull from a chastisement inflicted upon him by a man who caught him in the act of robbing his orchard. On the trial, it was clearly proved that the size of the stick was not such as to have occasioned any fracture, had not the skull of the boy been *unusually thin*; and upon this evidence the man was acquitted of the felonious part of the charge, as no evil intent could be proved. It is evident, therefore, that a wound may prove fatal in one person, which would not be even dangerous in another; the danger, also, may depend less on the degree of severity of the wound than on the part of the body wounded, and not unfrequently on the treatment adopted. In giving evidence, therefore, in cases of death or extensive injuries from wounds, the medical man has no general rules to guide him, but each case must be examined upon its individual merits. I shall suppose a case, and point out to you the peculiarities to be attended to in its investigation.

First, with regard to *incised and punctured wounds*. Two men quarrel, and in wrestling one of them takes a knife from his pocket, or, if a soldier, a bayonet from his side, and inflicts a wound or wounds upon his opponent. In such a case, death may follow immediately, or in a few days, or life may be placed in great danger, and yet recovery take place, or no apparent danger may be obvious at the time, and nevertheless the man may apparently die of the injury he received from the wound. In the first instance, questions may be raised whether the death was the result of the wound, or the effect of the falls on the ground during the scuffle; or whether a similar wound would have proved fatal, had the individual not been under the excitement of anger at the instant of receiving it. If the wound be in the neck, and the carotid divided; or in the groin, and the femoral artery be opened; or if it have penetrated the thorax, and into the heart or the aorta; if the par vagum on either side be divided; or if the abdominal cavity be laid open, and the stomach or any of the viscera extensively wounded, and the individual die in a few minutes, the mortal characters of the wounds can leave no doubt that they are to be regarded as the cause of death; but if this be delayed for some hours, and the wounds be not very conspicuous, then the opinion respecting the cause of death becomes more difficult, and

involves several considerations. If the head be the part wounded, and the knife or the bayonet have penetrated to the bone, although the wound be scarcely perceptible, the most severe inflammation may be set up, and death be the consequence of a wound apparently slight; for a complete division of the pericranium is much less to be dreaded than a wound from a sharp pointed instrument penetrating to the bone. If the wound on the head arise from a fall, and a portion of the integuments be stripped from the bone, there is often less danger than from a punctured wound. This fact is well illustrated by a case quoted in the notes to Dr. Darwall's edition of Dr. Beek's Elements:—a drunken soldier fell from a waggon, the wheel of which, passing obliquely over his head, stripped the whole of the integuments off one side of it, leaving the bone completely bare. The integuments were replaced, and secured by stitches and bandages. The soldier travelled four days on the waggon before he was put into the hospital; and in less than a fortnight he was able to resume his duty. From these facts we are to draw this inference, that when giving evidence with regard to incised or punctured wounds of the head, we must explain to the court the uncertainty of the result in all such cases; and that no inference can be drawn from the extent of the wounds, as the largest wounds of the head are by no means the most dangerous. On the same account a cautious prognosis is to be given, even when the wound is apparently what is termed slight, as erysipelas may supervene, and, if communicated to the membranes of the brain, certainly prove the cause of death. (Case in Times.)

The same caution is required with regard to wounds of the face. The point of the knife may have entered the orbit above the eye, and penetrated to the brain, and become the cause of death, although scarcely any external wound is perceptible: on the other hand, there are instances on record, in which sharp instruments have penetrated to the brain, and yet no bad effects have followed. A remarkable case of this kind came under the care of Mr. Liston. The man to whom it occurred was blasting the roots of trees, when a splinter was driven into the eye, which, from its length, must have penetrated through the foramen opticum into the brain. Some time afterwards this splinter was removed by Mr. Liston, and the man recovered. In the same manner much obscurity may be produced if the instrument have penetrated to the brain through the nose, unless death immediately ensue, and the fact be determined by dissection. In the majority of instances, however, wounds of the face are not dangerous, and yet death may result without any other apparent cause. In such cases, a medical witness would ill perform his duty were he to confine his investigation to the wounds them-

selves: he must examine the whole of the head, first externally, to ascertain the existence of any bruises, and then internally, to see whether effusions of blood between the dura mater and the skull correspond to the external bruises, in which case the danger must be attributed to the *falls*; or, even if no external bruises be evident, and effusions of blood be found on the membranes, or in the substance of the brain, still this may arise from the shock of a very slight fall, or even from a blow, rupturing the vessels. This fact is well illustrated in a case mentioned by Mr. John Bell, in his work on Anatomy. A woman, whose child was ill, went down stairs in the dark to procure some water, and slipping on the last step, came down upon her heel. She felt no great inconvenience from the shock at the time, and returned up stairs with the water. She had, however, scarcely entered the room ere she staggered, and supported herself for a few minutes on a chest of drawers, then sunk to the ground, and instantly died. On opening the head a vessel was found ruptured, the effusion of blood from which into the substance of the brain was the immediate cause of death.

Although extensive wounds of the neck, in which the carotids, the internal jugular veins, or the pharynx, or the œsophagus are divided, such as are inflicted either by the murderer or the suicide, must always be regarded as dangerous; yet we are not to be guided, in pronouncing an opinion, solely by the extent of the injury, and the nature of the parts divided. The wound inflicted in the neck may be scarcely perceptible, or be in a place where little danger is feared, and nevertheless may prove soon fatal. Sir Charles Bell, in his Surgical Observations, mentions the case of a suicide who made six slight cuts on the fore part of the larynx, and although no considerable branch of the thyroid artery was divided, yet he bled in secret for three hours, and died of the hæmorrhage.

The prognosis of incised or punctured wounds of the thorax is always doubtful, if the instrument have entered at the upper part of the thorax, or at the posterior side near the junction of the ribs with the vertebræ: but it is the universal opinion of army surgeons, that wounds of the thorax, whether incised or punctured, ultimately do well, if the hæmorrhages be not of so deadly a nature as to prove fatal in forty-eight hours: even the heart has been slightly wounded by a sharp instrument thrust into it, without proving mortal. From these and similar facts, the medical witness is authorised to speak with more confidence of recovery from incised or punctured wounds of the thorax, than those of the head or neck. Many instances have been recorded of recoveries from apparently desperate wounds of the lungs; thence the impropriety of decidedly declaring any wound of this descrip-

tion mortal or highly dangerous; but, on the contrary, holding them up as seldom terminating fatally in a healthy state of the habit, unless some large vessel, or other primary organ besides the lungs be wounded. Wounds, however, on the surface of the thorax, which are not at all of a threatening nature at first, often unexpectedly have a fatal termination. Thus, in such a scuffle as I have imagined, if the knife or bayonet enter from behind, and directly open the infra scapular vessels, although externally very little or no hæmorrhage may appear to the eye, yet the blood may be poured out and may find its way down to the loins by infiltration, causing there deep abscesses, gangrene, and death. Hence the greater necessity of a cautious prognosis in some cases where the cavity of the thorax has not been entered, than in many in which it has been deeply penetrated.

In a case detailed in the *Times* newspaper (January 29), a man of the name of Jenkins was stabbed, and died in two days afterwards. The report of the surgeon, Mr. Jones, who attended and examined the body, is—"that the knife had passed obliquely through the integuments between the 7th and 8th ribs; the orifice on the inner side being half an inch nearer the median line than the one on the outside, and had penetrated the diaphragm, causing an effusion of blood in the cavity of the abdomen and the chest." The vessels divided should have been mentioned, although it would not alter the correctness of the opinion that the internal hæmorrhage was the cause of death. "The instrument," says Mr. Jones, "which caused the wound had been introduced obliquely from the left to the right side." This observation is a valuable one; yet, in answer to a question from a juror, "Was it likely he could have inflicted the wound himself?" Mr. Jones answers, "It might have been." Now this is not very probable, unless he were a left-handed man—an important fact, which should be ascertained before the trial.

All incised or penetrating wounds of the abdomen, whether of the containing or contained parts, require a doubtful prognosis, being always dubious in their results. More is to be dreaded from inflammation than protrusion of intestines; yet the singular recoveries that have been recorded from the severest wounds of the abdomen, should at least teach us caution in hazarding an opinion upon the result of these cases. Dr. Hennen, in his Military Surgery, mentions the recovery of a soldier, whose abdomen was penetrated by a ramrod, fired from a musket: it had passed anteriorly, and actually stuck in one of the transverse processes of the vertebræ, from which it was not disengaged without the application of some force. When the instrument has penetrated the stomach itself, it is scarcely possible to doubt that blood-vessels and nerves must be injured; thence, it cannot

be regarded otherwise than at least hazardous. If the stomach be full at the time the wound is inflicted, it is more dangerous than when the viscus is empty: it should always, therefore, be a subject of inquiry, how long before the injury a meal had been taken, as this should guide our decision. Wounds of the intestines are less hazardous than those of the stomach, unless the small intestines be penetrated: the greater risk in these seems to depend on their greater irritability, and the greater number of nerves sent to them. Fodère mentions a case where instant death was caused by a slight prick in the small intestines, from a butcher's knife, although little blood was effused. The degree of danger connected with wounds of the fixed viscera of the abdomen depends very much on the injury done to the principal vessels supplying them with blood. In females, if the uterus be wounded in the impregnated state, the danger is much increased. In every wound of the abdomen, the nature of the extravasated fluid is particularly to be taken into account: whether blood, bile, fœcal matter, chyle, or urine. With the exception of blood, which, in a certain degree, is within the power of the surgeon, the pouring out of these fluids into the abdominal cavity is always productive of danger, and of dubious result, by the inflammation which is induced by them on the serous membrane.

Little is required to be said respecting wounds of the extremities, whether incised or punctured: the danger of all wounds being lessened in the direct ratio of their being within the power of the surgeon. Simple wounds, however, even of the extremities, are not wholly free from risk: thus, a cut across the abductor muscle of the thumb may prove hazardous, from the tendency of wounds in that muscle to induce lock-jaw: and wounds of veins, in some conditions of the habit, almost invariably prove hazardous.

Such are the circumstances to be attended to in delivering a prognosis respecting incised and punctured wounds, when these are the subjects of medico-legal inquiry. The subject can only be very briefly and imperfectly sketched in this place; it involves details of surgery, which it is not my province to enter upon; but without a competent knowledge of which, no man can be regarded as a medical jurist. When wounds of this description are even slight—that is, when no parts, important in carrying on the vital functions, are involved in the injury—still, under certain circumstances, we ought not too hastily to form a decision as to the issue. A wound, apparently very slight, may not be wholly devoid of danger; and when death follows a wound at the distance of several months, it becomes an object of the first moment to determine whether death, in this case, is to be attributed to the wound, or to some cir-

cumstance connected with the habit or condition of the person, or the management of the wound. Sir Charles Bell has recorded a case of this kind, although the wound was inflicted by the person herself. "A young woman, in phrenzy, plunged a pen-knife into her throat. The point of the knife pierced the upper part of the thyroid cartilage, so that it entered at the union of the chordæ vocales. She was suffocated at the distance of some months, by the granulations which arose from the edge of the wound, and which filled up the passage of the glottis. The patient in the meantime had gone about her usual occupations." In another case, which also survived some months, the man at length died of suffocation, produced by the knife, with which he cut his throat, having so divided one of the arytenoid cartilages, that a portion hung by a membrane, so as to vibrate in the chink of the glottis, like a pea in a cat-call, and acting as a foreign body, caught in the rim of the glottis, and occasioned suffocation. In both of these cases, had the wounds been inflicted by other hands than those of the individuals themselves, charges of murder would have been properly made against the parties, and would have evolved an argument of high legal interest.

If, instead of *incision* or *puncture*, the wounds be *bruises* or *contusions*, the same precautions in finding a prognosis are requisite. They are more obvious than incised or punctured wounds, from the discoloration of the part, arising from the violence of the injury which it has sustained, producing an effusion of blood. But the results of severe mechanical shocks are not always so conspicuously traced. A blow on the region of the stomach will frequently produce death: no appearance of change or bruise is seen on the surface, but the stomach, when examined, displays a red, inflamed appearance, which has been attributed to the sudden cessation of the action of the heart producing the settling of the blood in the extreme arterial branches; sometimes they are accompanied by laceration, in which case they are attended with hæmorrhage. In some instances, the blow which causes death is so trifling, that it is difficult to fix the degree of guilt that should be attributed to the aggressor. Two cases of this description are noticed by Dr. Paris, which I will read to you. (See vol. ii, pp. 122, 123).

In lacerated wounds the hazard is generally in proportion to the extent of the exposure of the denuded surface to the air, and the risk, which not unfrequently attends them, of tetanus supervening.

With regard to gun-shot wounds, the chief object, in medico-legal inquiries, is to ascertain the course of the ball, both in determining the degree of danger, and the fact as to the direction in which the shot was

fired; on which, in numerous instances, guilt has been brought home to the accused; and in some cases the innocent, who would otherwise have been unjustly condemned, have been fully and satisfactorily exculpated.

The course which balls take is most remarkable. "A ball," says Dr. Hennen, "will often strike the thorax or abdomen, and, to an inexperienced eye, will appear to have passed directly across, or to be lodged in one of the cavities:"—yet, perhaps, we shall find that it has coursed along under the integuments; and sometimes, after having nearly completed the circuit of the body, is found close to the point of entrance. Dr. Hennen illustrates this remark by a very singular instance, which occurred to a friend of his in the Mediterranean. "The ball, which struck about the pomum Adami, was found lying in the very orifice of its entrance, having gone completely round the neck." This circuitous course of balls occurs even in cases of suicide, when the pistol is placed close to the body.

Many years ago, I was desired to see a gentleman who had shot himself. I hurried to the house, and found the person lying on his bed-room floor, with his servant supporting him, and a pistol close to him. He was pale, trembling, and apparently dying; and he assured me that all assistance on my part was vain, as he had shot himself through the heart. He was raised upon his bed and stripped: he breathed freely: very little blood was upon the shirt, none was expectorated, and none at the point where the ball had entered, which was over the sixth rib. I therefore suspected that it had not entered the thorax, but had struck the rib and coursed round it, which, on examination, proved to be the case, as I found it under the scapula, near the lower edge of the bone. That bone was fractured, and, therefore, I had little difficulty in extracting the ball. I need scarcely add, the gentleman recovered: he is now alive, and in possession of a title and a large property.

The most singular instance mentioned by Dr. Hennen, is one in which a ball, which struck the breast, lodged in the scrotum, the man standing erect in the ranks. Nothing is of more importance than a knowledge of these facts, in a medico-legal point of view. A man is shot, the ball is said to have passed through the thorax, and he is reported to be in the most imminent danger; yet he displays no great difficulty of breathing; there is no hæmorrhage from the mouth; no deadly faintness, nor coldness of extremities, nor labouring pulse, has taken place. In such a case, there is every reason to believe that the thorax has not been penetrated. Sometimes its course may be traced by a peculiar dusky line, terminated by a tumour, where the ball is lodged; but this line is not always obvious. The direction which a ball takes is often the best evidence whether in-

tention or accident occasioned the shot. In a trial for shooting a poacher, it was satisfactorily proved that the direction of the ball being upwards, the fowling-piece had not been levelled from the shoulder, which would have implied an intent to kill, but must have been discharged at the trail, and consequently the wound which caused death must have been accidental. This evidence, which was given by the surgeon who examined the wound, was sufficient to convince the jury, who brought in a verdict of *chance-medley*, and the panel, Richard Annesley, was accordingly discharged.

Enough has been said to convince you, Gentlemen, of the importance of an accurate inquiry into every circumstance connected with wounds, before pronouncing any opinion either on the degree of danger connected with them, or whether they have been actually the cause of death. In the event of a fatal issue, the inspection of the body should take place as soon as possible; and no morbid dissection requires to be conducted with so much delicacy and care, as that which is intended to establish a connexion between an external lesion and an internal injury, with which it may be complicated. In proceeding to the inspection, if the death have proceeded from a shot, the first object is to ascertain the place where the ball entered, and its direction; or, if the death have not proceeded from fire arms, to examine carefully the more superficial lesions, as these are likely to be either effused or changed in character as the decomposition of the body advances. It is of little consequence in what part of the body the wound might have been inflicted: every cavity ought to be examined. In considering the particulars to be attended to in such a dissection, I will not occupy your time with any useless details.

If death have been the consequence of a scuffle, or if blows on the head have been given, the first object, after the integuments of the head have been turned back, is to ascertain that there is no fracture, and whether there be any diseased state of the bones. If any appearance of fracture display itself, it must be determined whether this may not have occurred after death, which will appear by the blood not being coagulated round the fissures, nor upon the bone. On raising the skull-cap, its inner surface must be carefully examined, to see that it is not in a state of caries, or whether there be any exostoses. In a trial at the Devon Assizes, in 1800, Thomas Bowerman was accused of murdering Mary Gallop, a bastard child of his wife, by pushing an awl into her skull. The head was examined, and a small hole was said to be discovered on the side of the head near the ear, which had been pointed out as the spot by the mother of the child. Mr. Sheldon, the anatomist, who, fortunately for the accused, happened to be at Exeter at the time, demonstrated to

the coroner and the grand jury, that this was a natural perforation, with a smooth polished edge, not uncommon in skulls. On this testimony, the grand jury returned "No bill." If coagulated blood be found on the surface of the *dura mater*, it indicates external violence, although it be not opposite to the place where a bruise appears on the integuments. Sometimes it is on the hemisphere opposite to the side on which the blow was struck, forming what the French term *contre coup*. The state of the *dura mater* itself must next be carefully examined, to see whether it contain an osseous deposit, or exhibit any diseased alteration of texture, as these may occasion rupture of vessels, which would not follow a fall or slight blow in a healthy state of the membrane. The transparency and regularity of surface of the arachnoid coat must be noted, and whether any fluid be effused under it. It is of some importance to distinguish between that gorged state of the arteries of the *pia mater* which indicates that inflammation had existed there, and the turgid state of its veins, which not unfrequently occurs in cases of impeded cerebral circulation: nor must the gravitation of the blood, according to the position in which the body has been lying, be mistaken for congestion.

In cases of sudden death, in a state of health, the ventricles of the brain contain no fluid, except as much as merely serves to lubricate them; if any protracted disease have existed previous to death, more or less fluid is generally found in them. Too much care cannot be bestowed on the inspection of the brain, its consistence, the state of its vessels, and whether it be devoid of abscesses, tumours, extravasated blood, or hydatids: for if these exist, very trivial blows may be productive of fatal effects. On removing the brain, the base of the cranium must be carefully examined, as fractures may exist there, which might escape notice. (See illustration in a curious case published by Sir C. Bell, Obs. p. 469). This case shows, also, the necessity of examining the cervical vertebrae: for although dislocation of these cannot occur without displaying symptoms which indicate it during life, yet fractures may exist, which tend to throw light on the subject of inquiry.

In opening the thorax, the greatest care must be taken to avoid puncturing the pleura, or the pericardium. Our first object is to ascertain if fluid be contained in the chest, and whether this be limpid, tur-

bid, or flaky; next, the colour, general appearance, and capacity of the lungs must be ascertained; whether they are gorged with blood; crepitous and light, or dense, and sink in water. Violet-coloured spots on the surface, and ecchymosis, are indicative of some violent effort preceding death. The heart should be examined both in situ and out of the body, first securing the blood-vessels with ligatures. The quantity of blood contained in its cavities; the colour of the fluids and liquidity, or coagulation, should be noted; and the state of the valves. From ossification of the latter, the life of an individual is placed in great jeopardy, and instant death may follow even a moderate effort; and the same may be the case in ossification of the aorta: so that a man in wrestling may drop down dead, without any blow or injury from his opponent.

The examination of the abdominal cavity is of great importance in cases of death from wounds. Any perforations in the stomach must be particularly investigated, to determine whether they are the results of punctured or incised wounds, or of the causes which produce spontaneous perforations of this viscus. The state of the villous coat must be fully understood, lest colouring from ingesta be confounded with signs of inflammation. No part of the intestinal canal should be overlooked; and you should bear in recollection that the death of an English sovereign, Edward the Second, was caused by a hot poker thrust up the rectum. The division of any of the lobes of the liver must not hastily be referred to wounds of a cutting instrument, for cases of falls are recorded, in which this has occurred. In one of these, detailed in the 3rd vol. of the Trans. of the College of Physicians, the right lobe was divided in an oblique direction, through its whole substance, from its extremity on the right side to the border of the left lobe.

Such is the manner of examining a body of a person suspected to have been murdered, or whose death has been the effect of wounds. No opinion from the appearances should be hastily given: and a variety of considerations are necessary to be taken into account in determining the extent of blame which can be attached to the accused, even when the post mortem examination of the body seems to bear out the truth of the accusation.

LECTURES ON THE INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF
MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE XVII.

Question of the Seat of Irritability—whether in the Fluids or in the Solids—(continued).

THE principal arguments adduced in favour—not of the inherent life, for that implies an absurdity—but of the inherent vitality of these fluids, or their competency, upon the application of the requisite stimuli, to manifest vital phenomena are, 1. That these fluids are as essentially a constituent part of organized beings as the solids, and therefore may be *a priori* regarded as equally possessed of vitality. 2. That it is of one or other of these fluids that all the organized tissues are directly composed, and that what imparts vitality to other things cannot be supposed to be itself destitute of it. 3. That these fluids have the same ultimate globular structure as the organized tissues, such globules being every where presumed to be organic molecules, and as such possessed of *l'aptitude à vivre*, or vitality. 4. That the chemical composition of these fluids is similar to that of the organized tissues, and that they resist, like the latter, during the continuance of their vitality, the influence of common chemical agents, as manifested by their remaining fluid in spite of their fibrin, and by their not undergoing putrefaction. 5. That they evince sensible motion, as actuated by their own proper stimuli, without deriving any part of this motion from the action of the solid parts, as is obvious from the facts that in some of the lower animals there are no containing vessels, that in all embryos and new growths the vessels are formed subsequently to their future contents, that these fluids continue to be circulated in cases in which, from monstrosity or disease, the action of such vessels must have been impossible, and lastly, that such inherent motions may, under favourable circumstances, be observed in them after removal from the body (*a*). 6. That these fluids display phenomena from the action of certain stimuli, such as the venom of the viper (*b*), analogous to those displayed by the solid parts, and dependent in the latter certainly upon their vitality. 7. That, under the ordinary circumstances of death, they coagulate upon the same principle as the muscles become stiff, by their vital contractions excited by “the stimulus of death,” whereas when an animal has been killed by violent exercise, or any of the other causes of sudden death elsewhere enumerated, they fail to coagulate for the same reason as the muscles, under these circumstances, fail to stiffen. 8. That even after coagulation, they actually betray, like the organized tissues, when acted upon by certain stimuli, sensible vital contractions (*c*). 9. That if they have been once frozen—that is to say deprived of their vitality—like an egg or any other organized substance which has been treated in the same way, they more rapidly undergo this process upon being again exposed to the requisite degree of cold, than they did the first time.

Now to the first of these arguments it may be replied that it is no more applicable to the fluids under consideration than to the various secreted fluids, few or none of which, except the genital fluids—the fallacy respecting which has been already alluded to—have been commonly presumed to be possessed of vitality (*d*). To the second, that it is not of any one of these, fluids nor of any pre-existing ingredient in them, that the organized tissues are directly composed, but of a proper secreted matter, or organized germ, in forming which, in all probability, these fluids did not act as instruments, but were merely acted on as materials; and that it is in virtue of its organism alone, and not in virtue of any thing derived from them, that this new matter possesses vitality (*e*). To the third, that the

(c) Tourdes and Circaud.

(d) Albinus indeed, and some few others, have attributed life to all the fluids of the body, the excrement inclusive; and the advocates of the doctrine of the identity of the globules of extractive, sodo-albumen, and the other reputed proximate principles of organized beings and organic molecules, must necessarily concede to them all, if not

life, certainly vitality.

(e) The practice hitherto so common, not only with chemists, who might have been excused, but with physiologists, of speaking of the serum of dropsies, the lymph of adhesions, the callus of bone, and so forth, as merely *ready-made ingredients* of the blood, which, under certain circumstances, are effused, and the two latter of which are afterwards inspissated by coagulation, instead of regarding them as perfectly *new matters*, which, under certain circumstances, are secreted, and the two latter of which are aft

globules alluded to, while they are found in many secreted fluids, of the vitality of which no suspicion has been usually entertained, have never been detected in the organized tissues—admitting that they exist in them at all—till they have lost their vitality, so that their presence in the fluids in question is rather unfavourable than the reverse to the presumption of their possessing vitality—that such globules moreover are not organic molecules has been already sufficiently insisted on. To the fourth, that if these fluids have the same chemical composition as the organized tissues, they in all probability contain no ready-made fibrin, so that their not coagulating, while in the course of circulation, is no proof of their resistance of ordinary chemical agents, since they can have no more tendency to do so than the still organized muscular tissue; nor is the presumption of any such resistance on the part of these fluids, founded upon their either not coagulating, or not putrefying, while in the course of circulation, at all necessary, even admitting them to contain fibrin, sodo-albumen, and so forth—as we must do if we deny them vitality—since the fibrin, as before remarked, is never, under these circumstances, for a sufficiently long time identical to allow its property of spontaneously coagulating to manifest itself, nor, *à fortiori*, is either this or any other proximate principle of these fluids ever sufficiently long the same to admit in them of the putrefactive process. To the fifth, that these fluids, although in quite the lowest animals, in the early embryo, and in new growths, not contained in obvious vessels, may still owe what little motion they display to the surrounding solid parts, and that there is certainly no proper circulation of these fluids till a distinct vascular system has been established, which moreover may in many cases exist although not yet discovered (a); that in all recorded cases of monstrosity or disease the continuance of the circulation may be satisfactorily explained upon the presumption of certain parts of the vascular system having become vicarious of others; and that all the appearances of spontaneous motion in these fluids, when withdrawn from the body, may be fairly referred, like the shooting of a crystal from its solution, to processes preliminary to their coagulation or other physical changes, particularly as very similar motions have been noticed in numerous other fluids besides those under consideration. To the sixth, that the phenomena manifested by these fluids on the application to them of certain agents consist principally in their coagulation, which is not a vital, but a strictly chemical process. To the seventh, that as the stiffening of the muscles, in cases of death under ordinary circumstances, pretty certainly depends, as has been elsewhere shown, on a strictly chemical process supervening upon the cessation of their vitality, the analogous action of the blood is rather hostile than favourable to the notion of its being possessed of this property; and that the continued fluidity of the blood and flaccidity of the muscles, in cases of sudden death, are explicable also on purely chemical principles can hardly be questioned. To the eighth, that the assertion that these fluids are capable of effecting vital contractions after coagulation is not only false, but absurd, since it would go to prove, not only that they were alive, but that they were alive after they were dead, their coagulation, be it remembered, having been already attributed to the stimulus of death. Lastly, to the ninth, that the more rapid freezing of these fluids the second time than the first may be easily explained upon the presumption of numerous physical changes which they may in the meantime have undergone, without having recourse to any changes resulting from a loss of vitality.

It seems then that all the commonly alleged arguments in favour of the inherent vitality of all or any one of these fluids are more or less fallacious, and consequently that they may be safely regarded as destitute of this property—the more especially as the presumption of their vitality appears to be as totally uncalled for as that of any of the other fluids of the body. It is with the heart alone, or corresponding organ, and its immediate appendages, the arteries, veins, and lymphiferous and chyliferous vessels, with the parenchymatous and erectile tissues, that these fluids, all or any of them, come into contact. Now, the heart or corresponding organ, as the centre of the circulating system, and parenchymatous tissue, as the seat of nutrition, secretion, and absorption, are as certainly muscular, and therefore as capable of acting on their contents, as the parietes of the chest, the stomach and intestines or the uterus; and it is manifestly inconsistent to believe that in the former cases the organs require the co-operation of their contents in order to perform their functions, while in the latter they do not.

We appear to be justified then in concluding from all that has preceded, that irritability, or vitality, the primary condition of life, and the predisposing cause, as it were, of

wards solidified by their plastic force, is happily losing ground. It is impossible that any precision can be maintained in the science of physiology, so long as processes and substances so totally unlike each other as the effusion of coagulable lymph, and the secretion of an organized germ continue to be called by the same names.

(a) How recently, for example, has the beautiful vascular system of insects been satisfactorily demonstrated; and how probable is it that a Newport or an Ehrenberg will in future detect distinct vessels in forms of being which appear hitherto to be utterly destitute of them.

all the functions in the sum of which life consists, resides exclusively in the organized solids; and that it is by the action of these alone that all the vital movements, whether molecular or sensible, are effected (a). Further, it is manifest from the endless modifications of the vital movements, not only of different organized beings, but of the different organized solids of each, as excited by the same stimuli applied either to different plants and animals, or to different parts of the same, that every organized solid is not only the seat

(a) Among those who, like almost all the ancient physiologists, as well as so many of the modern, looked upon life as something elementary, and, as it were, ready-made, it was not possible that irritability or vitality, an ingredient only, if it may be so called, of life, and requiring to be compounded with others before it can give rise to vital phenomena, could attract any attention; nor can it be said that their *Πορ καθαρσιον κ. τ. λ.* was synonymous with what has been since called irritability, when it is remembered that the former was regarded as a substance, the self-sufficient cause of living action, while the latter is considered as merely a property, and one condition only of such action. The term irritability was used for the first time by Glisson, about the middle of the seventeenth century; and is by him defined to signify the faculty of perceiving a stimulus, in contradistinction to sensibility, which is defined to signify the faculty of perceiving a perception. "Irritatio," says Glisson, "est Perceptio, sed Sensatio est Perceptio perceptionis" (*De Ventriculo et Intestinis*, 1678, p. 239)—a definition which for either terseness or accuracy cannot perhaps be improved. In the same track, and equally with reference principally to the irritability of man and the higher classes in general of organized beings—in which alone there is any occasion for contrasting it with sensibility—followed Baglivi (*De Fibra Motrice*, &c. 1703)—De Gorter (*Medicinæ Compendium*, 1731)—Winter (*De Certitudine in Med. Prac.* 1746)—Lups (*De Irritabilitate*, 1748)—F. Hoffman (*Med. Rat. Syst.* 1750)—and many others; but the laws of irritability were investigated with so much more care and precision by Haller and his pupil Zimmermann (*De Irritabilitate*, 1751), that the labours of all preceding physiologists became obscured, and the whole doctrine of irritability has been since inseparably connected with the name of Haller. It must be remembered however that the irritability of Haller—or, as he sometimes called it, *Vis Insita*—was not precisely that of most of his predecessors; the latter having commonly used the term in the general sense above adopted, while by the former it was confined to the susceptibility of movement in the more obvious muscles—the sensible contractility afterwards of Bichat—the laws of which alone could easily be made the subject of investigation. By Brown (*El. Medicinæ*, 1780), the faculty of irritability, in the most extended sense of the word, was in general amalgamated with every other analogous faculty, including

sensibility, under the general term excitability; but it was again distinguished by Girtanner, (*Sur l'Irritabilité*, 1790)—who once more employed the term, not in the restricted sense of Haller, but in the comprehensive sense in which it had been employed by Glisson, and while he conceded more or less of this faculty to all the organized solids as well as to the more obvious muscles, regarded like some others the *Vis Insita* of Haller, or that faculty by which these organs contract upon the application of stimulus to themselves, as only one of several kinds of susceptibility of which they were possessed, such as a *Vis Tonica*, a *Vis Nervosa* and a *Vis Animalis*, or distinct faculties of contracting either upon being mechanically distended, upon the application of a stimulus to their principal nerves, or as acted upon by volition. Concerning the whole of this doctrine however, it is sufficient to observe, once for all, first, that these so-called *Vires* are not *Vires* or powers at all, in the physiological sense of the word, but properties or faculties; and secondly, that, as resident in the same organ, they are no more distinct from each other than the property by which the stomach acknowledges the stimulus of various kinds of ingesta, and that we might with equal propriety attribute to the latter a *vis panaria*, a *vis casea*, and a *vis carnea*, because it acts equally well on bread and cheese, and on beef-steaks. By Blumenbach (*Instit. Physiol.* 1786), as by Haller, the term irritability is restricted to the susceptibility of movement in the more obvious muscles, which is otherwise called by him *Vis Muscularis*; while that in the insensible muscles or parenchyma—the Tonicity of Stahl, Whytt, and Cullen, and the Insensible Contractility of Bichat—he calls simply Contractility or *Vis Cellulosa*. With Chaussier again (*Exposition*, &c. 1807), the term irritability includes the susceptibility of movement, not only in the obvious muscles, but in the insensible muscles or parenchyma likewise, the former of which, however, he characterizes by the specific appellation of *Myotility*, and the latter, like Blumenbach, by that of Contractility properly so called. But there is no end to the different meanings attached to the word irritability by different physiologists, to say nothing of pathologists, who, from the time of Gaubius, have added to the confusion by continually using the word in a morbid sense, or of moralists, who apply the same term to a certain state of the temper and disposition. There seems to be no advantage however, but, on the contrary, very great inconvenience, in th

of irritability in general, but has a kind of irritability peculiar to itself; a fact the knowledge of which is of the most essential importance in physiology, since it is upon this principle alone that we are enabled to explain the specific effects, not only of their natural stimuli on different organized beings, and on the different organs of each, but also of numerous preternatural agents, whether deleterious or salutary (a).

endless invention of new terms, to which modern philosophers have been in general so prone, and by which many, who are incapable of distinguishing themselves in any other way, have sought distinction. Many better and less equivocal terms than irritability might unquestionably have been originally invented to express the faculty under consideration; but no man has a right, in the present day, to expect that his new nomenclature, however abstractedly excellent, will entirely supersede the employment of a term already in general use, and, if this be not the case, it can only do harm by adding to the publicity. Perhaps the dentifrangibulous names, "Metatarso-sub-phalangei—transversales—pollicis—pedis" and "Broncho—laryngo—tracheitis—

Perceptivity, without
movement at all (?)
Perceptivity, with insensible

{ Haller.
Blumenbach.

In the present instance, the term irritability is always employed in its most extended physiological application, as synonymous with vitality, and signifying the susceptibility of undergoing, on the application of a stimulus, any change, which, as not strictly either chemical or mechanical, is characteristic of organized beings.

(a) The doctrine of specific kinds of irritability, as manifested by man, was perhaps better understood in ancient times than that of irritability in general; the necessity for admitting the latter, as a condition of vital action in general, having been superseded by the invention of the vital principle, whereas the peculiarities in the actions of different organs, under precisely the same circumstances, could not be got over without the admission of some modifying agent of this description. These specific kinds of irritability accordingly very soon occupied a prominent place in systems of physiology. They were alluded to first under the name of Genii, or Demons, or Decons of the air, which the ancient Egyptian Pastophori, and their immediate pupils, the first Greek philosophers, supposed immediately to preside, under the control of the great master spirit, or vital principle, over the function of each particular organ of the body; and a remnant of this absurdity is still perpetuated in some almanacs, in which the several members of the body are represented as under the especial care of certain planets. By Hippocrates and Galen, these specific kinds of irritability were called *Δυναμεις*, and were considered to reside, one or more in each organ, in subserviency to the grand

myxo—pyo—meningo—gene" may appear preferable—at least to persons with robust pteregoid muscles—to the terms "Transversi-pedis" and "Croup;" but they are not likely to be universally adopted; so that the onomatomaniacs, without obviating the necessity of our understanding old terms, only impose upon us that of learning new ones likewise. Names in general are

"Not bad *simpliciter*, nor good,

But only as they're understood;"

and it seems quite sufficient to establish any given name as the best, that it is generally employed, and by all who employ it once clearly defined. The following then is a summary of the more or less comprehensive physiological acceptance in which the term irritability is used by the authors above cited.

Ενορμων, or *Πνευμα*, and to be the immediate cause of the peculiar function which it performed. Thus the heart had, according to Galen, at once a *Δυναμις διαστελλομενη*, by which it attracted the blood from the lungs, a *Δυναμις περιστελλομενη*, by which it retained this blood for an instant, and a *Δυναμις συστελλομενη*, by which at length it drove it into the rest of the body; and it is in this fancy that the still employed terms diastole and systole of the heart originated. The arteries, in like manner, had a *Δυναμις ελκτικη*, *καθεκτικη* and *αποκριτικη*, by which they were adapted to their several supposed functions, and so of the stomach and other organs: all which, it must be confessed—for these *Δυναμεις*, be it remembered, were all *per se*—furnishes a very good example of the "vox et præterea nihil," by which pretended explanations of physiological facts are so often distinguished.

It was in ridicule of this that Dean Swift represents the action of a smoke-jack as depending on a meat-roasting power, and that of a fiddle on a tune-playing power; and that Molière makes his candidate for a physician's diploma reply to the question *Quapropter opium facit dormire?* *Quia habet vim dormitivam*. But if strings of words like these furnish no explanation of the peculiar facts in question, they are at least an acknowledgment of this peculiarity. In after times these specific kinds of irritability were understood by Van Helmont under the term *Archæi Insiti*, the number of which was almost infinite, but all were represented as held in subordination by the one sovereign *Archæus*, or the vital principle,

It is true some kinds of stimuli, such as caloric, appear to act almost indiscriminately upon all plants and animals, as well as upon all the organs of each; but such is not the case with by far the greater number of such agents—the blood for instance being adapted to the specific irritability of the heart and parenchyma alone, and the alimentary matters to that of the stomach and intestines, and the indirect stimuli of sympathy and passion having both, in every variety of each of them, their own proper organs on which alone they display any effects. And if this be the case with respect to natural stimuli, it is still more remarkably so with respect to such as are preternatural, every exciting cause of disease, on the one hand, and every agent employed in relieving such disease, on the other, by whatever avenue they may be respectively introduced into the body, operating each on those organs to the specific irritability of which they are severally adapted, while with respect to all the rest they are either wholly or comparatively inert (*a*). To this important principle it will be necessary to allude continually in future, but in the mean time this short notice of it must be sufficient, partly because any discussion of the question at all would involve the consideration of the action of the various stimuli by which irritability in general may be excited, and of which hitherto nothing has been said, and partly because a full elucidation of it would comprehend a multitude of facts each of which will fall to be considered much more conveniently elsewhere.

But admitting that irritability or vitality, general and specific, is a property of the organized solids alone, it becomes a question of the highest interest, whether it be directly inherent in each of the organized tissues, either of plants or animals, or whether it merely appear to be possessed by them all in virtue of some one which is universally distributed over the organized being, and inextricably interwoven with every other. The characteristic actions of organized beings in general have been all shown to consist in certain movements, molecular or sensible, and the only or chief immediate instrument of motion in the

whose court was in the stomach; and by Harvey again, under that of *sensus proprii*, resident one or more in each organ, and distinct from the *anima* which governed them all. Glisson also, with whom originated the doctrine of irritability in general, recognized in each organ a specific modification of this property under the title of *spiritus regens*, which, as he observes, "*aliud in Jecore, aliud in Liene, aliud in Pancreate, aliud in Ventriculo et Intestinis operatur.*" (*De Vent. et Intest.* 1678). The subject of these *imperia in imperio* was still further prosecuted by Bordeu, the father of modern French physiology, who distinctly propagated the doctrine that it was in virtue of its specific kind of irritability, "*que chaque organe sent et remeut à sa manière;*" (*Rech. Anat. sur les Glandes*, 1751), and who certainly suggested to Bichat all that the latter subsequently did in describing each organ as the seat of a *vita propria*, or specific modification of one or other of the two grand lives—the organic and the animal—under which he thought proper to arrange the functions in general. The term specific irritability, appears to have been employed for the first time by Dr. Farr (*on Animal Motion*, 1771), and it has been adopted by Sir Gilbert Blane (*On Muscular Motion*, 1788), and others; and the subject has been collectively treated of, perhaps in the most ample manner by Rolando (*Sur les Différentes Espèces de l'Excitabilité*, &c. 1822).

(*a*) The different character of the irritability of plants and animals is well displayed, among numerous other phenomena, by the very different effects upon the two of galvanism; that of the irritability of different plants by the often diametrically opposite effects upon any two of the same mode

of culture, and that of the irritability of different animals by the quite contrary effects on many of the inferior animals of some agents reputed by man wholesome or injurious. Thus parrots are poisoned by parsley, hogs by pepper, and fowls, dogs, and foxes by sweet almonds; whereas fowls are uninjured by dandelion, and pheasants by stramonium; hogs thrive on henbane, and storks, sheep and goats on waterhemlock; the last again are uninjured by tobacco, the wolf lastly is said to take white arsenic, and the horse corrosive sublimate with comparative impunity. In illustration again of the different character of the irritability of different organs in the same animal, besides the examples alluded to in the text, may be mentioned, among the exciting causes of disease, the action of the syphilitic or hydrophobic virus, to whatever part they may have been applied, the former on the tonsils, skin, and bones, the latter on the muscles of the pharynx, while all the other organs are comparatively unaffected; and, among remedies, that of the white or black hellebore, by whatever avenue they may have been introduced, the one on the stomach almost exclusively, and the other equally exclusively on the rectum. But even the same organ in different individuals of the same species often exhibits very striking differences in the character of its irritability—as connected with age, sex, temperament, idiosyncrasy, and habit of body—witness that of the stomach, which while in some persons it is turned by substances to most people highly acceptable, in others acts with energy on substances in general regarded as repulsive and disgusting. But the full consideration of this subject belongs to another place.

higher tribes of animals is sufficiently well known to be muscular fibre; but while, on the one hand, it is by no means certain—on the contrary, it is very improbable—that it is directly upon this tissue, and not rather upon the nervous, that the vital impression by which the muscular fibre is excited to action, is, in these cases, made, it is obvious, on the other, that, in plants and quite the lowest tribes of animals, we cannot regard irritability as seated in either a distinct muscular, or a distinct nervous system, since they appear to be, with very few, and these somewhat questionable exceptions, equally destitute of both. The possession by them of this property is nevertheless distinctly indicated, not only by all the vital actions which they, more or less, constantly perform, in common with the higher tribes of organized beings, but also by certain sensible motions which many of them display, on the application to them of a stimulus, apparently quite analogous to those which in the latter are effected by muscular contraction. Of these some of the best examples are afforded by the leaves of the Venus' Fly-trap (*Dionaea*), the Wood-sorrel (*Oxalis*), the Humble plant (*Mimosa*), and the Sun-dew (*Drosera*), as well as by the pistils of the Martynia (*Martynia*), and the stamens of the Barberry (*Berberis*), the Prickly Pear (*Cactus*), the Roman Nettle (*Urtica*), the Pellitory (*Parietaria*), and the Swallow-wort (*Asclepias*), all which appear to contract when a stimulus is applied to them; and how easily sensible motions may be excited by similar means in the Branched Polype (*Hydra*, 2), the Sea-feather (*Sertularia*, 3), the Sea-blubber (*Medusa*, 4), the Sea Hedgehog (*Echinus*, 5), and numerous other species among the lowest tribes of animals is sufficiently well known. It is probable, indeed, that many of these sensible motions are effected—as is known to be the case with those of the Humble Plant—by the momentary loss of balance in the distribution of the fluids through the parts manifesting such motions; so that it is by a kind of turgescence in one or other direction, like that which occasions the erection of the penis and other similar organs in the higher tribes of animals, that they are produced; but the action of the vessels, whence alone this loss of balance in the distribution of the fluids can result, does not less imply the possession of irritability than the contraction of the most obvious muscles. Irritability, then, is not the attribute only of a distinct muscular or a distinct nervous system, since it may exist independently of either; but, though neither of these systems may be so far developed in plants and the lower tribes of animals to deserve to be considered as distinct tissues, we are not, on that account, justified in denying that both may exist in them in a diffused and rudimental state, and that in this state they may be still competent to impart to the rest of the system that property which the higher tribes of organized beings derive from these tissues only when concentrated and perfect. If, then, the arguments in favour of the doctrine that either of these systems is, in the latter, the immediate seat of irritability appear to be well founded, we need have no hesitation in believing that it has a corresponding seat in the former; and should not certainly be deterred, as some have been, from regarding these arguments as tenable in their application to the higher tribes of organized beings merely because the muscular and nervous systems are so little obvious in the lower that they seem to be destitute of them, any more than we are deterred from admitting that the lungs and heart, because so little pronounced in some tribes of beings—which nevertheless respire and propel their fluids—as to appear to be wanting, are, in the higher tribes of animals, the chief instruments respectively of respiration and circulation.

Foreign Medicine.

Alum in Tonsilitis, &c.

M. VELPEAU, in a memoir on this subject, endeavours to show that the application of powdered alum applied by the finger to the inflamed parts, almost invariably cures acute sore throats in the space of a very few days. In proof, he quotes 40 cases, in which the efficacy of the remedy was not less extraordinary than rapid. Used for three or four days it is certain to put a sudden stop to the symptoms, provided there is no abscess of the tonsils; the fever decreases, the swelling diminishes, and the appetite returns.

In a second paper the same author mentions the benefit to be derived from alum in a disease not hitherto described, though of frequent occurrence. It consists in an acute inflammation of the bottom of the mouth and inside of the cheek, accompanied with

swelling of the surrounding parts, throbbing pains, inability to move the jaws, fetid breath, and sometimes fever. It is caused by a crushing of a portion of the mucous membrane between the molar teeth. Treated with emollients, bleeding, and other usual remedies, it may continue for a long time; whereas powdered alum brings it round in from two to four days.

[These memoirs are two out of four which M. Velpeau has presented to the French Institute as recommendatory certificates for admission to that body. The British reader will wonder to see a remedy so long used in this country for the purpose he mentions put forward as novel in France. Nor will he wonder less to hear so acute a surgeon as M. Velpeau certainly is, stating that gum-boil—for such is assuredly the last disease he speaks of—is a complaint not hitherto described.]

A NEW PRACTICAL FORMULARY

OF HOSPITALS, OR A

Collection of Formulæ of the Civil and Military Hospitals of France, Germany, Italy, Great Britain and Ireland, &c., containing the Indication of the Doses in which simple Substances, magistral and officinal Preparations of the Codex are administered, the use of New Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M. D., and P. VAVASSEUR, M.D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M. D. &c. &c.

(Continued from p. 313.)

[Ioduretted Sarsaparilla. (Magendie.)

Rx. Decoct. Sarsapar. Oij;
Potassæ hydriodatis, 3j;
Syrupi aurantii, 3ij.

To be taken in twenty-four hours.

Ioduretted Cynoglossus. (Magendie.)

Rx. Decocti cynoglossi, Oij;
Potassæ hydriodatis, 3ss;
Syrupi menthæ, 3ij.

Doses as above.

Employed at the Hotel Dieu in chronic rheumatism and chronic syphilitic affections,

Ioduretted Collyrium. (Magendie.)

Rx. Aquæ rosæ, 3vj;
Potassæ hydriodatis, gr. xxiv;
Iodinæ, gr. i—ij.

This solution is applied four times a day, in ulcerations of the conjunctiva and cornea in scrofulous habits, and a cure is effected in a month. Morphine is sometimes added. T.]

IODATE OF STRYCHNINE.

[This medicine is prepared by saturating powdered strychnine with iodic acid; it is then boiled in alcohol, filtered, and allowed to evaporate spontaneously. By this means we obtain a splendid crystallization of iodate of strychnine.

It is also prepared by double decomposition, by adding the iodate of soda in a solution of the sulphate or hydrochlorate of strychnine. The iodate is precipitated boiling alcohol is employed, and crystallization effected, as already stated. The action of this remedy is the most energetic, and it has been used by M. Magendie with great success in chronic paraplegia after all other remedies had failed. Dose, one-eighth of a grain in pills, one night and morning, increased to eight pills.

M. Magendie recommends hydriodate of potass in epilepsy, and I have given strychnine with decided success. It would, therefore, appear that the iodate of strychnine might be employed with advantage. T.]

BROME.

In large doses it is an irritative poison, whose action is similar to that of iodine; it

is employed like the last mentioned substance, in scrofula and hydrocele.

[M. Magendie employs it, when iodine does not evince sufficient action, or when the patient is accustomed to this remedy. He prescribes it in scrofula, suppression of the menses, and hypertrophy of the ventricles. (Formulary, March, 1835). T.]

INTERNALLY.

Aqueous Solution of Brome.

Rx. Bromii, 3ss;
Aq. destill. 3iss.

Four or five drops, progressively, are given in a glass of water.

HYDRO-BROMATE OF POTASS.

This preparation of potass possesses the same properties as the hydriodate; it may be employed as an antiscrofulous preparation, and as an emmenagogue.

INTERNALLY. Gr. iv—viij, daily, in pills.

Potion with the Hydro-bromate of Potass.

(Magendie.)

Rx. Potass. hydro-brom. gr. xij;
Aq. destill. 3ij;
Syrup althææ, 3i.

Fiat mistura, in die sumenda.

A spoonful at a dose.

EXTERNALLY.

Pommade of Brome. (Magendie.)

Rx. Potass. hydro-brom. gr. xxxiv;
Adipis, 3i.

Fiat unguentum.

Used in frictions, half a drachm or a drachm at a time, in scrofulous swellings,

Pommade of the Hydro-bromate of Potass.

(Magendie.)

Rx. Potass. hydro-brom. gr. xx—xxiv;
Liquoris bromii, gutt. vi—xij;
Adipis, 3i.

Fiat unguentum.

Employed as the preceding pommade. It is more active.

BROMATE OF IRON.

An energetic astringent, possessing the same properties as brome.

It is used in hypertrophy of the heart.

Pills of the Bromate of Iron. (Magendie.)

Rx. Ferri bromatis,
Gum. acaciæ, 3 3 gr. xij;
Confect. rosæ gall. gr. xvij.

Divide in pilulas xxiv, quarum sumat duas mane nocteque.

CHLORIDE OF GOLD.

In large doses it is a powerful corrosive poison, in smaller ones a general stimulant, whose action resembles that of corrosive sublimate, except that it acts less upon the salivary glands than that substance. It is used in constitutional venereal diseases where mercury fails, in scrofula, hydrocele, herpes, &c. The use of this substance requires the greatest caution.

INTERNALLY. Gr. 1-20th—1-16th daily, in pills, with starch, or in solution in distilled water.

Pills of Chloride of Gold. H. of Germ.

Rx. Auri chloruret. gr. x;
Pulv. glycyrrhiz. 3 iij;
Syrup. simplicis, q. s.

Divide in pilulas cc, quarum capiat unam vel duas quotidie.

Each pill contains gr. 1-20th of chloride of gold.

EXTERNALLY. In frictions upon the tongue and the gums, gr. 1-10th— $\frac{1}{2}$ mixed with starch.

Powder of the Chloride of Gold. H. of Italy.

Rx. Auri chloruret. gr. i;
Pulv. amyli, \mathfrak{D} v.

Fiant pulveres, xv.

One of them should be used as a friction.

CHLORIDE OF GOLD AND SODIUM.

This preparation possesses the same properties as the simple chloride; but is more generally used.

INTERNALLY. Gr. 1-20th to 1-10th, in pills.

Antivenereal Pills. H. of Montp.

Rx. Auri et sodæ chloruret. gr. $\frac{1}{2}$;
Extract. saponariæ, 3 i;
Pulv. gum acaciæ, q. s.

Fiant pilulæ xxx, quarum capiat i—viij quotidie.

Each pill contains gr. 1-60th of the chloride.

EXTERNALLY. Gr. 1-15th mixed with starch, in frictions in the interior of the mouth.

Powder of the Chloride of Gold and Sodium.

H. of Montp.

Rx. Chlor. auri et sodii, gr. i;
Pulv. iridis florent. gr. ij.

Misce intime, et divide in chartulas, xv.

One of these powders should be used at each friction.

Pommade of the Chloride of Gold and Sodium. (Magenlie.)

Rx. Chlor. auri et sodii, gr. x;
Adipis præpar. 3 ss.

Fiat unguentum.

This pommade is applied to the surface of a small blister, to cause an absorption of the salt of gold.

OXIDE OF GOLD.

It possesses the same effect as the chloride.

It is employed in complicated cases of scrofula and syphilis.

INTERNALLY. Gr. 1-10th—j, daily.

Pills of the Oxide of Gold. H. of Montp.

Rx. Auri oxidi, gr. vj;
Ext. mezerei, 3 ij.

Divide in pilulas lx, sumat ij—x quotidie.

Each pill contains gr. 1-16th of the oxide of gold.

GOLD.

When brought into an extreme state of division, it acts like the preceding preparations. It is only employed externally by the endermic method, and to excite venereal ulcerations of the palate.

Syrup of Gold. H. of Montp.

Rx. Auri, \mathfrak{D} j;
Syrup. acaciæ, 3 i.

Misce.

Employed in lotions in ulcers of the pharynx, and to cancers, &c.

Pommade of Gold. H. of Montp.

Rx. Auri, 3 i;
Adipis, 3 i.

Fiat unguentum.

Employed in frictions on buboes, and also applied to the surface of blisters.

[When the ulcers shew a tendency to cicatrise, the following ointment is preferred, and also to dress setons, according to M. Magendie, 1835. (*Op. cit.*):—

Rx. Auri et sodii muriat, \mathfrak{D} ss;
Adipis preparat. 3 iv.

THE SALTS OF PLATINA.

These are prepared in the same manner as those of gold, and are said to possess the same properties. M. Magendie does not appear to have employed them; or if he have, he has not mentioned the doses. (*Op. jam. cit.* 1835). T.]

CHLORIDE OF BARIUM.

In large doses it is a violent poison; in smaller ones it appears to be useful in scrofulous diseases, engorgements of the viscera and lymphatic glands, scirrhus affections, dropsies, &c. It is also used as an anthelmintic. It is not much employed at the present day, and its administration requires the greatest caution, on account of its poisonous effects. It is sometimes used as an excitant and a feeble escharotic in lotions on scrofulous ulcers.

INTERNALLY. Gr. $\frac{1}{4}$ — $\frac{1}{2}$, in a mucilaginous vehicle.

Solution de Muriate de Baryte. P. (Muriate of baryta, 1 part; distilled water, 5 parts.) Gutt. ij—x, in a mucilaginous potion.

Antiscrofulous Solution. H. of Germany.

Rx. Chlor. barii,
Ferri hydrochlor. $\mathfrak{a}\mathfrak{a}$ 3 ss;
Aq. destill. 3 i.

Fiat solutio.

Dentur gutt. xx—lx pro dosi. In a mucilaginous vehicle.

Each drachm contains gr. ivss of the chloride.

Antiscrofulous Pills. H. of Italy.

Rx. Barii chlor. gr. i;
Extract conii, gr. ij;
Succi sambuci, q. s.

Fiant pilulæ iv, quarum sumatur una sexiâ quaque horâ.

EXTERNALLY. Solutions. In lotions on scrofulous ulcers.

Resolvent Drops. H. of Germ.

Rx. Barii chlor. gr. xij;
Aq. destillatæ, ℥ ij.

Fiat solutio.

A few drops to be injected into the eye, in pearl or opacity of the cornea.

HYDROCHLORATE OF LIME.

Its mode of action resembles that of the muriate of barium, only that it is not poisonous—it should be preferred to that medicine; nevertheless it is not much used. It is employed in scrofulous affections and swelling of the lymphatic glands. In large doses it is a purgative.

INTERNALLY. Gr. vi—3 i, dissolved in water.

Solution of Muriate of Lime. H. of London.

Rx. Calcis muriat. ℥ ij;
Aq. destillatæ, ℥ iij.

Calcis muriatem in aquâ liqua tum per chartam cola. Guttæ xxx—3 i sumantur, e cyatho aquæ cum saccharo.

CHAPTER IX.

MEDICINES WHICH ARE USED AS EXCITANTS OF THE NERVOUS SYSTEM.

NUX VOMICA.

IN large doses this is a most violent narcotico-acrid poison; in small ones it is an energetic stimulant of the nervous system: its principal action is on the spinal marrow, and it excites spasmodic contractions of the muscles. It is administered internally in the treatment of paralysis which does not depend on cerebral lesion or disorganization, in contraction and atrophy of the extremities or limbs, in certain cases of amaurosis, incontinence of urine, &c. Its administration requires the greatest precaution.

INTERNALLY. Powder. Gr. iv—xij, progressively, in pills.

Extrait alcoolique. P. Gr. ½—iv, in pills. The dose may be gradually increased to gr. x—xv.

Tincture. Gutt. v, gradually increased to xxx, in a potion.

Alcool. de Noix Vomique. F. de M. (Extract of nux vomica, gr. iv; alcohol (36°), ℥ i.) Gutt. xx—xxx, and more.

It is used externally in paralysis and atrophy.

Powder of Nux Vomica. H. of Germ.

Rx. Pulv. nucis vomic. gr. iij;
Gummi acaciæ,
Sacchari, āā, gr. xij;

Divide in chartulas sex, quarum sumat ij—vj quotidie.

Pills of Nux Vomica.

Rx. Extract nucis vomic. alcohol. ℥ ss;
Confect. rosæ gallic. ℥ ij.

Fiant pilulæ xxxvj, quarum sumat unam quotidie.

The dose should be gradually increased.

Stimulating Pills. H. of Italy.

Rx. Pulv. nucis vomicæ, gr. xxx;
Conf. rosæ gallicæ, q. s.

Divide in pilulas x, capiat ij in die.

Solution of the Extract of Nux Vomica. H. of Germ.

Rx. Extract. nucis vomicæ, gr. x;
Mucilag. acaciæ, ℥ i;
Aquæ puræ, ℥ vi.

Sit solutio.

Dosis cochleare magnum secundâ quaque horâ, ex ℥ i, syrupi acaciæ vel aquæ hordei.

EXTERNALLY. Tincture. P. In frictions on parts affected with paralysis.

Liniment of Nux Vomica. (Magendie.)

Rx. Spirit nucis vomic. ℥ j;
Liquoris ammoniæ, ℥ ij.

Misce.

This was employed with good effects, and also in the malignant or blue cholera of Paris, 1832.

ALCOHOLIC EXTRACT OF NUX VOMICA.

It is used in all cases of debility, whether general or local; in amaurosis with paralysis of the eyelid (M. Edwards); with the best effects in debility of the genital organs, incontinence of urine, &c.; indigestion, partial atrophy of the superior and inferior extremities (Magendie, Formulaire pour la Preparation et l'Emploi de Plusieurs Nouveaux Medicaments, &c., 1835). It should not be given in paralysis succeeding apoplexy or cerebral hæmorrhage. It was given to an infant aged three years and a half, affected with hemiplegia after measles, with success: dose, half a grain every four hours. In paralysis of the arm, the dose was increased, during fifteen days, to thirty grains three times a-day (Gendr. Journ. Gen. de Med., 1824); in St. Vitus's dance, after all means had failed (M. Cazanave). The best mode of exhibiting it is in pills: dose, half a grain twice a day, gradually increased. Its effects are tremblings and tetanic spasms.

STRYCHNINE.

The active principle of nux vomica, acting consequently in the same manner, but with more energy. It is employed in the same cases. It is an alkali.

[This medicine possesses the most extraordinary influence on the brain, spinal marrow, and ganglionic systems, or, to speak scientifically, on the cerebro-spinal and ganglionic system (sympathetic system). I have not only employed it in paralysis and nervous disorders in all parts of the body; but in a host of maladies of Protean form which are referable to disordered innervation. I am in the habit of using it daily in all the forms of hysteria, in chorea, nervous apo-

plexus, hypochondriasis, neuralgiae, spinal irritation, hemicrania, hemiplegia, paraplegia, and partial paralysis; and the patients under my care are examined by several intelligent students, some of whom were in practice. I have also used it successfully in diarrhoea with rice-coloured dejections, and accompanied by blueness of the extremities, in dysentery, colic, and other spasmodic disorders. I order it daily in cases of hysteria, dyspepsia, &c., in the dose of 1-12th of a grain, morning and evening. It causes a degree of warmth in the stomach, and rapidly relieves the sense of sinking at the epigastrium, so troublesome to dyspeptic and nervous persons. It possesses great power on the sympathetic or ganglionic, as well as on the cerebro-spinal system, and thence relieves disordered nervous function in all parts of the body. I seldom exceed 5-12ths of a grain daily, as I have tried the medicine in a vast number of cases, and few persons will bear a larger dose. T.]

INTERNALLY. *Powder.* Gr. 1-12th—1-18th, in pills.

Alcool de Strychnine. F. de M. (Strychnine, gr. iij; alcohol, ʒ i). Gutt. vj—xxiv, in a potion.

Powder of Strychnine. H. of Italy.

Rx. Strychninae, gr. i;
Oxydi ferri nigri, ʒ i;
Sacchari, ʒ iij.

Divide in chartulas vj, quarum sumat unam mane nocteque.

Pills of Strychnine. (Magendie.)

Rx. Strychninae, gr. ij;
Conf. rosae gall., ʒ ss.

Misce. et divide in pilulas xxiv, ex quibus capiat unam mane nocteque.

Pills of Strychnine. (Ryan.)

Rx. Strychninae, gr. i;
Confect. rosae, ʒ ss;
Pulv. glycyrrhiz. ʒ ss.

In pilulas xij divide, quarum capiat unam mane nocteque, et augeatur dosis ad iv vel v quotidie.

It is necessary to regulate the bowels previous to the exhibition of strychnine, which is a powerful astringent. I have repeatedly known a few of the preceding pills check a profuse diarrhoea with rice-coloured dejections, and even when the extremities were blue in malignant cholera.

Potion with Strychnine. (Magendie.)

Rx. Strychninae, gr. i;
Sacchari, ʒ iij;
Acid acetic. gutt. ij;
Aq. destillatæ, ʒ ij.

Fiat potio, cujus capiat cochleare min. mane nocteque.

The dose should be gradually augmented to three or four spoonful.

EXTERNALLY. Gr. 1-12th— $\frac{1}{2}$, applied on the surface of a small blister placed on the temple or eyebrow in amaurosis. The me-

dicine has been also used endermically in paralysis and atrophy.

Test for Strychnine.—Good strychnine will not be reddened by nitric acid.

SULPHATE OF STRYCHNINE.

Its action is the same as that of strychnine, but more energetic, on account of its great solubility. It is sometimes had recourse to in diseases which have resisted the action of strychnine.

INTERNALLY. *Powder.* Gr. 1-20th—1-12th, in pills, with q. s. of the confection of red roses, or in a draught.

BRUCINE.

The active principle of false angustura; it acts on the system in the manner of strychnine, but less powerfully. It has been employed with advantage in certain cases of paralysis, in atrophy of the limbs, and in some analogous cases.

[According to Andral, six grains are equal to one of strychnine. T.]

INTERNALLY. *Powder.* Gr. $\frac{1}{4}$ —vj, progressively.

Alcool de Brucine. F. de M. (Brucine, gr. xvij; alcohol (36°), ʒ j). Gutt. vj—xxiv, in a potion.

Pills of Brucine. (Magendie.)

Rx. Pulv. brucinae, gr. xij;
Confectio. rosae, ʒ ss.

Divide in pilulas xxiv, ex quibus capiat ij quotidie.

The dose may be progressively increased to six in the day.

Stimulating Potion. (Magendie.)

Rx. Brucinae, gr. vj;
Aq. destill. ʒ iv;
Sacchari, ʒ ij.

Fiat mistura de qua cochleare magnum sumatur mane nocteque.

[The sulphate, hydrochlorate, phosphate, oxalate and nitrate of brucine are not employed medicinally. T.]

PHOSPHORUS.

Phosphorus is one of the most energetic poisons. When used in extremely small doses, it is a powerful excitant of the nervous system, and appears to act likewise on the organs of generation. It is recommended in typhoid fevers accompanied with excessive adynamia, in certain cases of paralysis, gout, obstinate rheumatism, &c. It is a dangerous medicine, and requires the most serious attention when employed.

INTERNALLY. Gr. $\frac{1}{8}$ —i daily, in an emulsion.

Ether Phosphorée. P. (ʒ i contains about gr. $\frac{1}{2}$ of phosphorus). Gutt v—x in an emulsive potion, may be gradually increased.

Phosphorated Oil.

Huile Phosphorée. F. de M. (Phosphorus, ʒ j; oil of sweet almonds ʒ ij; after the phosphorus is perfectly dissolved, decant,

and add q. s. of the essential oil of bergamot). Gutt xx—xxx in an emulsive potion, a spoonful to be taken for a dose. Each drachm contains gr. 4½ of phosphorus. (March 1835). See APHERODISIACS.

EXTERNALLY.

Pommade Phosphorée. P. In frictions, but with the greatest care. (Phosphorus two parts, adeps and aqua, āā 100 ol. lavend. q. s.).

PHOSPHORIC ACID.

[Dr. Lentin of Gottingen applied a lotion composed of one part of phosphoric acid, and eight of distilled water twice a day, to ulcers caused by caries of the bone. (Magen-die's Formulary 1835. T.)]

ARNICA. (FLOWERS AND ROOT.)

A very active stimulant to the nervous system. It is used in chronic rheumatism, paralysis, and amaurosis. It is also recommended as a febrifuge. The flowers pulverized act powerfully.

Subst. Incompat. The sulphates of iron and zinc, the acetate of lead, the mineral acids, &c.

INTERNALLY. Flowers. Powder, gr. vj—x and gradually increased xxx—vj.

Decoction and Infusion, 3j—iv to Oij of water. They should be filtered through paper.

The root. Powder, gr. xij—3i.

Decoction. The same as the flowers.

Tincture éthérée. P. ʒi—3ss in a potion.

Infusion of Arnica. Hot. D. H. de la Ch.

Rx. Florum arnicæ montanæ, 3j;

Aquæ ferventis, Oij.

Cola per chartam.

A teaspoonful to be taken at a time and frequently repeated. An ounce of the syrup of orange peel may be added to this infusion. It is employed in certain cases of apoplexy, paralysis, &c.

Infusion Nervine d'Arnica. H. of Italy.

Rx. Radicis arnicæ mont. 3ij;

Aquæ ferventis, q. s.

Coque ad, 3vj, per chartam cola et adde, Etheris sulphurici, ʒij.

The dose is a spoonful at a time.

Vinous Infusion of Arnica. H. of Germ.

Rx. Flor. arnic. mont. 3ss;

Aquæ puræ,

Vini albi, āā 3vj.

Coque, cola, et adde,

Syrup. cort. aurant, 3ss.

Misce.

The dose is half a glassful every hour.

Compound powder of Arnica. H. of Germ.

Rx. Pulv. rad. arnicæ,
——— serpent.

Olei menth. piper. āā 3ij.

Divide in chartulas vj, quarum capiat unam, secundā quāque horā.

In severe fevers accompanied with diarrhæa.

VOL. VII.

Stimulating and Tonic Bolus. H. de Montp.

Rx. Pulv. flor. arnicæ,

Camphoræ, āā gr. iv;

Theriaceæ, q. s.

Fiat bolus.

EXTERNALLY. *Decoction.* In lotions, fomentations, &c.

ALCOHOL.

Alcohol is one of the most energetic diffusible stimulants. It acts, when concentrated, as a violent poison; when diluted, and in small doses, it causes a general stimulation; in large doses, it produces ebriety and may occasion death. Alcohol at 36° or rectified spirit of wine, is used in preparing tinctures, &c. It is never employed alone as medicine. Diluted with water, it is used as a tonic and stimulant in diseases accompanied with adynamic symptoms, typhus, convalescence after serious illness, delirium tremens, &c. It is used externally, concentrated, as a rubefacient; and when diluted with water as an astringent, tonic, and refrigerant, in many circumstances.

INTERNALLY. 3j—3ij diluted, in drinks.

Punch. H. des Enf.

Rx. Spirit. rectificati, 3ij;

Tincturæ melissæ, 3ij;

Syrupi simplicis, 3j;

Potion. acaciæ, 3ij.

Misce.

Given in smaller quantities to children of a debilitated habit, and in dangerous fevers, in convalescence after long and severe illness, &c.

Alcoholized Lemonade. Hot. D.

Rx. Alcoholis,

Mellis, āā 3i;

Syrupi tartarici, 3ij;

Aquæ, Oij.

Misce.

Employed in the same cases as the preceding preparation.

Stimulating Drinks. H. of Germ.

Rx. Alcohol. 3ias;

Inf. cort. aurant. Oij.

Misce.

A small cupful at a dose.

EXTERNALLY.

In frictions, lotions, and fomentations, as excitants and stimulants.

Astringent Lotion.

Rx. Alcohol. 3ij;

Aquæ calcis, Oss.

Fiat lotio.

WINE.

Astringent wines act as tonics as well as excitants; sparkling wines, whose actions are carried to the brain, and which are very quick in taking effect, exercise, notwithstanding the small portion of alcohol they contain, a marked diuretic influence.

Wine is administered with advantage in

certain cases of adynamic and ataxic fevers, in scrofulous and scorbutic affections, and in all asthenic diseases. It also serves as a vehicle for many medicines, and enters into the composition of a great many official preparations.

[Diluted with water and sweetened, it is of great value in diseases of infants attended with much prostration of strength, and also as a vehicle for quinine. T.]

INTERNALLY. Diluted with water, with or without sugar, as a drink in certain fevers accompanied with adynamia.

[Wine whey was an old remedy in such cases. T.]

Pure, a spoonful at a dose, in convalescence after serious illness.

Alcoholized Vinous Lemonade. Hot. D.

Rx. Vini albi,
Aque, ā ā Oj;
Alcohol, ʒ i;
Syrup. tartar. ʒ ij.

Misce.

Taken as a drink in certain atonic affections, &c.

EXTERNALLY. In lotions, fomentations, local baths, &c.

Vinous Fomentation. Hot. D.

Rx. Ros. gall. petal. ʒ i;
Vini rubri, Oj.

Decoque et cola.

It is frequently applied to certain indolent ulcers.

Vinous Fomentation of Sage. H. de la Ch.

Rx. Vini rubri, Oj.
Foliorum salviæ, ʒ i.

Decoque et cola.

It is used in the same manner as the preceding one.

The Fomentation Vineuse Alcoolique, of the same hospital, is made by adding ʒ viij of camphorated alcohol, and in replacing the leaves of sage by an equal quantity of juniper berries, the Fomentation Vineuse de Baies de Genievre, of la Char., is formed.

Vinous Lotion. H. des Enf.

Rx. Vini, Oj;
Mellis, ʒ ii.

Fiat lotio.

Applied to wounds and ulcers of an unhealthy aspect.

Irritating Injection. H. de Paria.

Rx. Vini fervent. Oij;
Alcohol. q. s.

Employed in the operation of hydrocele by injections, in cases of large openings of the integuments by chronic abscesses.

CHAPTER X.

MEDICINES EMPLOYED IN GENERAL AS ANTISPASMODICS.

SULPHURIC ETHER.

In large doses it irritates the stomach extremely, and at the same time produces a

kind of ebriety. In small ones, it acts on the nervous system, sometimes as a sedative, at others as a lively stimulant, but always in a transient manner. It is employed with advantage in the generality of nervous affections, such as spasmodic vomiting, nervous colics, hysteria, asthma, and, in general, all neuroses, typhoid fevers, to calm convulsive movements, hiccup, &c. It is frequently used to combat ebriety, and is recommended as a febrifuge and anthelmintic. It is often very useful, in enemata in nephritic colic. Its vapour is employed to irritate the pituitary surface in cases of syncope, and may prove very useful in certain nervous affections of the respiratory organs. Externally it serves as a refrigerant in certain cases of neuralgia, megrim, &c. In fine, this liquid is employed as a solvent for a great number of medicines.

INTERNALLY. Gutt. vi—x with sugar, or xx—ʒ ss in a potion.

Potion Antispasmodic. P. A spoonful at a dose.

[Sulphur. ether, ʒ j; orange-flower water, ʒ iv—syrup, ʒ j.]

Ether sulfurique Alcoolisé, or Liqueur Anodyne D'Hoffman, gutt. x—ʒ j, in a potion.

Sirap d'Ether. P. ʒ ss—i, in sedative and antispasmodic potions.

Potion Gommeuse Etherée. H. de la Ch.

Rx. Ether. sulphur. gutt. xvij;
Potionis gummi, ʒ iv.

Fiat potio, cujus capiat cochleare magnum pro dosi.

Potion with Mint Water. H. St. Ant.

Rx. Ether. sulphur., ʒ ss;
Aque menthæ, ʒ iv;
Syrup. simpl. ʒ ss.

Misce. Dosis coch. magnum.

Antispasmodic Potion. Hot. D.

Rx. Etheris gutt. xxx;
Infusi tiliaë,
—— flor. aurant, ā ā ʒ i;
Aq. destill. menthæ,
Aque destill. melissæ,
—— flor. aurant, ā ā ʒ j;
Syrup. simplicis, ʒ i.

Misce. Dosis cochleare magnum.

The Antispasmodic Potion, of the H. St. Ant., does not contain the distilled waters, and the ether is replaced by ʒ ss of alcoholized sulphuric ether.

The *Potion Calmant*, of the H. des Ven., is similar to the preceding one. It is composed of the gutt. xv of the anodyne liquor of Hoffman, and the same quantity of laudanum to ʒ v of the infusion of tilia and ʒ iij of orange flower water.

The *Potion Antihysterique*, of the same hospital, differs from the preceding by the addition of alcoholate of amber, and of castor, ā ā gutt. xv. It is employed in nervous affections accompanied by severe pains or convulsions.

The *Potion Antispasmodique*, of the H. des

Enf., is almost the same as the *Potion Calmant des Ven.*, except that it does not contain the laudanum; and the liquor of Hoffman is replaced by 3 ss of sulphuric ether.

NITROUS ETHER.

It possesses the same properties, and is used in the same cases as sulphuric ether; it appears to act also as a diuretic. It is employed in some diseases of the liver.

INTERNALLY. Gutt. xx—xxx, in a potion.

Ether Nitrique Alcoolisé. P. Gutt. xxx, and even more, in a potion, as a diuretic.

Acidulated Julep. H. of Germ.

Rx. Etheris nitrici, ℥i;
Decocti hordei, ℥xxiv;
Syrup. limon. ℥ij.

Misce.

A small cupful at a dose.

Sedative Emulsion. H. of Montp.

Rx. Ether. nitr. cum alcohol. gutt. xxiv;

Emulsion. sem. melonis, ℥iv;
Syrup. nymphaeae alb. ℥i.

Fiat emulsio, cujus sumatur coch. mag. pro dosi.

In gonorrhœa.

EXTERNALLY. *In frictions*, as a refrigerant. Any quantity.

Antiphlogistic Gargle. H. of Germ.

Rx. Etheris nitrici, ℥ss;
Decocti althææ, Oij;
Syrupi ejusdem, ℥ij.

Misce.

HYDROCHLORIC ETHER.

It possesses the same properties, and may be used in the same case cases, as the preceding preparations. It is not much employed.

INTERNALLY. Gutt. xx—xxx, and even more, in a potion.

Ether hydrochlorique Alcoolisé. P. Gutt. xx—3 ss, in a potion.

ACETIC ETHER.

It has the same properties, and may be employed in the same manner as the preceding. It is not much used except externally, in frictions on those parts affected with rheumatism and neuralgia.

INTERNALLY. Gutt. 3 ss, in a potion.

EXTERNALLY. Gutt. 3 ij—iv, in frictions.

SUBNITRATE OF BISMUTH.

In doses of a drachm, an irritant poison; in small doses a very efficacious sedative in neuralgia of the stomach and intestinal canal, according to MM. Odier, Delaroche, Clarke, Lombard, Trousseau, &c. It is employed with great success in gastralgia, pyrosis, gastro-enteralgia, chronic gastritis, chronic diarrhœa, spasmodic cholera, to calm the cramps of the stomach, and to subdue the spasmodic diarrhœa and vomiting.

INTERNALLY. Gr. x—xx, and even 3j, in twenty-four hours, in pills, or in a mucilaginous vehicle.

Sedative Powder. H. Dieu.

Rx. Bismuth. subnit. gr. iv;
Magnesiæ calcin.,
Sacchari purif., ā ā gr. xl.

In chartulas iv divide, capiat j, singulis horis.

Tonic Pills. H. of Amer.

Rx. Bismuth. subnit. ℥ij;
Mucilag. acaciæ, q. s.

Fiant pilulæ xxxvj. Dosis j, secundis horis.

In dyspepsia.

CAMPHOR.

In small doses it acts as a sedative; in large ones it is a very energetic excitant, which causes very violent nervous symptoms, and may even occasion death. It is employed internally in nervous and spasmodic affections, such as neuralgia, spasms of the bladder and œsophagus, hysteria, chorea, &c. It is also used in typhoid fevers, to combat nervous symptoms, and especially delirium, subsultus of the tendons, &c. It is strongly recommended as an antiaphrodisiac.

[It is said to facilitate the action of mercury. (See *Mercury.*) T.]

It is used externally with much advantage in rheumatic pains, gout, neuralgia, &c. It is a medicine which is very much employed.

INTERNALLY. Gr. ij—℥i, and even 3 ss or 3 i daily, in pills, or suspended in a vehicle by the aid of the yolk of an egg or of a mucilage.

Potion camphrée. P. The dose is a spoonful at a time.

Camphorated Powders. H. of Germ.

Rx. Camphoræ,
Acid. benzoic, ā ā gr. vi;
Sacchari, 3i.

Divide in chartulas vi, quarum capiat unam tertiâ quâque horâ.

Camphorated Boluses. H. of England.

Rx. Camphoræ,
Conf. rosæ, ā ā 3i.

Fiant boli xij, e quibus sumatur una quartâ vel sextâ quâque horâ.

Boluses of Camphor and Nitre. H. Militaires.

Rx. Pulv. camphoræ,
Potass. nitratis, ā ā ℥i;
Confect. rosæ, q. s.

Divide in bolos vi quarum sumat, iv—vi quotidie.

In typhous fevers.

In the *Bols Camphrés* of the Hot. D., the confection of roses is replaced by starch and syrup.

In the *Pilules Antiseptiques* of the H. St. Ant., the starch is replaced by gum acaciæ: the above quantity is divided into xvij pills, iv—xii daily.

The *Bols Camphrés et Nitrés* of the H. de la Mat. contain only gr. viii of camphor and vi of nitre, united by q. s. of the yolk of an egg.

Boluses of Camphor and the Hydro-sulphate of Antimony. H. de la Mat.

Rx. Camphoræ, ℥i;
Antim. dydro-sulph. gr i;
Potass. tart. gr. xvi;
Vitelli ovi, q. s.

Divide in bolos iv.

Used in certain fevers accompanied with prostration of strength.

Sedative Pills. Hot. D.

Rx. Camphoræ, gr. xij;
Hydrargyri submur. gr. vi;
Syrupi simplicis, q. s.

Fiant pilulæ iv.

Antispasmodic Pills. Hot. D.

Rx. Camphoræ, gr. vi;
Extracti opii, gr. j;
Nitratis potassæ, gr. iv;
Syrupi simplicis, q. s.

Divide in pilulas vi.

Pills used in Hospital Gangrene. Hot. D.

Rx. Camphoræ, ℥i;
Moschi, gr. viij;
Ext. opii, gr. ij;
Syrup simpl. q. s.

Fiant pilulæ viij.

Each pill contains gr. iij of camphor.

Antiseptic Potion. Hot. D.

Rx. Camphoræ, gr. x;
Decoct. cinchon. ℥iv;
Tinct. cinnam. ℥i;
Ammoniaæ acet. ā ā ℥i;
Syrup. simplic. ℥i.

Fiat potio, cujus sumatur cochl. mag. pro dosi.

In Fevers accompanied with adynamia.

Emulsion of Camphor with Nitre. H. of Germ.

Rx. Camphoræ,
Potass. nitrat., ā ā gr. xv;
Vitelli ovi, q. s.

Tere et adde,

Aquæ tilia, ℥iij.

Fiat emulsio, cujus cochl. magnum sumatur pro dosi.

Employed to diminish painful erections in acute urethritis.

The *Potion Camphrée*, of the Hot. D., differs from the preceding in the dose of the camphor and nitre being raised to ℥i, in the yolk of the egg being replaced by acacia gum, and in the vehicle being ℥v of the pectoral infusion, sweetened with ℥i of the syrup of capillaire. It is administered in the same cases.

Camphorated Potion with Ether. H. of Germ.

Rx. Camphoræ, ℥i;
Ether. sulph. ℥ij;
Liq. opii (Sydenham), gutt. xx;
Aquæ cinnam. ℥vi.

Fiat potio, cujus capiat cochleare magnum tertiâ vel quartâ quaque horâ.

Camphorated Water with Ether.

Rx. Camphoræ,
Ether. sulph. ā ā ℥i;
Aquæ, ℥vii.

Dissolve the camphor in the ether, and then pour the solution into a vessel containing the water. This vessel ought to have a tube and a small cock at its base, and the neck should be furnished with a straight tube, enveloped in a piece of lint. The dose of this liquor is a spoonful, with syrup in nervous affections.

Camphor Mixture. H. of England.

Rx. Camphoræ, ℥i;
Spirit. rectific. gutt. x;
Sacchari, ℥ss;
Aquæ, Oj.

Triturate the camphor with the spirit, and then with the sugar; add the water, and strain.

The dose is ℥j—ij every three or four hours.

It is often used as a vehicle for other medicines.

[The addition of magnesia, according to the Dublin pharmacopœia is a great improvement. T.]

EXTERNALLY. *Alcohol Camphré.* P. In lotions, fomentations, &c.

Liniment Camphré. P. q. v. In frictions.

Baume Opodeldock. P. In frictions on those parts affected with rheumatism.

Enema of Camphor. H. de la Mat.

Rx. Camphoræ, ℥ij;
Vitelli ovi, No. 1;
Decocti hordei, Oij.

Misce pro enema.

Employed in fevers accompanied with adynamia, and as a sedative in painful neuralgia, &c.

Lavement Antiseptique. H. Dieu.

Rx. Camphoræ, ℥ij;
Cinchonæ, ℥i;
Aquæ, Oij.

Misce.

Employed in fevers in which there is a tendency to gangrene.

Camphorated Gargle. H. of Italy.

Rx. Camphoræ, ℥i;
Ether sulph., ℥i;
Syrup. simplic., ℥i;
Aquæ, Oij.

Fiat gargarisma.

Used in maglignant angina.

Camphorated Vinegar. H. Militaires.

Rx. Camphoræ, ℥i;
Acet. fort., ℥viij.

Liqua.

Employed in lotions, Frictions, &c.

Camphorated Fomentation. H. of Germ.

Rx. Camphoræ, ℥iv;
Acid acetic, ℥ij;
Aceti, ℥x.

Fiat lotus.

Employed in fomentations to parts threatened with gangrene.

Lotion of Elder with Camphorated Alcohol.
H. des Enf.
℞. Spirit. rect. cum camph. ʒ ij;
Infusi flor. sambuci, Oj.
Fiat lotio.
Employed in the treatment of indolent glandular swellings, in children of a scrofulous habit.
(To be continued).

—o—
Reviews.

An Exposition of the Nature, Treatment, and Prevention of continued Fever. By Henry M'Cormac, MD. 8vo. pp. 202. London: Longman & Co. 1835.

ON a former occasion we gave a brief notice of this work, and now redeem our promise to place its merits before our readers. The subject of it has occupied the attention of our profession from the earliest period of medical history; and though a vast deal has been written upon it in all ages, its real nature is still unknown. The author of the volume before us has quoted a great number of ancient and modern writers on fever, and placed their views in a perspicuous order before his readers. He has also added the result of his own experience, and given the fullest account of the disease, hitherto published in our language. He has, however, been guilty of a serious omission in having neglected a proper arrangement of his matter, and published the whole, without any order, or even a table of contents to guide the reader. His work is one chapter: the etiology, pathology, and treatment of fever are only to be discovered by perusing the whole volume; and this is what few can accomplish, at least those who are actively engaged in practice. This is a matter of regret, as in all other respects, the work comprises the views of the most renowned writers of many centuries; and it is really astonishing that the author could have condensed such a fund of information within so small a compass. The want of arrangement of the contents precludes the possibility of our attempt to analyze, while the nature of the subject, and the limits by which we are circumscribed, remind us that we could not occupy several numbers with extracts, to the exclusion of much more practical and valuable matter to the bulk of our readers. The weekly medical periodicals cannot give long reviews, unless of works containing a variety of practical information. They can only notice the majority of productions of this description.

We have, however, said enough of this work to induce our readers to peruse and possess it; and we trust its author will, in the next edition, give an index or table of contents, and arrange his matter in separate sections.

As a compilation, this work is unequalled in our literature, and well deserves a place in every medical library. It comprises the doctrines and opinions of the best writers on fever, of this and other countries.

—o—

The Practice in the Liverpool Ophthalmic Infirmary for the Year 1834; being the First Special Report. By Hugh Neill, Surgeon to the Charity. 8vo. pp. 55. A Plate. London: Longman and Co. 1835.

WE highly approve of the laudable example set by the author in publishing an annual report of the diseases treated at a provincial public charity. Such a proceeding is not only valuable to the governors, but also to the cause of science. Many are too lazy, indolent, or incompetent to perform the task of arranging materials for a clinical report, while others are deterred from the attempt by the fear of criticism.

Mr. Neill, in a prefatory address to the governors, ably and properly contends, that the publication of a clinical report is legitimate, that publicity is essential to the full development of a charity, and that there is a moral as well as professional necessity for making public the practical results in such an institution. We fully agree to all these sentiments. He is also justified in arguing in favour of the advantages which accrue from the subdivision of labour in the arts and sciences. We hold, however, that every medical practitioner should be deeply versed in all diseases, and practise in those he pleases, or to which his inclination leads him. The mere oculist, aurist, dentist, &c., would be a bad, dangerous, and ignorant practitioner; and fortunately for humanity and science, few such incompetent persons now exist amongst us. All rising medical men study every form of human infirmity; but prefer a certain branch of our science.

After having disposed of the preceding general observations, our author gives a tabular view of the diseases of the eye, which fell under his treatment in 1834, with a

history of some of these, which proves him to be a scientific surgeon, and an excellent operator. His explanation of the operations for cataract is good; while his narrative of cases of blindness cured by operation, must not only be highly gratifying to himself, as well as to the governors of the Liverpool Ophthalmic Infirmary, but to the public. We hope to see a continuation of clinical reports from this institution, and others from the many charitable establishments in the great town of Liverpool. We are delighted at the brilliant prospects of our brethren in that quarter; and we trust, ere long, not only to have the pleasure of recording the establishment of a medical institution, but of one or more medical schools in Lancashire.

—o—

An Inquiry into the Nature and Causes of Lateral Deformity of the Spine; in Reference, more especially, to the pernicious effects of certain Moral and Physical Influences, resulting from the modern system of Female Education. By Edward W. Duffin, MD. 8vo. pp. 94. London: 1835.

WE have expatiated so much on the subject of spinal deformities in our last number, that to re-enter upon it, would be a work of supererogation. We have touched on many causes of spinal deformities omitted by our author, comprised all the topics in his work, and given a much fuller account of the treatment.

He directs his attention to three parts of female education—dress, studies, and amusements. We find nothing unnoticed by us under these heads; and consequently cannot again comment upon them. In making this statement, we by no means intend or wish to insinuate, that there is not much instructive matter in the essay before us, especially to those who have not perused other tracts, works, or lectures on the same subject. But we must observe, that the author might have dilated to a greater extent than he has done, more particularly in a tract better suited for the general than the medical reader. He has, however, written enough to convince those engaged in the business of education, of the formidable evils of tight lacing, the erect attitude for six or twelve hours at one time, and the objectionable amusements allowed female children.

This essay would be of immense good, if perused by parents, or those engaged in the superintendence of scholastic pursuits.

—o—

A Treatise on the Causes and Treatment of Ulcerous Diseases of the Leg. By — Spender. London: Longman. pp. 210.

THERE is perhaps no department of surgery less tempting to practical investigation than the causes and treatment of ulcers of the legs, and yet, estimating the importance of disease by the number of its victims and the inconvenience it involves, there is scarcely one which so urgently demands the attention of the practitioner as the prevention and treatment of ulcerated extremities. The fact that the author of the volume before us has himself treated about 1000 cases, and that more than 1500* annually present themselves at the central Bureau of Paris, are sufficient proofs of their universal importance, while the portion of our population peculiarly affected, with the nature of the treatment, the disgust it too frequently occasions, and the serious inconvenience arising from this class of patients to our public hospitals, render all efforts tending to mitigate or remove these evils deserving of approbation, and, if supported by the evidence of facts, entitled to our most serious attention.

Mr. Spender, from a review of 1000 cases, thinks himself justified in stating that the greatly preponderating cause of ulcers in the lower extremities is a varicose state of the veins, which precedes the ulceration, and without the presence of which the great majority of ulcers would not exist. This condition of the venous system has not been overlooked by authors on the subject of ulcers, but by none has it been given the prominent place assigned it by Mr. S.; and in no treatise that we are aware of has it more than partially influenced either the classification or treatment. It has been generally described as a result of the ulcer, or an accidental complication, and by all as a condition acting unfavourably on our prognosis, protracting the treatment and increasing the liability to a recurrence of the disease. It has also been viewed as almost confined to a particular vein, and the effects on the larger branches have principally arrested attention. Mr. S., on the other hand, thinks that the varicose veins almost invariably precede the ulceration, that they are by no means limited to the larger vessels, or to the part of the limb where the ulceration occurs, that it is on this positive and defined condition of the structure of the leg that the majority of ulcers depend, that the presence or absence of varicose veins forms the only safe grounds of classification, while

* 2 An. d'Hyg. les Publique. Dec. 1830. Parent du Chatelet, on the causes of ulcerated extremities.

It is the leading indication for our remedial measures.

We do not intend at present occupying our time in discussing the cause of this condition of the veins, feeling satisfied that the materials necessary to arrive at any satisfactory conclusions are not yet in our possession: we have hitherto been too easily satisfied by ascribing it to the position of the legs, and the obstacles thus opposed to the venous circulation, forgetting that these are natural conditions, and consequently provided for in the structure of the parts, while at the same time we must not forget that disease may arise from the abuse of a natural condition, (as too long standing, &c.) as well as from causes foreign to the normal functions of our organs. M. Parent du Chatelet, in a laborious and interesting analysis of 3373 cases, from the incomplete nature of his materials, was unable to arrive at any satisfactory conclusions as to the causes of ulcers in the legs, though he was enabled to deduce the negative results, that neither the vertical position, nor exposure to heat, cold, or moisture, exerted any evident influence either on the production or character of ulcers of the lower extremities. Out of 600 workmen (*débardeurs*) who spend the greater part of every day with their legs immersed in water, he only met with a single example, and that not a severe one. In many occupations involving a standing position ulcerated legs were frequent, but among others subject to the same physical conditions no such liability could be discovered; it is evident therefore that some other aiding or essential condition must be present to which this liability or exemption might be attributed. M. Parent attributes it to the relative exposure to external violence: this is also the opinion of the author, with the essential condition, that ulcerations which follow the action of external causes, depend on an antecedent varicose condition of the veins.

The external characters of ulcers have hitherto invariably, and almost exclusively, formed the basis of their classification, and much ingenuity has been expended in establishing characters for their distinction, and the adjustment of remedies applicable to their varied conditions. The very terms of irritable and indolent include opposite methods of treatment, and the discrimination of the pathological refinements necessary for the diagnosis of particular ulcers, with the selection of appropriate remedies, is frequently difficult and seldom satisfactory.

Whatever simplifies, either in pathology or treatment, facilitates success, and Mr. Spender's views at least possess the merit of being easily understood and easily followed out in practice. There is no constant relation between a cause and a pathological effect, the latter varies with the constitutional peculiarities of each individual, and on the same grounds the external characters of ulcers

may vary, while the essential pathological condition on which they depend may be identical. The author has found that the irritable and indolent, the exuberant and callous ulcers, with all their intermediate varieties, are, in the majority of instances, equally to be traced to a varicose condition of the veins, and that they yield with nearly equal facility to the same remedial measures; he therefore considers their external characters of very secondary importance, directing his treatment almost exclusively against the morbid condition of the vascular system, founding a favourable prognosis on what has hitherto been regarded the great obstacle to success.

He divides ulcers into the varicose and non-varicose, associating this condition with either their local or constitutional peculiarities, as irritable varicose, indolent varicose, venereal varicose, &c., making it at the same time the basis of treatment, not excluding the use of internal remedies, when distinct indications for their administration are present.

The following view of 100 cases contains an average proportion of the varicose and non-varicose ulcers which have fallen under the author's inspection.

79 Varicose; out of these there were 41 simple, 27 very irritable, 11 very indolent.

21 Non Varicose; out of these there were 15 simple, 4 very irritable, 2 very indolent.

	Females.	Males.
Of the whole number	68	32
Of the 79 varicose	59	20
Of the 21 non varicose	9	12

In the second chapter the author discusses with much soundness and ability the general principles of treatment. They are two. 1st. *Imitating a natural process.* 2dly. *Introducing a healthy action.* The natural process of cure for all abraded surfaces is the formation of a scab, by which the healing process is protected until the structure is so far restored that its presence becomes unnecessary: it then falls off. The author seeing no sound reason for our deviating so widely from the process of nature in the treatment of ulcers, while we adhere to it under many other circumstances, directed his attention to the discovery of some artificial application which might imitate in its action the natural scab, or at least facilitate its formation. After numerous trials, and some unsuccessful attempts, he found the desideratum in an ointment composed of lard and prepared chalk, the latter in much larger proportions than what is indicated in our pharmacopœias. It forms a gradual incrustation over the surface of the ulcer, is mild and safe in its application, neutralizes the acrid nature of the discharge, diminishes the necessity for frequent dressings, and in only two or three instances out of several hundred cases failed to give great and immediate relief. The injudiciousness of interfering with the process of cure nature tends to establish, the in-

tility, with few exceptions, of irritating escharotic applications, and the injurious effects of poultices, fomentations, vapours, washings, wipings, spungings, &c., are forcibly animadverted upon. Nature to be conquered must be submitted to, and there is no doubt that we often frustrate the ends we have in view by our numerous and complex remedies. Accomplishing the second indication is of still more importance in the author's estimation than the first, since we may in vain expect any permanent success to follow our local treatment, while the morbid condition on which the disease depends is suffered to remain. As already stated, this condition Mr. S. considers to be a varicose state of the veins. The remedy he proposes is the employment of a powerful and well adjusted compression of the limb. After the treatises of Barton, Underwood, Whately, and others, it would be absurd to bring forward the use of compression in ulcerated extremities as a novelty; the author seems quite aware of this, and simply endeavours to prove that the cases to which it is applicable are far more numerous than has been generally supposed; that its beneficial effects result much more from its general action upon the morbidly modified structures of the limb, than upon the ulcer locally; and in the third chapter, enters minutely into those details necessary to be attended to in its individual application. Many may be disappointed by the absence of striking novelty, and annoyed by the minuteness of the details—but we believe by the practical man, they will be read with interest and advantage. However faulty or vitiated the ulcer may appear, Mr. S. has very rarely recourse to any local or external corrective, but commences by applying the chalk ointment and bandage, a healthy state of the sore soon following the improved condition of the general structures of the limb.

Another important and valuable feature in the treatment proposed by Mr. S. is the avoidance of rest and a horizontal posture, "which have been looked upon," says Mr. Bell, "by almost all practitioners, both ancient and modern, as absolutely necessary for the cure of ulcers in the lower extremities." The inconvenience and often ruin attending confinement to bed among the class of patients most frequently affected, need no comment, and any method by which they may be avoided, possesses on this ground alone powerful claims to our attention. The author feels authorized in saying that "every ulcer (with the single exception where active inflammation exists in the limb) ought to be cured without sending the patient to bed." Rest, according to Mr. S. is positively prejudicial, not only protracting the cure, but greatly increasing the liability to a recurrence of the disease; for it needs no argument to prove that a cicatrix completed while the limb is subjected to its natural motions, presents far greater probability of continu-

ance than one formed under opposite circumstances.

The third chapter is devoted to the particular applications of the principles to individual instances, and contains a clear and practical exposition of the details necessary to be observed by those who would submit the treatment proposed to a fair and unprejudiced trial. The simplicity of the author's treatment will not prove ungrateful at least to the young practitioner; and if he differs with the objections advanced against the more complicated remedies usually employed, he may suspect from the amount of the author's experience, that at least in a great many instances they may be dispensed with.

In cases of the irritable, spungy kind of ulceration, accompanied with great enlargement, and a puffy state of the limb, with an extensive superficial ulceration, and a thin glairy discharge, the treatment proposed appears to have been peculiarly successful. In four cases, one of fourteen, another eight years' duration, the limbs were in a short time reduced to their natural size, the ulcerations were healed, and a healthy state of the skin produced. All had been previously treated by rest, poultices, and fomentations.

Exceptional cases are not overlooked. They are comparatively few in number, and their treatment is rather a modification than an abandonment of the preceding.

In the fourth and last chapter, the question as to the propriety and safety of healing ulcers of the legs is clearly and judiciously discussed. The considerations advanced may tend to remove many of those humoral prejudices which have so frequently obscured this often-debated question.

We have thus as briefly as possible endeavoured to make the reader acquainted with the prominent features of Mr. Spender's little volume, purposely avoiding any speculative considerations as to the truth or fallacy of the general principles it advocates, believing with the author, that they are of secondary importance to the question of—Has the plan been found practically useful? The answer to this is the amount of the author's experience; it is at least as great as that advanced in any other treatise upon the subject, and amply sufficient to entitle the volume to the attention of every practical man. That the treatment differs from that usually enjoined is sufficiently proved by the fact, that ulcerated legs may be found in all our general hospitals, which would not be the case were the author's principles practically enforced. That it differs in many respects from that inculcated in our standard works upon the subject, both in its details and extent of application, every impartial reader will admit; and we would remark that at the present moment our researches in medicine are not so much directed to the discovery of what is unknown as to the successful application of

the knowledge already in our possession; and merit should be tested rather than by the amount of success obtained than by the degree of novelty which may be attached to the means we have employed.

[A review of Mr. Spender's work has appeared in a contemporary journal. We hope it deserves no worse imputation than that of being glaringly partial and superficial. The author apprehends it will not be read by the *scientific* portion of the profession; we believe it will, with the exception of that part of which he is the representative.]

—o—

The London Medical

AND

Surgical Journal.

Saturday, April 11th, 1835.

HOSPITALS SHOULD BE NATIONAL INSTITUTIONS.

IN our last number we pointed out some of the evils which arise from our hospitals being private institutions, and not under the auspices of government. In this country the wealth, generosity, and enterprise, of one or more individuals, has, in many instances, superseded the exertions of the legislature, but without adequately supplying their place: hence our defective hospitals, our joint-stock university, and many other institutions, which, although they reflect credit on the public spirit of their projectors, very poorly supply the place of the grand national foundations which ought to adorn the wealthiest and most powerful country on earth.

All the evils which we lately descanted on will continue to obstruct the progress of medical science among us, till our hospitals are under the protection and control of the legislature—and, we may add, till the medical officers cease to have any connection with them except in their *medical* capacity. It should, we conceive, be an axiom with reference to institutions of this kind, that no doctor should have anything to do with them except to treat the cases, to superintend the medical arrangements, and to instruct the pupils. From the neglect of this precept the greater part of our medical charities have become *doctors' jobs*

—as the public will find out when it comes to know a little more about these matters.

So great a change in the hospital system as that here contemplated, would not be brought about without some difficulty. Possibly, however, those interested in the hospitals now existing might be brought to perceive the expediency of placing them on a broader and more liberal basis; and if not, what is there to hinder the foundation of new hospitals on an improved principle? No doubt it would be attended with some expense, but certainly none worth weighing for a moment against the great public benefits that would arise from it.

The past history of this country has afforded ample proof that we can squander millions to prosecute an unjust war, or execute a foolish treaty; and there is present evidence that a great deal of money may be spent to build a palace little fit for the abode of royalty: surely then to found a few hospitals, and place them on the same footing as those in other civilized countries, would not occasion any very unreasonable demand on the public purse. These notions of ours may be considered by many as extremely wild, but like some other alleged extravagances they will inevitably become matters of fact in the progress of national improvement. To those who regard some of our views as chimerical, we would just suggest, by way of answer, that what is *done* in France or Prussia cannot be *impossible* in England.

We would seriously recommend this subject to the attention of the legislature and the profession, at a time when an improved era of medicine seems to be dawning on us; and we repeat our conviction, that no system of medical legislation will be either beneficial or permanent, without the existence of national hospitals. How far the institutions now in being may be made the basis of such hospitals, we cannot pretend to determine.

A KICK FOR THE GREEN LIZARD.

A DISREPUTABLE print, which, from its verdant hue, and reptile propensities, we shall denominate the GREEN LIZARD, has done a splutter which it calls giving us "a hint," in return for which civility we shall give it a kick. The thing actually accuses us of telling lies of it! Now this reptile is well known to all versed in herpetology, to have been hatched by the incubation of Sir Benjamin, and Sir Hal, who, resolving to set up something or other to oppose the "inconvenient" journal, unshelled this miserable animal, and condemned it to eat dust under their feet all the days of its life. For some time it very dutifully fulfilled its function; but at last the astute reptile, perceiving that the naughty baronets were regularly floored by the *Lancet* and *Us*, turned short on them, and being naturally stingless, did at least what it could to testify its dislike, by waddling over them backwards as they lay on the ground, flourishing its tongue, twirling its tail, and affording every manifestation of puny malevolence. For the plain statement of the facts here allegorised to render them less disgusting in the repetition, we are accused of traducing our contemporary. Now, although we have said nothing but the truth, we are afraid our conclusions may have been uncharitable—we may have mistaken the results of imbecility for those of treachery. It is possible that the obscure scribe, to us wholly unknown, who conducts this most dishonest hebdomadal, may latterly have sunk into the state of senile fatuity, which prior indications have frequently pointed to—that, having dissipated what brains he had, he now entirely forgets all that he has formerly said or done, and presents the melancholy spectacle of a bewildered wretch, drivelling, with aimless malice, against those from whom he has earned and received the wages of infamy. Lies! And does

our contemporary really think that we would be at the trouble, to say nothing of the wickedness, of inventing lies to injure so poor a thing as the Green Lizard, which, having been crushed and trampled on by the *Lancet* till it has lost even the power of crawling, is carried on a pole by an eminent bookseller* with his advertisements inscribed on its lank sides? No no—we say with uncle Toby "Go thy ways, poor devil, there is room enough in the world both for thee and us." And our contemporary is a nice mild creature after all—he is loth to harm us; he says he will not "break a moth upon the wheel;" yet notwithstanding his benignity we should be very sorry to be moths within the reach of so insectivorous a reptile as the Green Lizard, and as for wheels, the dexterity of our friend at *wheeling* is unequalled; it is one of those accomplishments in which we never hope to rival him. Really, though, we are very glad our contemporary does not mean to slay us, it would be so very terrible if he did!

A word about our following in the path of the *Lancet*. The obscure scribe has the stupidity to bring this as an accusation against us. The idiot! We glory in following the *Lancet*. Of the personalities of that journal we always entirely disapproved, unlike our green contemporary, whose personalities have been quite as coarse, though rather less witty than those of the *Lancet*, and tinged with a malignity from which the latter is free; but in all other respects we sincerely venerate the *Lancet* as the honest, fearless, and powerful advocate of the rights of the profession. We feel it but justice to declare, that if we had not followed the *Lancet*, this journal would never have been what it now is, the most influential of the medical periodicals. The Green Lizard has also *followed* the *Lancet*, but in a dif-

* We hope that no bookseller will suppose that we mean by this allusion the smallest disrespect to him.

ferent fashion—ignominiously dragged at its chariot wheels.

Our pitiful and unknown adversary is reduced to beg that we will not conceive he is afraid of us. He is afraid of us; for although in general an egregious ass, he has always evinced an admirable instinct of self-preservation, and knows too well the difference between his own calibre and ours to enter willingly into a contest with us. The effort with which, after many throes, he has stammered out "the blockhead," is truly ludicrous; it puts us in mind of an Irishman who spat his *own* head out at his mouth in a violent fit of coughing.

Our contemporary may calm his fears, there will be no contest. With *respectable* journalists we shall never decline a tilt when the occasion demands it, though we would always rather cultivate a good understanding with them; but with sordid scribes, unknown to us but as the hirelings of corruption, we cannot enter the lists. We shall never again mention the Green Lizard in our leader, except, as heretofore, to animadvert, in passing, upon its falsehoods, tergiversations, or absurdities.

—o—

ELECTRO-TERPATHY, A NEW MEDICAL DOCTRINE.

Our readers may have smiled at the homœopathic reveries of Hahneman, but they will not do so less at the electro-terpathy to which a M. Bachoué* stands the father. The bantling is developed in 4 vols. 8vo.—a strapping child to carry about. We only undertake to present it's marrow.

Electro-terpathy then comprehends six curative methods, all which are founded on the organic *terpathic* law, (from *ter* three and *pathos* affection), a law discovered by M. Bachoué himself. These curative methods are:—

1. The *fluxipede* method, by which the

humours are withdrawn from the head, the eyes, the ears, the throat, arms and chest.

2. The *fluxiscope*, to withdraw them from the legs, the bladder, genital organs, womb, kidneys, bowels, liver, spleen and stomach.

3. The *insecticide* method, to destroy all the germs, or insects, retained in the vessels.

4. The *physipurge*, or *pulsipore*, to augment the flow of the sweat, urine, and fæces, in the proportions intended by nature, and thus to purge the body by every outlet.

5. The *electrogene* method, to rouse the sensibility and contractility in paralysis, debility, and the various chronic and atonic congestions.

6. The *delectic* method, to dilute the saline materials of the blood, and thus to diminish the excess of sensibility, of heat, and contractility.

—o—

DUPUYTREN'S CLINICAL CHAIR.

THE chair of clinical surgery, rendered vacant by the death of Dupuytren, is not to be filled by concours until the 2nd of January, 1836, thus leaving it vacant nearly a whole year.

—o—

EPIDEMIC TYPHUS IN PARIS.

A TYPHOID fever is prevalent to a great extent in Paris at this time, chiefly among the students of medicine, and labourers newly arrived from the country. Petechiæ of the trunk and extremities, and parotid swellings, sometimes of good, at others of bad augury, are attendant symptoms.

—o—

PRESIDENCY OF THE ROYAL MEDICO-CHIRURGICAL SOCIETY.

To the Editor of the Original London Medical and Surgical Journal.

SIR—The enclosed is a copy of a letter addressed to the editor of the *Lancet* in contradiction to certain calumnies, quasi editorial statements, lately published in that journal (No. 27, for March 21), respecting the Council of the Royal Medical and Chirurgical Society. As a known and personally cognizant witness for the defence, I had in justice and usage a right to expect the immediate publication of my version of the matter. To my surprise, however, the editor, instead of having at once inserted my letter (which was properly authenticated) as he was in my opinion bound to do, has favoured me with,

* Of Vialée in the Department of the Basses (Pyrenées.)

but a promise of publication, and that conditional, viz., provided I shall *distinctly answer six queries* which he proposes; and which are, I may remark, so ingeniously contrived as to keep quite clear of the question at issue, and leave the statements of my letter substantially undisputed; queries, in fact to which I might return six such answers as the editor seems to wish for, without, in any material point, so far as I can see, contradicting my previous averments or confirming his own. Having no means then of compelling the Minors of Essex-street to deviate from the practice of other criminal judges, by admitting pleadings in defence, I have no other alternative than an appeal to a more impartial tribunal.

Under such circumstances, I take the liberty of requesting the insertion of this and its accompanying enclosure in your next Number, and remain,

Sir,

Your obedient Servant,

F. R. M. C. S. L.

To the Editor of the Lancet.

SIR—Your last number contains an article headed, "*Royal Medical and Chirurgical Society*," in which I find the following statements expressed or implied. Viz. 1. That the gentleman who now graces the chair of that Society, is in point of standing, as a member or fellow, next in seniority amongst the surgeons after the last surgical president, Mr. Lawrence. 2. That as senior surgeon fellow, he was entitled and elected accordingly, to the chair on the last vacancy. 3. That a certain piece of "*information reached his ears by a side wind*," i. e. by some non-official or indirect channel. 4. That the council, to extricate themselves from some difficulty, persuaded a particular candidate for the chair to withdraw his pretensions. 5. That the differences of opinion regarding "the presidential question" (to borrow from brother Jonathan) originated in secret and *menial* intrigues in the Society. 6. That the election to the presidency of the Royal Medical and Chirurgical Society takes place according to some "*Rota*."

Now I am not so fastidious, nor, I am sure, is any one of the gentlemen by implication or otherwise censured in your article, so fastidious, as to object to any of your correspondents "*Killing the enemy*," by romancing about the "*Royal Medical and Chirurgical Society*," or any fellow or section of its fellows, provided only he limit the excursions of his fancy to the regions of good feeling, and fair play. But I cannot but protest against statements like those in question,

some of which are mischievous in tendency and apparent design, and all of which are false, both in spirit and in substance.

1. The present president was *not* next in rotation or seniority. 2. He was *not* elected on account of seniority, but on account of weightier considerations, viz. talent, services, &c. 3. *Did not* obtain a certain piece of *information by a side wind*, but by official announcement to himself in person. 4. No candidate for the chair withdrew his pretensions at the solicitation of the council; nor was the candidate you named as "*persuaded*," so solicited to withdraw his pretensions. 5. The differences of opinion regarding "the Presidential Question" did not originate in any negotiations, dark, irregular, or improper, i. e. in *intrigues*. 6. There is no "*Rota*," seniority confers no right to the chair, and on the last occasion, as in most former anniversary elections, there has been a "*passing over*." Your informant has, therefore, whether ignorantly only, or maliciously matters not, misled you into the publication of statements, offensive and untrue, and possibly, also injurious, and I expect from your candour, that having unknowingly published such false statements, you will not hesitate to give the earliest and fullest publicity to the opposite, which are the true.

I have the honour to be, Sir,

London,

Your very obedient,

March 21, 1835.

F. R. M. C. S. L.

—o—

MEDICAL APPRENTICESHIPS.

To the Editor of the Original London Medical and Surgical Journal.

"Cui bono?"

It has been argued by the opponents of medical reform, that many of the alterations which have been suggested, would tend to lessen the respectability of the profession in the eyes of the community, that the present system has advantages which no other could give—in short, that it is a "*pattern of excellent virtue*." What do such men say to the present system of medical apprenticeships? They tell us it is necessary as a preliminary process of education—let us inquire.

The laws of the Company of Apothecaries, require that every candidate for an examination, shall have served a five years' apprenticeship to a member or licentiate of the Company; or, in other words, that five of the best years of youth shall be devoted to the mechanical compounding of medicines, the drudgery of bottle-dusting, and almost solitary confinement, for such are apprenticeships in general, or when even different from that, the difference is not for the better. Exceptions are there to every rule, but very few are they with regard to

this one. We shall not palter about trifles, but there is something so hostile to the liberal feeling of young men in a liberal profession, and very naturally so, to the wording of the indenture of apprenticeship, making them as it does, bounden slaves to an individual, and his family—to obey them, to serve them; and, for this “poor privilege,” he must pay 40*l.* per annum, and go through the various duties of medicine compounder, bottle washer, &c. In consideration of which, the indenture specifies that the master shall instruct the pupil in the mysteries of his art; but, does he do this? does he instruct his (so called) pupil even in the elements of medical science? does he teach him the first outlines of Pharmacy, Chemistry, or *Materia Medica*? No! the whole extent of the knowledge acquired by the medical apprentice, is the dispensing of medicines to the various patients of his master, without knowing for what disease they are used. Even, indeed, should he have to perform the minor operations of surgery, such as venesection, he is ignorant of the relative situation of parts, he knows the danger he runs of wounding the neighbouring artery; but he knows not its situation. He has never heard a lecture on Anatomy; probably never seen a subject; then how can he be competent to perform an operation, which, because it is so common, is erroneously considered as so simple? Is this a reason for the continuance of apprenticeships? If I am to judge of the generality of apprenticeships from my own, and I believe they are generally similar, I could point out other and equally important errors in the system.

The practitioner to whom I was apprenticed, had not a large practice; but he had two public appointments, this, of course, added to the duties of the apprentice, for there was no assistant, and I was alone. Sometimes upwards of twenty patients a-day required advice in the absence of the principal, and I was obliged to assume the *gravitas in modo*, and prescribe, without having the slightest knowledge of the treatment of disease, and without having anything more than a confused idea of the doses of the various medicines. Thus was I frequently, unintentionally, committing errors. My governor was quite a Hamilton, with respect to purgation, and keeping the bowels open, he thought was the main duty of this life, and the calomel pill, and the purgative powder, stood my friends, I fear, too often; but, what could I do? I was told there could be no harm done by purgatives. I fear, my governor did not practise the other half of Hamilton’s prescribed duty, or he never would have ordered me to treat disease; for is not the master answerable for the deeds of his servant?—This evil may not be so prevalent in all cases where an apprentice resides; but in

the greater number of instances the poor are treated by him, or those patients who may come in the master’s absence. Does this tend to raise the character of the profession? Is this another reason why apprenticeships should be continued?

I will not deny, that in some “few and far between” instances, medical men instruct their apprentices, but how rare! the hurry, the fatigue, the anxiety of the life of the medical practitioner, can scarce give him time for the necessary duties of life, and he cannot find leisure for the instruction of his apprentices; but he generally considers they do their duty, if they keep the shop and the dispensary in order, dust the bottles, dispense the medicines, and rise early in the morning! And that his duty is performed, if he finds a quantum suff. of wholesome food. But, let me ask, what is the use of apprenticeship? what is its intention? If a “man must serve his time to every trade,” it is naturally supposed, that he shall have a perfect knowledge of that trade, at the expiration of his apprenticeship: Is it so, in the medical profession? No! it is rather a retarding than an accelerating of knowledge; and from the constant confinement, is no less prejudicial to the body, than to the mind. Five years spent in the mechanical drudgery of compounding medicines, is five years lost in the life of an individual; at that time of life too the most important, the most necessary, to be spent to advantage, to acquire that so necessary to a medical practitioner,

“*Mens sana in corpore sano.*”

If it be so great an evil, and few will deny it, save those who have an interest in things remaining as they are; let us ask, how so bad a practice originated, and that question we may easily answer. Every body knows the Apothecaries’ Company was established by a set of men as profoundly ignorant of medical science, as their successors are now frightened at the mention of the word “Reform!” Every body knows this set of men was selected from the old trading druggists, and the so-called, apothecaries, of the last century, men who had “served their time” to the trade, and acquired all they knew during their apprenticeship; what the extent of that knowledge could have been, I shall not decide, but I should think the master and apprentice were about equal. “*Arcades ambo!*”—that being men of trade, and not of science, they thought a knowledge of the compounding of medicines, and its doses, sufficient for them to practise, on hiding their ignorance, under a quaintness of dress, and a pompousness of speech, which passed with the multitude for wisdom;

“And their words of learned length and thundering sound,

Amazed the wondering patients ranged around.”

Such were the men who had to frame the laws of the Company of Apothecaries;—such were the men who had to give guidance as it were to medical politics; fettered as they were by old prejudices, and swayed by personal interests, they made a seven years' apprenticeship a necessary requisite for a member's diploma. They could not forget that they had "served their time" behind a counter, and the "march of intellect" had not taught them liberality of feeling, or enlargement of views, of "good or evil;" they had worshipped at the shrine of bigotry and ignorance, and they would keep their successors in the same faith, if they could. But the day of Medical Reform is dawning, the opposers of that great advent are already trembling to their fall, and soon the unjust laws that now regulate apprenticeships will be of yesterday, and we may exclaim with joyfulness, "Fuit Ilium!"

Hospital Reports.

WESTMINSTER HOSPITAL.

Medullary Sarcoma of the Neck.

WILLIAM DOWSETT, aged 73, was admitted February 24th into Burdett Ward, under the care of Mr. Guthrie. His residence has been at Epping, where he worked as a blacksmith, and enjoyed perfect health until about seven months ago; at which period he perceived a small but hard lump in the neck, situated, according to his description, just behind the posterior margin of the sterno-cleido mastoideus muscle, and about two inches below the mastoid process of the temporal bone. As far as he recollects, at this period the tumour was not moveable.

It did not at first attract much of his attention, until, beginning to increase rapidly in magnitude, he consulted Mr. Mac Nab, of Epping, respecting it; and after having been some time under that gentleman's care, he procured his admission into the Westminster Hospital. At present the tumour has attained a very considerable magnitude, being at least as large as the human fist, and extending downwards, from between the mastoid process and angle of the jaw, and encroaching anteriorly upon the summit of the neck in the direction of the base of the inferior maxilla. It is lobulated, scarcely in the least degree moveable, is covered by integuments of a deeply livid or reddish-purple hue, through which may be seen numerous veins in the subcutaneous cellular tissue, ramifying upon its surface. It is the seat of paroxysms of pain, of an acute lancinating kind, which are either induced or aggravated by coughing. During the last four or five weeks, deglutition has been somewhat impeded, from the progressive encroachment of the tumour upon the pharynx; and this is noticed more par-

ticularly in the deglutition of bread. He states, that since he has been the subject of this disease, he has lost four or five stone in weight, and that he has become proportionably feeble. The tongue is covered with a whitish coat of fur, the bowels are open, and appetite good; the pulse 96 and feeble.

28th. To-day the patient was brought into the operating theatre, in order that the surgeons might severally examine him, and consult on his case. Mr. Guthrie stated, that had the patient been a younger man, say ten years younger, he should not have hesitated in proposing an operation for its removal, as affording a chance of prolonging his days, but that at the age of 73 he could not entertain the idea. Sir A. Carlisle thought an operation quite out of the question, as, from the rapid progress of the tumour, it was evidently of a highly malignant kind, and would in all probability return in the event of the operation being successful, which, however, from the peculiar locality of the tumour, was highly problematical. Mr. White and Mr. W. B. Lynn having been called away from the theatre, did not openly express their opinions on the case; this, however, was perhaps unnecessary, as it appeared that the patient had already made up his mind not to undergo any operation. Mr. Guthrie observed, that it was advantageous to have even irremediable cases of this description in the hospital, as it afforded them an opportunity of studying the course of diseases, which might not otherwise come under their observation.

March 21st.—The tumour continues to increase in size, extending in front of the ear, on to the surface of the cheek, and below the jaw towards the submaxillary gland. The difficulty of deglutition increases.

26th.—Having requested to be allowed to return home, he was yesterday discharged, as "incurable."

MIDDLESEX HOSPITAL.

Fistula in Perineo, after Lithotomy—Operation.

APRIL 1st.—A boy, aged twelve years, had a calculus removed from his bladder, by the ordinary lateral operation, when about six years of age; and the wound in the perineum, having never entirely healed, has left a fistulous opening between the bulb of the urethra and the anus, which communicating with the bladder, permits the urine, when the patient is in the erect position, constantly to dribble away, which producing excoriation of the nates, thighs, &c., is a source of great irritation and annoyance.

With the view of obtaining him relief, his father had procured his admission both into the Westminster and St. George's Hospitals, where a variety of measures were tried with-

out success. Amongst these may be particularized—the recumbent position with a catheter in the urethra, and the application of the potential and actual cauteries to the opening of the fistula.

Under these circumstances, Mr. Mayo determined to try the plan of laying open the fistula from its external opening to its commencement in the bladder.

The boy having been placed in the same position, and secured in the same manner as in the operation of lithotomy, Mr. Mayo followed almost precisely the usual steps of that operation. A staff was introduced through the urethra into the bladder, and a director passed into the fistula, which was then carefully laid open by means of a probe-pointed bistoury. An elastic-gum catheter was then passed into the fistula thus laid open, where it is to be allowed to remain in order to excite the wound to granulate; after which the patient was conveyed to a bed in one of the wards.

Necrosis of the Tibia—Operation.

A youth, aged seventeen, was next brought into the theatre, in order to have the sequestrum removed from the head of the left tibia, which has for some time been in a necrosed state. A longitudinal incision, about two and a half inches in length, was made through the integuments, and the surface of the diseased bone exposed. Mr. Mayo now proceeded to apply the trephine, and a circular piece of new bone was thus removed, and by the fresh application of the trephine, a fresh segment of bone was taken away, by which means the opening was enlarged. The sequestrum thus exposed, was, after the use of a variety of forceps, and not without considerable labour, extracted in three or four portions.

NORTH LONDON HOSPITAL.

—
Rhinoplastic Operation.

JANE CAMPBELL, aged 19, admitted January 26, under the care of Mr. Liston. She labours under very great deformity, from complete destruction of the nose, as high up as the nasal bones. The loss of substance was the effect of intractable ulceration, which commenced about five years ago, without any known cause. The ulceration, which commenced on the right cheek and affected successively the nose and left cheek, proceeded in defiance of a variety of treatment for about three years, when it had effected the loss of substance as it at present exists; it then began to get well spontaneously and in a short time completely cicatrized. The patient being extremely anxious to get rid of the deformity, consented to submit to an operation.

On the day of her admission, the operation was performed in the following manner. The size of the flap, which it would be ne-

cessary to bring down from the forehead, was first measured with a piece of soft leather, and then, as it was expected the patient would be rather unsteady, was traced out with ink. The cicatrized edges where the cartilages of the nose formerly rested, were then paired off pretty deeply. The flap was next dissected down—its attachment to the root of the nose was left of proper thickness, so as to ensure a sufficient vascular supply. The incision on the left side, to which it was proposed to make the turn, was carried down a little lower than on the right, so as to facilitate the twisting.

After the bleeding had ceased, the flap was brought down, and retained in contact with the surface prepared for it, by two points of interrupted suture on either side.

The lower part of the wound on the forehead was also brought together by a single stitch, a little oiled lint was then placed in the nostrils, so as to support the flap. On the second day the sutures were removed, a strip of isinglass plaster having been first applied. Adhesion was found to have taken place all round.

Lint dipped in warm water and covered with oiled silk, to be applied to the wound in the forehead.

March 5th. A narrow bistoury was passed under the twisted portion, and its attachment with the forehead divided.

A thin wedge-shaped portion was removed, and the raw surfaces were brought together, and retained by three points of suture.

Mr. Liston said, this operation is generally required in this country, from the ravages produced by the abuse of mercury, or by the venereal disease. Sometimes the nose is lost as the consequence of exposure to violent cold, and from debility following fever.

The operation was practised considerably in the fifteenth century; and it is mentioned by writers at the commencement of the Christian era. In the fifteenth century, the flap was cut from the upper arm; you no doubt remember the facetious manner in which Butler, in his *Hudibras*, has spoken of the operation as practised by Tallicotius. A German surgeon lately practised the operation in the manner of the fifteenth century; he failed in the first case; but, thinking he might succeed by getting the parts into a more favourable state for adhesion, he cut through the integuments of the upper arm, put a seton through the flap, and allowed it to remain there for a short time: he then removed the flap to the nose, and it adhered; the operation was successful.

The operation as now practised, though variously modified, was introduced from India in 1795; where it had been practised for centuries; it is simple, more successful, and less painful to the patient. It is said the Indian operators used to pommel the in-

teguments for the new nose with a slipper, to excite the circulation, and produce thickening.

I have had to deal with patients in whom all the cavities of the nostrils was destroyed, producing much greater deformity than in the case before you. Shortly before leaving Edinburgh, I made a flap three times as large as in this one; you must always proportion the flap to the size of the ossa nasi. There are few points of suture necessary after the operation, provided the incision corresponds, and you do not pucker the parts; by a few points of suture you allow the free discharge of the matter, which I need scarcely say is of great importance. With regard to the various modes, I have practised the Indian one, but the form of their flap in general encroaches on the hairy scalp; it did so in the first case I had, and I could not produce union of the column. There is a great variety of opinion as to what form the flap should be of; that recommended by Delpech causes too much deformity.

I have frequently asked, "What do you make the bridge of?" Mr. Tyrrell, of St. Thomas's Hospital, has tried one made of platinum wire, but it came away in a very short time. He still, however, adheres to his opinion as to its usefulness. Now, in fact, there is no necessity for you to make an artificial bridge; the flap at first is exceedingly moveable, but after a time its under surface begins to granulate, and it then rests on the ruins of the old nose, becomes, as it were, part of it, is firm and consistent, and is endowed with sensibility.

Our patient, as you are aware, cannot yet make up her mind to submit to the completion of the operation—the column being still required. This part of the operation I have practised for years successfully in cases in which the column has been lost by ulceration: it consists in passing a sharp-pointed bistoury through the upper lip, about an eighth of an inch on one side of the medial line, close to the ruins of the old column: you will continue the incision downwards, straight to the free margin of the lip; a parallel incision is then made on

the opposite side of the medial line, and a flap is formed of skin, mucous membrane, and interposed substance: you then divide the frenulum, and remove the prolabium, and without twisting, fix the flap in its required position, by means of a sewing needle headed with wax, being passed through the apex of the nose and the extremity of the elevated flap. The edges of the lip may be brought together by twisted sutures. This part of the operation, instead of producing, generally prevents deformity—for you will always find the upper lip tumid and elongated after the loss of the column: you remove the deformity of the lip, and improve the nose, by the last-named stage of the operation.

I think I may claim this operation to myself: I proposed it twelve or fifteen years ago, in the case of a young gentleman whose septum narium and columna inflamed and ulcerated, in consequence of a blow.

With regard to the wound in the forehead of our patient, you will perceive it is not quite closed—there is a slight exfoliation of bone. this accident never occurred to me before, and will not now be attended with deformity.

—o—

Diseases of the Lymphatics.

I HAVE ascertained, says M. Velpeau, that at least fifteen times out of twenty, the engorgement of lymphatic ganglions is preceded by some inflammation, or suppuration of some other point; that the glands of the neck, for instance, in scrofulous persons are swelled in consequence of some previous disease of the head or mouth: the swellings of the armpit are referable to similar causes, in the hand, arm, or chest; those of the groin, to some cause in the lower extremities or sexual organs, &c.

The practical deduction from this is, that, in children for instance, it is important to put a stop at once to any suppuration, to reduce every inflammation about the scalp or head, instead of leaving them, as is frequently done, when the patient is threatened with scrofula.—*Gazette des Hopitaux.*

VOL. VII.

LECTURES ON MEDICAL JURISPRUDENCE,

DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,

At the University of London; Session 1834-35.

LECTURE XXV.

GENTLEMEN—In forming a prognosis of wounds, for medico-legal purposes, several circumstances besides the character of the wound itself are to be taken into account: as for instance the *age* of the patient. It is evident that as life advances, wounds become more hazardous, and are less likely to healowing to the diminished energy of the circulation, the obliteration of many of the minute vessels, and the general loss of tone which is peculiar to the latter years of life. The muscles become loose, flabby, and relaxed, consequently, the powers of healing and reparation of injury to those parts are diminished; life is altogether less stable than in youth, which rebounds as it were with an elastic force under the depression of injuries, whilst in the old, the lessened degree of vital power renders every injury a more or less permanent evil. Any thing exciting inflammation of the skin, particularly of the extremities, is apt to terminate in mortification in the old; thence, wounds which in themselves are trifling, in the young and middle-aged, become serious and mortal in the old. But besides the period of life, considerable difference exists in the original fabric of the body; some are born with vigorous constitutions, others with feeble; some are not affected by any thing, others are of the most excitable temperaments; in all of which, differences must necessarily take place in the issue of injuries; and thence, also, the necessity of attending to the constitution in forming a prognosis respecting wounds. In some instances, danger may arise from peculiarity of original structure: the heart may occupy the right side of the thorax; the stomach has been found below the umbilicus, whilst the bladder has been found above it. In the body of Smithers, who was hanged for

VOL. VII.

arson, which is preserved in the Museum of the University, you will find that every viscus, both of the thorax and the abdomen, is transposed. Thus a wound on the right side, in this man, would have penetrated the heart; or, if in the abdomen, one on the left side might have passed through the large lobe of the liver, wounded the gall bladder, or penetrated the pyloric portion of the stomach. These deviations render a person who is wounded more or less susceptible of danger than he would otherwise be; but, except in cases of premeditated murder, wounds becoming dangerous only from mal-position of parts must always be viewed in a point favourable to the accused, and the deviation accurately pointed out to the court by the medical witness, and the probable consequences of these, as they bear upon the case under consideration, made evident. In the case, which I had occasion to notice in my last lecture, of a boy having died from blows on the head from a small stick, no danger would have followed the blows but for a peculiarity in the bones of the head, which were remarkably thin and brittle; and consequently the accused had very properly the advantage of this deviation, and was acquitted.

Slight wounds are, also, sometimes rendered dangerous in persons extremely irritable; or, diseases may exist, which even independent of wounds or blows would have soon terminated fatally, and questions may thus arise whether death is to be ascribed to the wound or to the disease. Some persons have what is termed a hæmorrhagic constitution, so that, when even slight wounds are inflicted, they immediately become dangerous from the great loss of blood; or there may be variations in the ordinary distribution of blood-vessels, which may render slight wounds equally hazardous, as in persons with a hæmorrhagic constitution. The trade of the wounded person should not be overlooked in forming a prognosis of the probable consequences of wounds. A man receives a blow on the head, it is not much thought of; but after some days he is seized with vertigo, staggers, drops down, and dies. The blow is suspected to have been the

△ △

cause of his death; the head is opened; a vessel is found ruptured, sufficient to account for his death, and the individual who struck the blow is arrested and put upon his trial, either for murder or manslaughter. The evidence that he struck the blow is clear; and he is about to be condemned. Now this person may be perfectly innocent. If the occupation of the deceased led him to lift heavy weights, and the vessels of the brain were in a brittle state, the temporary congestion in the head, owing to the retention of the breath which always accompanies efforts to raise great weights, would be likely to rupture a vessel, and the death of the individual have no connection whatsoever with the blow to which it had been attributed. That such a state of vessels as this occurs is well known; death from rupture of vessels in the brain may even arise from more obscure causes; and this fact displays the necessity of not forming an opinion in cases of the fatal result of supposed wounds or blows, without investigating closely, both the nature of the employment, and the state of health of the person who died.

Again, wounds in themselves not dangerous may bring on diseases in some vital organ, which may terminate fatally. Thus, inflammation of the lungs is not an unfrequent cause of death from wounds, and more especially of compound fracture: yet it would be far from just to condemn a man for inflicting a wound which might induce such an inflammation in one case, when a thousand of a similar description and as severe recover. In giving, therefore, an opinion as to the cause of death after the infliction of a wound, the lungs, as well as the wounded part, should be most carefully inspected; and, if indications of inflammation having recently existed there display themselves, the accused most undoubtedly ought to have the benefit of the observation. But even before death, you should be able to form a probable prognosis in cases of this description. Two men fight a duel, and one is hit in the arm so as to produce a compound fracture of both radius and ulna. His antagonist is arrested to await the issue of his wound; on the second day the inflammation assumes a dark colour, with a gleety discharge, and he becomes restless and irritable, with a quick pulse, and pain seizes him in the side; you may pronounce him in great danger, but not from the extent or nature of the wound, but from the state in which his system was when he received the wound. If he be, otherwise, in a weak and irritable state, the inflammatory attack may be veiled, and the practice adopted consequently feeble; the disease will run on and terminate in death. Dissection, in such cases, exhibits marks of recent inflammation in the lungs, coagulable lymph exuded, and not unfrequently purulent matter on the surface of the lungs,

or in the bronchial tubes. Besides, therefore, being cautious in forming a prognosis in such a case, the knowledge of this close connexion betwixt wounds and the lungs, should make us watchful of the first symptoms, the appearance of which will always be a guarantee for the most active practice.

Another consideration not to be overlooked in forming a prognosis of wounds, is the state of the weather and the site of the residence of the individual, in reference to its salubrity or insalubrity. Extreme of cold or heat, thunder storms, much rain, snow or hail, all increase the danger of wounds. An insalubrious atmosphere may render slight wounds dangerous, and dangerous ones mortal. A wounded man carried into an hospital where cases of gangrene are at the time, or into a hut near a dunghill where putrefying animal and vegetable matter is collected, or, in fact, in any place in which nitrogen, carbonic acid, and sulphuretted hydrogen, are present in any considerable quantity, cannot be expected to get well; thence a large proportion of the wounded patients of overcrowded hospitals die, not from the wounds, but of hospital gangrene; and, under such circumstances, Dr. Beck justly remarks, "It is the duty of the medical examiners to apply the maxim of Hippocrates, that every thing which happens to the injured person contrary to correct probability, does not belong to the essence of the disease." It must, however, be also kept in remembrance, that of the causes of death, in such a case, although the wound is the slightest, yet, it may have contributed materially towards the development of the others.

The last consideration to be attended to, in forming a prognosis of wounds, is one which I would most willingly throw a veil over—the want of skill or negligence of the surgeon in whose hands the wounded person may have fallen. Hæmorrhages that might have been suppressed in other hands, may prove fatal from ignorance of the mode of taking up vessels; collections of pus may not be evacuated when necessary; operations may be either neglected or improperly hurried, and imprudencies in diet may be permitted. A case of death arising from a tight bandage is detailed by Sir C. Bell, in his *Surgical Observations*. (See p. 294).

A most instructive case of the fatal effects of abuse in diet and regimen, even in recovery from severe wounds, is given by Dr. Hennen, in his *Military Surgery*, p. 353.

In cases of decided malpractice, no feeling of delicacy towards the surgeon should prevent from giving an opinion favourable to the author of the wound, and openly attributing the blame, if merited, to the surgeon. No medical man can stand excused for failing to make himself acquainted with every improvement in his profession, and to

apply it to the symptoms presented to his view; and then, if on examination the injury is found to be such that no effort of art could have prevented its fatality, the death of the patient may be justly attributed to the nature of the wound. On the contrary, the prompt attention to take advantage of every favourable occurrence sometimes happily saves life under the most threatening aspect of affairs. I have some hesitation in illustrating this remark by an anecdote of myself; but I am induced to forego the silence which I would otherwise maintain, by having observed the following note in p. 333 of Dr. Darwall's edition of Dr. Beck's *Elements of Medical Jurisprudence*: "There is one instance, and only one, of a divided carotid not proving fatal. In this instance, Mr. Carpue, of London, being called at the moment, secured the vessel."

(The lecturer here related a case of a gentleman who cut his throat in a shop at Knightsbridge).

Although the law of England looks to the intent, and little to the nature of the wound, in criminal cases of wounding, yet the enactment passed in the reign of James the First, which refers to the period within which a person, who has been wounded with a criminal intent, must die in order to constitute that act murder, is still in force. It declares, "That the thrusting or stabbing another, who has not a weapon drawn, or who hath not then first stricken the party stabbing, so that he die thereof within six months after," shall be adjudged murder, though done upon sudden provocation. The same provision, as to time, constitutes, also, part of the law of murder in other countries. The difficulty, in all cases, is to trace the death clearly and indisputably to the wound in question. It is well known that after serious wounds, from which the persons recover, the organs in the different cavities of the body have their disposition to disease very much increased; and causes which, in a state of health, would scarcely affect them, operate very powerfully. Thus, for example, a man receives a wound in the thorax, the slightest atmospheric changes affect the respiratory organs; some months after the wound is well, he catches cold on a slight exposure, inflammation ensues, and he dies. Another is wounded on the head, but recovers; before six months expire, he makes some violent effort, in lifting a heavy load, or he is transported into a violent paroxysm of anger, or commits an excess in drinking, phrenitis supervenes, and he also dies. In both these instances an advocate might contend that the death should be ascribed to the wounds, as, unless these had rendered the habit so susceptible of diseased impressions, the individuals in all probability would not have suffered. But it is not in this light that such cases are to be viewed by the surgeon, and he would ill perform his duty to consign the accused to punishment on such

grounds. On the other hand, in such a case as the following, and in many others of a similar nature, in other cavities, there can be no hesitation in tracing death to the wound, however long before the fatal issue takes place. "A ball entered the right eye of a French soldier, towards the great angle, and could not be traced. He himself deemed it of little consequence; and the wound healed under the common hospital treatment. Some weeks afterwards the man expressed a wish to leave the hospital, although cautioned by the surgeon, and had scarcely reached the door, when he was seized with rigors, obliged to return, and died two days afterwards. On dissection, the ball was found lodged under the sphenoid cells and the hole of the optic nerve." (Garangeot *Traité des Operations*, vol. iii, Obs. 20). As confident an opinion may be, also, delivered in cases in which pieces of cloth have been carried into the abdominal or thoracic cavity by bullets; and, being left there, have caused abscesses, which have afterwards terminated in death. But, perhaps, it is much safer in every case to look to the intent, whatever may be the consequences; thence the advantage of Lord Ellenborough's act, in removing many of the difficulties which crowded upon the surgeon in delivering evidence in courts of law, relative to such cases.

In instances of insurance upon lives, in which suicide is suspected or alleged, it is of much importance to ascertain the fact, as cases have occurred in which the wounds supposed to have been the cause of death, have been inflicted after death; and this has also been done with the view to conceal murder. A wound, however, received during life, either exhibits appearances of incipient inflammation, or it causes greater hæmorrhages than one made after death. In such cases, also, if any weapon be found near the deceased, we should ascertain whether that could possibly have inflicted the wound, or whether it has been placed there afterwards. Two cases of this description may be mentioned. The first is that of Sir Edmonsbury Godfrey, who had been strangled, and thrown into a ditch, where he was discovered with his own sword run through his body; but, as no blood issued from the wound, an inquiry was instituted, and the means by which he was killed ascertained. The second case is that of a man who was found shot, and his own pistol lying near him, from which circumstance it was concluded that he had destroyed himself; but, on examining the ball by which he was killed, it was discovered to be too large to have entered that pistol; in consequence of which, suspicion fell on the real murderer.

Such, Gentlemen, are all the remarks which I think necessary to be brought before you relative to wounds. With respect to *mutilations*, the law of England takes special notice of these under the term *mayhem*, a legal term for maiming. It is scarcely ne-

cessary to say that a *mutilation* comprehends both a wound and a permanent deformity or deprivation of some organ or part of the body, which weakens or destroys the functions of one or more parts. By the eye of the law it is viewed in the same light: "The term *mayhem*," says Judge Blackstone, "is the violently depriving another of the use of such of his members as may render him the less able in fighting either to defend himself or annoy his adversary. And, therefore, the cutting off or disabling, or weakening a man's hand or finger, or striking out his eye or fore tooth, or depriving him of those parts, the lac of which in animals abates their courage, are held to be *mayhems*. But the cutting off his ear or nose, or the like, are held to be *mayhems* at common law, because they do not weaken, but only disfigure him." But, nevertheless, castration was always held to be felony; and this, although the *mayhem* was committed upon the highest provocation; cutting out the tongue, putting out the eyes, slitting the nose, or cutting it off, were also afterwards, by an act of Charles II., declared felony without benefit of clergy. The number of acts under *Mayhem* are numerous. (See Russell, p. 585.)

In looking over this list of offences constituting *mayhem*, one is surprised to find so much value put upon the fore tooth at the early period at which the law was enacted: had the enactment occurred at a later time, after the use of the cartridge, for loading military muskets was introduced, we might understand the object, as a soldier is obliged to bite off the end of the cartridge before the powder can be discharged from it. It was not very honourable to the English law that it visited slitting the nose with the punishment of death, and permitted more serious wounds to be inflicted with impunity. So late as 1778, one Tickner was tried at the Old Bailey, under the Coventry Act, that enacted in the reign of Charles the Second, to

which I have alluded, for injury done to one William Jacob. There were several wounds, but the one which bore chiefly on the case, was a cut on the nose dividing the integuments in an oblique direction; the wound was slight, but sufficient to leave a visible mark for some time. The prisoner was convicted; but Serjeant Glynn ordered the execution to be respited until the opinion of the twelve judges could be procured, whether this conviction was proper within the meaning of the Coventry Act. The judges decided that the conviction was right; yet, fourteen years before this trial took place, one William Lee was tried for attempting to cut his wife's throat with a razor, while asleep. The wound was three inches in length and quite across, but did not prove mortal; this was held not to be an offence within the Coventry Act.

With regard to the law on the aggravation of injuries by injudicious treatment: it is sufficiently explicit respecting persons not qualified to practise surgery; but it is less so, respecting the malpractice of those who have been licensed as surgeons. It was anciently holden, that if a person, not duly authorized to be a physician or surgeon, undertake a cure and the patient die under his hands, he is guilty of felony. By a statute of the 23rd Henry the Eighth, the capital part of the charge was set aside, and it now only constitutes manslaughter. But the late trial of a notorious quack for the death of a young lady, which is too fresh in your memory to make it necessary for me to go into particulars, demonstrate to you the difficulty of substantiating charges of this description. Whether the public would sympathize with a regularly educated surgeon, in the same degree as it did with the notoriously ignorant pretender on that occasion, I will not take upon me to decide; but, for the honour of the profession, I trust the experiment may never be tried.

LECTURES

ON THE

INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE XVIII.

Evidences of the Ganglionic System of Nerves being the true seat of Irritability.

THE question then recurs—Do the various movements, molecular or sensible, in the sum of which life consists, and the only generally acknowledged instrument of which, at least in the higher tribes of organized beings, is muscular fibre, whether insensible, as where it invests the capillary and erectile tissues, or sensible, as where it constitutes the obviously muscular organs, indicate that muscular fibre is the immediate seat of irritability; or may the impression of the stimulus, by which this fibre is excited to contraction, be presumed to be made first upon some part of the nervous system—which in this case must be

regarded as the immediate seat of this property—and communicated to the muscular tissue only secondarily (a)? That the nervous system—in the vague sense in which the term was formerly, and still unfortunately is too frequently employed—was the immediate seat of irritability—a property in so many respects analogous to irritability—had become firmly established among physiologists long before the existence of the latter as a distinct attribute of organized beings was suspected; and it was therefore natural that, upon the introduction of this new property, a local habitation should be assigned to it similar to that which the property so nearly allied to it had so long occupied. It was indeed at this time almost universally admitted, that the nervous system—by which term was then almost exclusively understood the cerebro-spinal department, was alone susceptible of vital impressions of any kind—that is to say of undergoing, upon the application of a stimulus, any change not strictly either chemical or mechanical—and that it was by means of this system alone that the effects of such changes were extended to the other parts of the body: but the opinion, however well founded with respect to sensibility, had hitherto no support, except that of analogy, in its extension to irritability (b). Some circumstances accordingly connected with the property of irritability soon began to attract attention, which were not easily reconcilable with the generally prevalent hypothesis. Independently of the circumstance that the proper cerebro-spinal nerves—which alone were then generally recognised—were too circumscribed in their immediate distribution to explain the communication by this means of a universally disseminated property, and of the obvious fact that all the functions of the body which consisted merely in irritation, or required for their exercise the property of irritability alone—in other words all the organic functions—continued uninterrupted during sleep, in comatose diseases, and even for some time after apparent death, in all which cases those nerves are to a greater or less degree in a state of inaction, it was soon proved by direct experiment, not only that a stimulus applied to all appearance directly to a muscle fibre, had the effect of exciting its contractions (c), but also that this susceptibility of contraction, or irritability, was not materially impaired by dividing the principal nerves with which it was furnished, by removing the brain, or even for some time by totally separating such muscle from the rest of the body; and further, that if the irritability of a muscle, the nerves of which had been de-

(a) It is assumed above that motion, insensible or sensible, is always a concomitant of irritation, and regarding irritation and life as synonymous terms, and life as consisting in a series of motions, such an assumption is unavoidable. It is by no means certain however, as will be more fully explained in future, that irritation, or the “perceptio” of Glisson, is always followed by motion of any kind, although it is by such motion alone that we are capable of recognizing its existence.

(b) Such was however the vague surmise of almost all the earliest authors upon this property, who, in their ignorance or carelessness of the plurality of the nervous system, while they expressed what is in all probability the truth when they referred irritability to this system, signified, at the same time, what is in all likelihood the most remote from it; since they meant in general, when they meant any thing definite, a department of this system which is perhaps as little allied to that which is really the immediate seat of irritability, as this latter is to the muscular, or any other system of the body. Of this stamp were, besides many of the authors already enumerated, in particular De Gorter, and Hoffman, Senac (*De la Struct. du Cœur*, 1749), and Whytt (*Physiol. Ess.* 1755); and the same doctrine has been maintained since the time of Haller, principally by De Haen (*De Sensib. et Irritab. Hum. Corp.* 1761); Unzer (*Erste Gründe einer Physiol.*, &c. 1771); Cullen (*Instit. of Physiol.* 1777); Scarpa (*De Nerv.*

Gangl. 1779); Monro (*On the Struct. and Funct. of the Nerv. Syst.* 1783); Schaffer, (*Ueber Sensibilitat. &c.* 1793); Prochaska (*De Carne Musculari*, 1798); Le Gallois, (*Sur la Principe de la Vie*, 1812); and some others. In this enumeration are included only those authors who have either expressed or signified that irritability is seated primarily in the cerebro-spinal system of nerves—or that which alone had, before the recognition of irritability as a distinct property, attracted any considerable attention—or if they have referred it to the ganglionic system, it is only in the idea that this constitutes merely an appendage to the former. If it is possible to agree with persons in fact, while we differ from them most materially in the words used to express that fact, it is equally so to agree with them in words—as when they refer irritability to the nervous system—and still differ from them *toto cœlo* in the fact implied.

(c) It was the observation of this fact, as already observed, which first led some certain physiologists who were predetermined that no other but the nervous tissue, in their sense of the word, *should* acknowledge a vital impression, to represent the muscles as merely an expansion of the cerebro-spinal nerves, and to class the two together under the name of “*Solidum Vivum*,” in contradistinction to the “*Solidum Mortuum*,” which included every other tissue of the body. Dr. Gregory, (*Conspect. Med. Theoret.* 1790), is very full and edifying on this subject.

stroyed were by any powerful stimulus—such as that of Galvanism—suddenly so far destroyed, as that it ceased to obey any stimulus whatever, it was after a time more or less perfectly restored. All this appeared to be quite inexplicable upon the hypothesis that irritability had its immediate seat in the nervous system, in the circumscribed sense at that time attached to this term, and led many physiologists to regard this property, unlike sensibility, as the immediate attribute of the muscular fibre (*a*). But objections soon presented themselves to this inference; and, among the rest, it became a problem, upon this presumption, why the heart and other organs which minister exclusively to the organic functions, and which are neither possessed of sensibility nor under the dominion of the will—the only two purposes, it was said, to which, if they are to be excluded from that of imparting irritability, nerves can be supposed to be subservient—should be supplied with nerves at all; and this problem was found so difficult of solution, that, while it betrayed the founder of the doctrine into innumerable inconsistencies, it has driven some of its later advocates boldly to deny that the nerves furnished to the heart and other organs above alluded to, are of any use at all (*b*), while others have, with still greater boldness, denied the existence of any such nerves in the actual substance of the organs in question (*c*). Others again have regarded these nerves not as the seat of any susceptibility which these organs manifest, nor the vehicle of any stimulus which they ordinarily obey, but as the channels by which extraordinary stimuli, such as that of the passions, are conveyed to them (*d*): and this is probably the truth, but it does not appear to be the whole truth. For it must be remembered that all the organs under consideration derive their nerves from at least two distinct sources—the ganglionic system, or that of the great sympathetic nerve, and that department of the cerebro-spinal system which is called respiratory, and to which the pneumo-gastric nerve belongs—and it appears to be the latter alone, as will be in future demonstrated, which is useful in the manner above supposed, so that the object with which they are furnished with the former is still unexplained.

Upon a fair review then of all that has been said on the one hand in favour of, and on the other in opposition to the two hypotheses which would refer irritability respectively to the nervous and muscular systems, we shall find that, while the former has the strong argument of the most direct analogy in its favour, and every objection which has been urged to it applies only to one department of the nervous system, although unfortunately that of which alone the early patrons of the hypothesis in question took any account, the latter, opposed as it is to all analogy, has been adopted only as a kind of alternative of a doctrine which, in its proper acceptation, has never been refuted, and is liable to objections which are apparently unanswerable. It has been recently shown, moreover, that the effects of narcotic substances and other agents, when applied to irritable parts, are the same, with respect to irritability, as when applied to that portion of the nervous system which is known to be appropriated to sensibility, with respect to this property (*e*); a circumstance which is decidedly in favour of the theory which would refer the former property, as well as the two latter, to the nervous system, in some one or other of its departments (*f*).

But if this theory is to be adopted, we must be prepared to show, 1. That there is a system of nerves, which, unlike the cerebro-spinal, is universally distributed over the body, and furnishes every muscle, whether ministering to the organic or animal functions, since

(*a*) The doctrine appears to have originated with Haller, the father of the *Vis Insita* department of irritability (*El. Physiol.* lib. iv. s. 5, and lib. xi. s. 3), and has been since advocated principally by Zimmerman (*De Irritabilitate*, 1751), Oeder (*De Irritabilitate*, 1752), Dr. Battie (*De Princip. Anim.* 1757), Fontana (*Atti dell' Acad. delle Sc. de Siena*, 1775), Blumenbach (*Inst. Physiol.* 1786), and Soemmering and his pupil Behrends (*Dissertatio qua demonstratur cor nervis carere, &c.*, 1792), and recently in this country, by Dr. Wilson Philip (*Phil. Trans.* 1815, and on the *Vital Functions*, 1817). One only of the above-mentioned data, on which this doctrine is founded, appears to have been questioned, and that is the recovery, after a time, of its irritability by a limb, the principal nerves of which have been divided, and the irritability afterwards destroyed, which, according to Mr. Earle, if the destruction have been perfect, does not take place. Dr. Alison how-

ever, assisted by Dr. Boswell Reid, has established the fact that, if the means taken to destroy the irritability be not such as to disorganize the muscles, this irritability is after a time restored. (*Mem. read to the British Scientific Association, &c.* 1834).

(*b*) Fontana.

(*c*) Soemmering and Behrends.

(*d*) Wilson Philip.

(*e*) Dr. W. C. Henry, *Ed. Med. and Surg. Journ.*, 1832.

(*f*) "The nerves," says Tiedemann, "are an essential condition in the vital manifestations of the muscles. This condition doubtlessly consists in the communication, by the nerves which ramify on the muscles, of an aptitude to be affected by excitants; the action of stimuli inducing the contractions of the muscular fibres only by means of an action upon the nerves." (*Tiedemann's Physiology*, translated by Gully and Lane, 1834, § 443).

the source of the irritability of all is unquestionably the same. 2. That this system of nerves, again, unlike the cerebro-spinal, continues to impart the quality which it is its office to furnish, during sleep and comatose diseases, and even for some time after apparent death. 3. That the filaments of this system of nerves, as distributed upon the muscular fibre, are often so minute as to be quite invisible. 4. That the quality derived from this system of nerves is not intercepted, like that derived from the cerebro-spinal system, by the division of the principal trunks proceeding to a muscle, by the removal of the brain, nor even, for some time, by the total separation of such muscle from the rest of the body. And, 5. That this system of nerves is competent, when the principal nervous trunks of a muscle have been divided, to renew that quality which it is its office to impart to it, if this have by any means been artificially exhausted. Now all this can be, if not demonstrated, at least rendered highly probable with respect to the ganglionic system of nerves, or that of the great sympathetic, so that no fair opposition to the theory in question, upon any one of the objections which were formerly regarded as fatal to it, can be sustained; and indeed, if irritability is to be referred to any department at all of the nervous system, this seems to be the only one which remains for it, the offices severally of the three departments of the spinal cord and their nerves, and of the brain—cerebrum and cerebellum—having been tolerably well established as quite distinct from that of imparting irritability (a). But, besides these negative arguments in favour of the doctrine that irritability has its immediate seat in the ganglionic system of nerves, not a few positive arguments may be adduced on the same side. Of these may be mentioned, 6. The earlier appearance, as we rise in the scale of animals, of this system of nerves than of any of the rest, corresponding with the exclusive display, by quite the lower tribes, of the property of irritability. 7. Its taking precedence also of all the rest in the order of its development in the human embryo, in correspondence with the earlier manifestation, by the fetus, of irritability, than of any other property of the nervous system. 8. Its being rarely or never found wanting in mature human monsters, appearing to indicate the greater indispensability of this system—as the source of irritability—to life, than of those departments of the nervous system which minister to sensation and thought, and which are so frequently defective. 9. Its being relatively more developed in infants and females, than in adults and males, corresponding with the higher degree of irritability in the former than in the latter. 10. Its

(a) It was formerly presumed with great vagueness by Willis (*Anatome Cerebri*, 1664), followed by Vieussens, Boerhaave, Du Hamel, and others, that, while the voluntary motions depended upon the cerebrum, the involuntary, such as that of the heart and other organs which minister exclusively to the organic functions, depended upon the cerebellum and its presumed offset, the pneumo-gastric nerve, which has been taken as equivalent to ascribing to the cerebellum the origin of irritability. It should be mentioned, however, that it was never so much the source of susceptibility of action which the physiologists of those days were in quest of—this being always at hand in the supposed vital principle—as that of the stimulus to action, in addition to that which the said vital principle supplied; but in as far as irritability is now known to be the only modification of nervous energy which the involuntary motions require, their chief stimulus to action being confessedly of a very different nature, if they derive any thing from the cerebellum, it can be only the property in question. More recently, also, M. Le Gallois, supported rather too hastily by Humboldt, Percy, and Hallé, in their report upon his experiments, (*Sur la Principe de la Vie*, 1812), has attributed a similar office, at least as far as the heart is concerned, to the spinal cord. But that the muscles, if not of voluntary, certainly of involuntary motion, were as independent, for either their susceptibility of

action, or their stimulus, of both the cerebellum and spinal cord as of the cerebrum, was known, not only to Glisson, but even to Galen; who, in placing his vital and natural spirits respectively in the heart and liver, while his animal spirits were placed in the brain, indicated sufficiently distinctly his knowledge of the independence enjoyed by all the organic functions of every department of that system which is subservient to the animal. It has been satisfactorily shown also by Haller and Wilson Philip, in their attempts to establish the muscular tissue as the immediate seat of irritability, as well as by Cruikshank (*Phil. Trans.*, 1795), Bichat (*Sur la Vie et la Mort*, 1802), Brodie (*Phil. Trans.*, 1810), Clift (*Phil. Trans.*, 1815), Wiltbank (*Philadelphia Journ.*, 1825), and many other experimenters, that all these organs—cerebrum, cerebellum, and spinal cord—may be either deadened by narcotic substances, or even destroyed or removed—provided this be not done so suddenly and so violently as to produce, as was done by Le Gallois, an irrecoverable shock on the whole system—without stopping, or even materially impairing the involuntary actions. The latter may indeed be effected through these organs, so long as they continue in action, as in the case of the passions, by which an inordinate stimulus is communicated; but they are not at all dependent upon them for either the susceptibility or the stimulus by which their regular and uniform performance is maintained.

general similarity in structure to the sensiferous system of nerves—particularly the central portions of the latter—which are confessedly the seat of the directly analogous property of sensibility. 11. The precisely similar effects, already alluded to, of certain agents applied respectively to parts possessed of irritability, as imparted to them probably by the ganglionic system of nerves, and to these central parts of the sensiferous system. And 12. The differences in the aspect and physical properties of the ganglionic nerves corresponding to the different character of the irritability of the organs on which they are severally distributed.

On each of these alleged testimonies then, in favour of the presumption that the ganglionic system of nerves is the primary seat of irritability in all the tribes of organized beings which are possessed of such a system, it seems proper—as the subject is of primary importance—to make a few remarks; and afterwards to state, and endeavour to reply to some of the principal objections which have been urged against it, and which may not have been already met incidentally in the previous observations (a).

(a) Before the time of Galen the ganglionic system of nerves was entirely unknown, and although by him and his followers, the Arabians, the existence of this system, as well as its supposed origin from the upper maxillary branch of the trigeminus nerve was pointed out (*De Nerv. Orig.*), as its other supposed origin from the abductor nerve was subsequently by Eustachi (*Tab. xviii, fig. 2*), it was not till the time of Willis that the ganglionic nerves were generally considered as a part of the nervous system at all. Willis however still looked upon them as merely an appendage to the cerebro-spinal system, and represented them, both in his verbal descriptions of them, and in his curious diagrams of their distribution, as growing upon the latter "*ut frutex super alio frutice*" (*Anat. Cerebri*, 1664); and this notion having been adopted by Vieussens (*Neurograph.*, 1684), Lancisi (*Op. Omu.*, 1745), Meckel, sen., (*Mem. de Berlin*, 1745), Zinn (*Mem. de Berlin*, 1753), Haare (*De Gangl. Nervorum*, 1772), Scarpa (*De Nerv. Gangl.*, 1779), Monro (*On the Struct. and Funct. of the Nerv. Syst.*, 1783), Blumenbach (*Inst. Physiol.*, 1786), Chaussier (*Exposition, &c.*, 1807), Le Gallois (*Sur la Principe de la Vie*, 1812), Bécларd (*El d'Anat. Gén.*, 1823), Wilson Philip (*On the Vital Functions*, 1817), Mason Good (*On the Study of Medicine*, 1825), and numerous other writers, both before and since the time that their independence was insisted on by Winslow, it has become a very prevalent custom to regard these nerves as of very secondary importance, and the names imposed upon the system in general, as well as the uses assigned to it, have generally corresponded with this idea. Thus by Scarpa as the cerebro-spinal ganglions, or those appertaining to the sensiferous nerves, are called simple, so those of the ganglionic system, properly so called, are designated compound, while by other authors, as the former are dignified by the appellations of primary ganglions, or ganglions d'origine, so the latter are sunk into secondary ganglions, or ganglions de reinforcement; and the whole system is pedantically described by Good as "an epicycle within the two cycles of cerebral and vertebral influence," and as "equally enriched

with the nervous stores of the brain and spinal marrow." (*Study of Med.*, 1825, vol. iv). With respect to the uses also attributed to this system of nerves under the same impression, the ganglions of the sympathetic nerve were regarded by Galen, their discoverer, as serving in the manner of buttresses, as it were, interposed at convenient distances, in order to strengthen the nerves as they receded from their reputed origin in the spinal cord or brain; and by Willis, on the one hand as a kind of diverticula of the animal spirits received from the brain, and, on the other—as the name so unfortunately given by him to this system of nerves implies—as a means of keeping up a sympathy between distant organs; and a similar opinion was adopted by Vieussens and Meckel. Lancisi, again, looked upon the ganglions of this system in the light of little forcing pumps, adapted to propel the said animal spirits along the nerves after the influence upon them of the dura mater—which, at this time, was regarded as a large muscle, serving to eject them primarily from the brain—was expended; and he accordingly describes them as furnished, for this purpose, with a proper muscular apparatus (*Morgagni Advers. Anat.*, part 5, p. 113). The rest of the authors who have adopted the notion of the subserviency of the ganglionic to the cerebro-spinal system, in particular Zinn, Scarpa, Monro, and Wilson Philip, have in general represented them as serving partly by the concentration within them of numerous nervous cords coming from the cerebro-spinal system to collect the so-called nervous energy—the old animal spirits—from various sources, and to transmit it afterwards in a more equable stream to the more important organs, and partly by the subdivision within them of these nervous cords, and the subsequent re-union of the filaments into other cords, to obviate the dangers which would have arisen had these organs received their nerves directly from only a few sources, instead of indirectly from several. Supposing, it has been said, that the heart or intestinal canal, for example, had received twenty nerves each directly from a distinct point of the cerebro-spinal system, and that one of these points

I. The universal distribution of the ganglionic system of nerves, although, at first sight, not very palpable, may very easily be inferred. It has, indeed, been the general practice

of origin had been cut off, it would have followed that a twentieth part of the organ would have lost the whole of its power, and disorganization and death must have ensued; but, from all these nerves previously passing through a ganglion, where they are so subdivided, and their filaments so re-united that every nerve afterwards proceeding from the ganglion contains more or fewer of the filaments of every nerve which enters it, if one of the points of origin be cut off, it follows, not that a twentieth part of the organ loses the whole of its power, but that the whole organ loses a twentieth part of its power, which is an accident of much less consequence. This hypothesis, unlike all those previously mentioned—which are unworthy of any serious attention—is so neat and pretty a one, that it is almost a pity that it is not well-founded. But it must be remembered, in the first place, that this appearance of certain nerves entering and others proceeding from a ganglion, and this in such a manner as that the latter are formed by the re-union of the separated filaments of the former, would equally result from *all* the nerves which are connected with a ganglion arising directly—as is in all probability the case—by minute filaments from the central parts of this organ, and proceeding in opposite directions; and, secondly, that the character of the influence communicated by the cerebro-spinal nerves, or those which are supposed to enter the ganglions, is known to be quite different from that which the proper ganglionic nerves, thus represented as directly derived from them, are known to impart. It could not, indeed, long escape observation that those organs which derived their nerves principally from the ganglionic system, unlike those which were furnished by the cerebro-spinal, were destitute of sensibility, and out of the dominion of the will, and it became, therefore, a necessary ingredient in all the hypotheses invented to explain the uses of the ganglions, that they served to intercept sensibility and volition, and to perform their part, as Willis says, “Cerebro inconsulto;” but, if their whole agency be as appendages to the cerebro-spinal system, in intercepting the only generally acknowledged properties and powers which are derived from the latter, what, it may be asked, have they left to communicate? The remarkable differences, also, in the structure of a ganglion and that of a mere plexus—the office of which really is probably to effect such an intermingling of the filaments of the cerebro-spinal nerves as has been above described—the abundance of grey matter which they contain—and which there is good reason to believe is always a primary source of some distinct faculty or power—

their frequently almost isolated situation, and the general want of correspondence in size or number between the nerves which are represented as entering and those which are said to proceed from them, all seem to shew that this, as well as all the other hypotheses, invented by authors who have presumed upon the secondary character of the ganglionic system, is untenable, and, as remarked by Magendie, “N'est qu'un jeu d'esprit.” “They teach us only,” as Sir Charles Bell observes, “what the sympathetic nerve is *not*, and by this means we are left to conjecture what really are its functions.” (Human Anat., vol. ii., p. 608.)

It was thus, then, from the circumstance of the ganglionic system of nerves not having been generally introduced to the notice of physiologists, till their minds were fully made up respecting the cerebro-spinal system as the only primary source of nervous energy, as it is called, that the real independence of the former—nay, in all probability, its rather serving as a foundation for the latter, since it is actually the first formed, than being engrafted upon it as an insignificant appendage—was overlooked, and facts were warped in support of prejudice and habit. Perhaps Winslow was the first to describe the ganglions of the sympathetic system as a kind of nuclei, or little brains, generating a peculiar property or power of their own (Exposition Anat. 1732, sect. 357—364), a description which was adopted by Le Cat (Traité du Fluide Nerv., 1765); but it was in the celebrated essay of Johnstone (On the use of the Ganglions, 1771), that the opinion that they are the primary source of irritability, was for the first time promulgated. It is true the promulgation of this opinion, like that of Willis, with respect to the cerebellum, and that of Le Gallois, with respect to the spinal cord, in this character, was indirect; since, as before remarked, it was not so much of the source of susceptibilities as of stimuli, that the physiologists have till very lately been in quest. Nevertheless, in asserting that the ganglionic system is to the involuntary organs what the cerebro-spinal is to the voluntary, Johnstone at least indirectly admitted the former as the primary seat of irritability, since this property is now generally acknowledged to be the only modification of nervous energy of which the involuntary organs stand in need. This doctrine, however, did not assume a precise and definite character till it was embraced by Pëffinger (De Struct. Nerv., 1784), and Reil (De Struct. Nerv., 1797), according to the latter of whom, “Perceptionem quædam habet istud systema; impressiones nempe recipit, et contra eas reagit; sed ista perceptio in proprio manet territorio, et cerebro laud communicatur”—

to describe the nervous cords which pass between the cerebro-spinal system of nerves and the ganglions of the great sympathetic, as the roots or origins of the latter, and those only

a definition of irritation, thus placed primarily in the ganglionic system of nerves, which differs from the original one of Glisson only in being much longer and much less elegant. The doctrine of the independence of the ganglionic system was espoused by Cuvier (*Leçons d'Anat. Comp.*, 1799), and particularly insisted on, with his accustomed eloquence, by Bichat (*Sur la Vie et la Mort*, 1802), who represented all the ganglions of this system as "*des centres particuliers de vie organique, analogues au grand et unique centre de la vie animale, qui est le cerveau*;" and who further demonstrated, not only that all these ganglions were collectively independent of the cerebro-spinal system, but that each ganglion was independent of every other—nay, that each nerve proceeding from such a ganglion was in a great measure independent of that ganglion, and even that each point of such a nerve was independent of all the rest, and constituted, *per se*, a distinct focus of nervous influence. Richerand (*Physiologie*, 1804), and Gall (*Anat. et Physiol. du Syst. Nerv.*, 1810), adopted similar tenets, and they are further inculcated by Wutzer (*De Corp. Hum. Gangl.* 1817), and Broussais (*Journ. Univ. des Sc.* 1818); the latter in particular describing the ganglionic system of nerves as possessing a peculiar kind of sensibility (*i. e.* irritability), with which it immediately endows all the organs destined for nutrition, secretion, and the other organic functions, and, by means of its repeated connexions with the cerebro-spinal system, all the organs of the body. By Bellingeri (*Dissert. Inaug.* 1818), a certain primary instrumentality in effecting all the involuntary motions is allowed to this system, although it must be confessed that this instrumentality signifies with him, not always irritability alone—or, as he calls it, organic sensibility—but sometimes a stimulus also, such as passion or instinct; and the same reproach of want of consistency attaches still more forcibly to Lobstein, one of the reputedly strongest patrons of the doctrine under consideration (*De Nerv. Sympath.* 1823). He has evidently a glimmering of the truth of this doctrine, since he describes the ganglionic system of nerves as presiding in general over the action of the heart, nutrition, secretion, and so forth; and, in speaking of the first, remarks that whereas, with respect to the voluntary muscles, the nerves, of one kind or another, convey to them uninterruptedly "their tone, strength, vital energy or characters and properties of animal nature"—all which, if it signify anything, signifies only irritability—and at intervals the stimuli by which they are excited to voluntary motion—in other words volition—with

respect to the involuntary muscles, the nerves convey to them in general the former alone, their stimulus being derived from other sources. Still as he appears to have no idea that different nerves are employed, in the former case, in the two processes alluded to—the irritability of the parts being derived, in all probability, from the ganglionic nerves with which they are supplied, while the stimulus is certainly conveyed by the motiferous—but attributes both to the cerebro-spinal nerves in general, so he seems to think that in the latter, while the irritability is always derived from the ganglionic nerves, the stimulus may, in some cases, be so too. He appears in short to have no distinct idea of the plurality of the nervous energy, as dependent upon the several departments of the nervous system, every nerve being with him, as with Mason Good and other physiologists of the same stamp, a nerve of all work according to circumstances, and engaged apparently upon the condition of making itself generally useful; and, from this defect of an asserted leading principle, his work, in the physiological part of it, is such a mixture of truth and error, that it is almost impossible to make any thing of it, and it has accordingly contributed perhaps very little towards establishing the doctrine which it is considered to advocate. Not so with that of Brachet (*Sur les Fonctions du Syst. Nerv. Gangl.*, 1823), who distinctly represents the ganglionic system of nerves as the seat of irritation, or, as he chooses to call it, "imperceptible sensation," and as presiding in an especial manner over the several viscera of the body. This is rather a loose and untangible way of expressing what is intended; but it amounts to this—that this system of nerves is adequate to effect all the functions to which irritability alone is essential, while others are requisite as often as either sensibility, the faculty of thinking, or the power of exciting voluntary motion, is called for. Mr. Parker, of Birmingham (*Medical Gazette*, 1831), Dr. C. W. Henry, of Manchester (*Ed. Med. and Surg. Journ.*, 1832), Dr. Lovell Phillips, of Bath (*On Inflammation*, 1833), and many other British authors, have recently adopted similar opinions; so that the doctrine above advocated may be regarded as certainly increasing in popularity even among a people who are almost as notorious for the pertinacity with which they cling to the effete tenets of their Whytts, their Monros and their Cullens, as the ancient Egyptians for their blind adherence to the precepts of the renowned Tot, or Hermes Trismegistus, the Chinese to those of Confucius, or the Persians to those of Zoroaster.

which pass between the ganglions and other organs as their branches; and hence it is a very prevalent impression that the distribution of the ganglionic nerves is extremely circumscribed and almost confined to the viscera of the chest, belly, and pelvis. We must remember, however, that the larger blood-vessels are everywhere directly supplied by these nerves, and that branches of the blood-vessels, carrying with them continuations of the same system, proceed to every organized point of the body—that is to say, to every point possessed of irritability (a); so that, even admitting that the description of the origins of the ganglions just alluded to were a true one, no objection to the doctrine which ascribes to the nerves of this system the source of irritability, founded upon their supposed circumscribed distribution, could be maintained.

(a) If this were not the case, what is called a palsy of any part of the body, that is to say a failure of the faculty of sensibility and of the stimulus of volition, would always entail a corresponding failure in the same parts of nutrition, secretion, and absorption. The latter class of functions how-

ever require only the faculty of irritability, which is not impaired in this disease, for their exercise, whereas sensation and voluntary motion require in addition other properties and powers, in the failure of which this disease consists.

Foreign Medicine.

Abscess communicating with the Colon.

M. A. BERARD showed the Anatomical Society a preparation he had taken from a woman that had been seized with hypogastric pains after labour, and in whom an abscess of the iliac fossa was suspected. The following was found on dissection. A large abscess commenced at the superior-posterior part of the left loin, between the colon and the abdominal parietes; this abscess had reached the hypogastric region, passing the iliac fossa, and the intestine being throughout situated outside of the peritoneum. An induration of the cellular tissue of the pelvis had stopt its progress just before the bladder; but the pus had made a passage towards the right iliac fossa, separating the peritoneum in the hypogastric region. From the right iliac region it had proceeded upwards along the median line as far as the umbilicus; there it had found a place immediately underneath the skin, had separated it all around the navel, the skin over which, however, was sound and adherent to the subjacent tissues. The progress of this abscess, therefore, a curve with the concavity looking upwards, and had risen in the right loin to an elevation corresponding to that which it had attained in the posterior part of the left loin. At this latter point, the abscess communicated with the descending colon by a rounded aperture which, on the side of the abscess, was surmounted by a soft, circular puffiness.

M. Berard asks what could be the origin of this communication: is it a lumbar abscess that by the erosion of its parietes, had found a passage into the intestine? or is it an ulceration of the intestine that had implicated the cellular tissue, and then determined the formation of an abscess? The whole internal surface of the great intestine was hard, un-

even, and ragged; its parietes were thickened throughout the whole circumference.

M. Tessier remarked that the supposition of a primitive abscess of the iliac fossa was precluded by the perfect soundness and vermillion colour of the iliac muscle, whereas in the abscess of that region it is considerably changed, softened, and as it were macerated in the pus.

Ligature of the Brachial Artery at the bend of the Elbow.

M. Graëfe thinks that the method of Hunter, however advantageous in general, ought occasionally to be deviated from. He has cited an instance in which the brachial artery had been wounded in bleeding. He did not see the patient till three days after the accident, at which time the arm was swollen, tense, of a livid red, and very painful when pressed. In this case the tumefaction of the member would have presented an insurmountable obstacle to the ligature of the artery at the usual place—the internal margin of the biceps. M. Graëfe therefore preferred operating at the bend of the arm, because there the jet of blood would serve as a guide to the artery, which was accordingly tied above and below the wound in its coats. The patient was dismissed cured at the end of a month.—*Gazette Médicale*.

Cancer of the Stomach without Tumour or Vomiting.

On opening the body of a person above 50 years of age, in whom neither swelling of the epigastrium, cardialgia, nor vomiting had been observed during life, but merely an entire disgust to food during a month previous to death, M. Ribes found a considerable schirrous induration of the small curvature of the stomach, with very distinct contraction of the two orifices, both of which were also indurated. There was no dilatation of the œsophagus.—*Revue Médicale, Février*.

A NEW PRACTICAL FORMULARY

OF HOSPITALS, OR A

Collection of Formulæ of the Civil and Military Hospitals of France, Germany, Italy, Great Britain and Ireland, &c., containing the Indication of the Doses in which simple Substances, magistral and officinal Preparations of the Codex are administered, the use of New Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M. D., and P. VAVASSEUR, M.D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M. D. &c. &c.

(Continued from p. 341.)

Resolvent Liniment. H. St. Ant.

Rx. Camphoræ, 3 ij;
Aquæ calcis, 3 ss.;
Olei olivæ, 3 iss.

Misc.

Camphorated Soap Liniment. H. of Germ.

Rx. Camphoræ, 3 ij;
Ung. basilici, 3 j;
Sapon. nigr. 3 ss.

Misc.

*Employed in lumbago.**Pommade of Camphor.* H. de la Mat.

Rx. Pulv. camphoræ,
Oxid. zinci, ā ā gr. iij;
Butyri recent. 3 iij;
Spermatis ceti, 3 ij;
Ceræ albæ, 3 iij.

Melt the greasy substances, and add while triturating the camphor, and the oxide of zinc.

Employed in certain diseases of the eyes, to prevent the eye-lids from adhering together during sleep. It should be spread upon pieces of fine linen, which are to be applied to the borders of the eye-lids, and kept there by a bandage.

Cerate of Camphor. H. Militaires.

Rx. Camphoræ, unam partem;
Cerat. simplic., decem partes.
Tere simul.

Cataplasm Antiseptique. Hot. D.

Rx. Camphoræ, 3 ij;
Cataplasm. lini, q. s.
Pulveris cinchon, 3 iv.

Misc.

Employed with success in simple and hospital gangrene.

[I employ the camphorated liniment with opium in pertussis, with great success—Vide Opium. T.]

ASSAFŒTIDA.

A very active excitant, which appears to have a particular influence on the nervous system. In large doses it irritates the intestinal canal; in smaller ones, its general action is antispasmodic. It is frequently employed with advantage in hysteria, hypochondriasis, and nervous colics. It is recommended as an emmenagogue and an-

thelmintic. Good effects have been obtained from its use in certain cases of amenorrhœa, and in affections dependant on the presence of worms.

[It is used in large doses in hysteria, chorea, epilepsy, and other nervous disorders. T.]

INTERNALLY. Gr. x 3ss in pills, or in an emulsion.

Teinture. P. ʒj—3 ij and more, in a potion.

Teinture Éthérée. P. Gutt. xx—xxx, in a potion.

Mixture of Assafœtida. H. of Eng.

Rx. Assafœtidæ, ʒj;
Aquæ menthæ, 3 ij.

Fiat mistura, cujus capiat cochl. mag. secundâ quâque horâ.

Mixture of Assafœtida. (Millar).

Rx. Assafœtidæ, 3 iij;
Ammonizæ acetatis, 3 j;
Aquæ pulegii, 3 ii.

Dosis cochl. mag. secundâ quâque horâ.

Pills of Assafœtida. H. of Germ.

Rx. Assafœtidæ, 3 ij;
Saponis amygdal, 3 j;
Olei fœniculi, m vi.

Fiat massa, in pilulas gr. ij distribuenda.

Compound Assafœtida Pill. H. of Eng.

Rx. Assafœtidæ, gr. xx;
Ipecacuanhæ,
Scillæ, ā ā gr. ij;
Aquæ, q. s.

Fiant pillulæ vi, ex quibus sumat unam vel duas ter quaterve in die.

Antispasmodic Pills. M. de Santé.

Rx. Assafœtidæ,
Potassæ nitratis, ā ā ʒij;
Extracti cinchonæ,
—— catechu, ā ā 3 ij;
Moschi, gr. xv.

Divide in pilulas gr. vi, quarum sumat ij—iv in die. The quantity may be increased if necessary.

Antispasmodic Pills. Hôt. D.

Rx. Assafœtidæ,
Gummi acaciæ, gr. ij;
Moschi, pulveris, gr. j;
Pulveris valerianæ, gr. viij.

Fiant pilulæ tres, in die capiendæ.

Pills of Assafœtida and Musk. Hôt. D.

Rx. Assafœtidæ, gr. xij;
Moschi, gran., gr. vi.

Fiat massa, in pilulas sex dividenda, quarum capiat unam vel duas quotidie.

Antihysterical Drops. H. of Germ.

Rx. Tincturæ assafœtidæ, 3 ij;
—— castorei, 3 jss;
—— opii, 3 ss.

Guttæ x ad xx sumendæ pro dosi in potione vel cyatho aquæ.

EXTERNALLY. In an enema 3j to ij.

Lavement of Assafoetida. M. de Santé.

Rx. Assafoetidæ, 3j;
Vitelli ovi, No. j;
Aquæ, 3vj.

Fiat enema.

Employed in nervous affections, hysteria, &c.

Fetid Enema. H. of Eng.

Rx. Assafoetidæ, 3ij;
Decocti avenæ sativæ, 3x.

Misce pro enemate.

AMMONIACUM.

An energetic stimulant, whose action resembles that of assafoetida. It is employed in asthma, derangement of the respiratory and digestive systems, chlorosis, hysteria, &c. It is also used in chronic pulmonary catarrh, as an expectorant. This substance is useful as an external application in the treatment of tumours, not inflammatory, white swellings of the articulations, scirrhus, &c. It enters into the composition of many plasters.

INTERNALLY. Gr. x—3ss in pills or suspended in a potion by means of the yolk of an egg.

Tincture. P. ʒj—3ss. in a potion.

Pilules balsamique or *de Morton.* P. Gr. vj ad xx.

Mixture of Ammoniacum.

Rx. Ammoniaci, 3ij;
Aquæ, 3viij.

Triturate the ammoniacum, gradually adding the water. The dose is from 3ss to j, in a mucilaginous potion.

[It should be sweetened, on account of its unpleasant taste. T.]

Lac Ammoniacum.

Rx. Ammoniaci, ʒj;
Oxymellis scillæ, 3ij.

Decoque ammoniacum cum oxymelle et adde,

Aquæ pulegii, 3vi;
Menthæ piperitæ, 3iv.

Misce: dosis cochl. mag. secundâ quâque horâ.

[This is an excellent remedy, combined with comp. tinct. of camphor, in chronic bronchitis or winter cough of aged persons. T.]

In pulmonary catarrhs.

Expectorant Potion. H. de la Ch.

Rx. Rad. polygalæ senegæ, 3ij;
Aquæ ferventis, 3ij.

Coque, cola et adjice,
Ammoniaci, 3ji;
Syrupi tolutani, 3i.

Fiat mistura, cujus sumat cochl. mag. secundâ quâque horâ.

In pulmonary catarrh not inflammatory.

Diuretic Emulsion. (Swediaur.)

Rx. Ammoniaci, 3ij;
Vitellorum ovari, No. ij.

Solve et adde,

Infusi radicis oreosæ lini, 3viij;
Potassæ nitratis, 3ij.

Dosis cochl. mag. sæpe in die.
In dropsies.

Pills of Ammoniacum. H. St. Ant.

Rx. Ammoniaci, ʒiij;
Pulveris scillæ, ʒj.

In pilulas xlvij divide, quarum sumat iv vel v quotidie.

To facilitate expectoration in chronic pulmonary catarrh. In large doses, these pills act as a gentle purgative.

Pills of Ammoniacum and Myrrh. H. of Eng.

Rx. Ammoniaci,
Myrrhæ, āā 3ij;
Aquæ, q. s.

In pilulas, xl forma, ex quibus capiat ij ad iv bis vel ter in die.

Pilules Fondantes. Hôt D.

Rx. Ammoniaci,
Pulveris, rhei, āā 3j;
Assafoetidæ,
Croci, āā 3ss;
Aloes, gr. x;
Saponis medicinalis, 3iij.

Fiat massa, in pilulas granorum iij distribuenda, capiat duas bis vel ter de die.

Pilules Fondantes. H. of Germ.

Rx. Ammoniaci, 3ij;
Saponis medicinalis, 3j;
Olei juniperi, gut. xx.

Divide in pilulas granorum ij, quarum sumat xij ad xv quotidie.

EXTERNALLY.

Resolvent Collyrium. H. of Italy.

Rx. Ammoniaci, 3ij;
Vitelli ovi, q. a.

Tere et adjice,
Tincturæ opii, gut. xxx;
Aquæ fontanæ, 3x.

Fiat collyrium.

[The liquor opii should be substituted for the tincture. T.]

Ammoniacum Plaster. H. of England.

Rx. Ammoniaci, 3vij;
Aceti scilliticæ, 3ij.

Misce.

GALBANUM, SAGAPENUM, and OPOPANAX, possess the same properties as ammoniacum and assafoetida. They enter into the composition of many officinal preparations.

VALERIAN.

A powerful general excitant, but whose action is principally on the brain, and which, in small doses, acts as an antispasmodic and tonic. It is employed with advantage in hysteria, epilepsy, certain cases of megrim and other nervous affections, hypochondriasis, and fevers presenting atonic symptoms. It is recommended as a powerful febrifuge.

[It has unjustly fallen into disuse in this country. It was formerly combined with cinchona, and used advantageously. Dr. Epps thinks it a very valuable remedy. T.]

INTERNALLY. Powder. $\mathfrak{D}\text{ij}$ — 3j , twice a-day, and gradually increased to 3iv , and even more.

Infusion, or Decoction. 3j — iv to Oij of water.

The *Infusion de Valériane*, of the H. de la Ch., and of the Hot. D., contain 3j to the same quantity of water.

Distilled Water. P. 3ij — iv .

Extract. P. $\mathfrak{D}\text{j}$ — 3ss , in pills.

Tincture. P. 3ss — j , in a potion.

Antispasmodic Powder. H. Militaires.

Rx. Pulveris valerianæ, 3j ;

———— cinnamomi, gr. xij.

Divide in chartulas sex in die capiendas.

The *Poudre Antispasmodique* of the Hot. D. contains 3j of valerian, and ij of cinchona. It is used in the same cases.

Bolus of Valerian. H. de la Mat.

Rx. Pulveris valerianæ, gr. xx;

Potassæ sulphatis, gr. ij ;

Syrupi aurantii, q. s.

Fiat bolus.

In spasmodic affections.

Pills given in Epilepsy. Hot. D.

Rx. Pulveris valerianæ, gr. xxx;

Castorei, gr. iv ;

Oxidi zinci, gr. xx;

Syrupi simplicis, q. s.

Divide in pilulas vi, in die sumendas.

Antispasmodic Electuary. (Swediaur.)

Rx. Pulveris valerianæ,

———— florum aurantii, $\mathfrak{a}\mathfrak{a}$ 3vi ;

Misce. Dosis cochl. min. bis vel ter in die.

Compound Infusion of Valerian. H. of Germ.

Rx. Valerianæ, 3ij ;

Aquæ ferventis, 3viij .

Macera, cola, et adde,

Aquæ cinnamomi, 3ij ;

Etheris sulphur. alcoholiz. 3ij ;

Liquoris anodynii Hoffm. 3ij ;

Syrupi simplicis, 3j .

Dosis, cochl. mag. singulâ vel secundâ quâque horâ.

Excitant Potion. H. Militaires.

Rx. Valerianæ, 3ijss ;

Aquæ, 3viij .

Coque ad dimidiam, cola et adde,

Tincturæ cinnamomi, 3ss ;

Syrupi simplicis, 3j .

Fiat potio, cujus capiat cochl. mag. secundâ quâque horâ.

Syrup of Valerian. H. of Germ.

Rx. Valerianæ, 3viij ;

Aquæ ferventis, Oij .

Infunde per horas tres, cola et adde sacchari, lbiv.

The dose is 3ss — j , in stimulant and antispasmodic draughts.

MUSK.

A diffusible stimulant and energetic antispasmodic. It is employed in typhoid fevers, and in those accompanied with ataxia, to combat nervous symptoms, such as delirium,

convulsive movements, &c. It is recommended in whooping cough, epilepsy, tetanus, hydrophobia, hysteria, and other affections purely spasmodic. Combined with ammoniacum it is employed with success to arrest the progress of gangrene. It is administered to children in the form of enema, in convulsions arising from dentition. It is not much used on account of its dearness.

[It is also very much adulterated. T.]

INTERNALLY. Gr. v— 3ss , in pills, or suspended in an emulsion.

Teinture. P. Gut. xv— $\mathfrak{D}\text{j}$, in a potion.

Teinture Éthérée. P. The same doses.

Antispasmodic Powders. H. of Germ.

Rx. Moschi, gr. xxxij;

Opii, gr. iv ;

Sacchari, 3j .

Divide in chartulas xij ex quibus sumatur una, singulis horis.

Pills of Musk. H. St. Ant.

Rx. Moschi, 3j ;

Oxidi zinci, 3ss .

Fiat pilulæ xxxvi, quarum capiat viij—x in die.

In the treatment of nervous disorders.

Antihysterical Pills. H. St. Ant.

Rx. Moschi,

Extracti valerianæ, $\mathfrak{a}\mathfrak{a}$ $\mathfrak{D}\text{j}$;

———— opii, gr. xij.

Divide in pilulas xvi.

Each pill contains gr. $\frac{1}{2}$ of opium, and $1\frac{1}{2}$ of musk.

Mixture of Musk. H. of England.

Rx. Moschi,

Gummi acaciæ,

Sacchari, $\mathfrak{a}\mathfrak{a}$ 3j ;

Aquæ rosæ, 3vj .

Sumatur 3j ad ij , secundâ quâque horâ.

The *Mixture Musquee* of the M. de Barté is composed of gr. xij of musk, 3ij of sugar, and 3ij of water.

Julep of Musk. H. of Italy.

Rx. Moschi, gr. xij;

Aquæ menthæ piperitæ, 3ij ;

Syrupi corticis aurantii, 3j .

Fiat mistura, cujus cochl. min. omni horâ diei sumenda.

Antispasmodic Potion.

Rx. Tincturæ moschi, gut. xv;

Aquæ destillatæ pulegii,

———— tilis, $\mathfrak{a}\mathfrak{a}$ 3ij ;

Syrupi aurantii, 3j .

Dosis cochl. mag. omni horâ.

CASTOR.

A stimulant and antispasmodic, employed with advantage in spasmodic affections, such as hysteria, hypochondriasis, nervous palpitations, convulsive hiccough, epilepsy, nervous asthma, amenorrhœa, when it depends on a spasmodic state of the uterus, &c. On account of its stimulating action, it is useful in typhoid, adynamic, and ataxic

(typhous) fevers, to restore the general strength, and to combat nervous accidents.

INTERNALLY. *Powder.* Gr. x— \mathfrak{D} j, and even 3j, several times during the 24 hours, in pills or suspended in a vehicle.

Teinture. P. Gut. x—xxx, in a potion.

Teinture Éthérée. P. The same doses.

Antispasmodic Powder. H. of Italy.

R_x. Castorei, gr. ij;
Magnesiæ, 3j;
Gummi acaciæ, gr. xij.

Fiat pulvis pro dosi.

Pills of Castor. H. of America.

R_x. Castorei, 3j;
Acidi succinici, 3ss;
Extracti gentianæ, q. s.

Divide in pilulas xxiv, de quibus sumat ij—vi in die.

Antispasmodic Boluses. H. de la Pit.

R_x. Pulveris castorei,
—— succini,
—— assafoetidæ,
—— valerianæ, ā ā 3 ss;
—— camphoræ, \mathfrak{D} j;
Syrupi succinici, q. s.

Fiat massa, in bolos granorum vi dividenda quorum sumantur vi ad viij in die.

A Sedative and Antispasmodic Potion. H. des Enf.

R_x. Tincturæ castorei, gut. xx;
Aquæ valerianæ,
—— pœoniæ,
Syrupi simplicis, 3 ij.

Fiat haustus, partitis vicibus, sumendus.

Antihysterical Potion. H. of Germ.

R_x. Tincturæ castorei, 3 ij;
Etheris sulphur. alcoholiz. 3j;
Aquæ melissæ, 3 vi;
Syrupi aurantii, 3 v.

Misce. Dosis, cochl. mag. secundā quāque horā.

EXTERNALLY. In enema, 3 ss—j, kept in suspension by means of gum acacia.

AMBER GREASE.

An energetic stimulant. Employed as an antispasmodic in neuroses, convulsions, adynamic fevers, &c. It is seldom used at present. It enters into several officinal preparations.

INTERNALLY. Gr. v— \mathfrak{D} i, in pills.

Teinture. P. \mathfrak{D} i—3 ss, in a draught.

Teinture Éthérée. P. Gutt. xij—xxxvi, in the same manner.

Powder of Musk and Amber Grease. H. of Germ.

R_x. Ambre grisæ, gr. xvij;
Moschi gran. gr. iij;
Olei cinnamomi, m ij;
Sacchari albi, 3 iij.

Sit pulvis, ejus capiat, gr. xij— \mathfrak{D} i sæpe in die.

Pills of Amber. H. of Germ.

R_x. Ambre grisæ,
Confect. aurantii,
Extracti cinchonæ,
Opii pulveris, sing. 3 i.

In pilulas gr. ij redige—dentur v—x tertiis horis.

These are considered powerfully aphrodisiac. (See *Aphrodisiacs*.)

Balsamic Tincture of Amber. (Dippel.)

R_x. Ambre grisæ,
Bals. peruvian. ā ā 3j;
Potassæ subcarbon. 3 iij.

Tere simul et adde,
Alcoholis rectific. 3 ivss.

Dosis mxv—xx. As an antispasmodic in the trismus of new-born infants.

ANIMAL OIL OF DIPPEL.

[This is obtained after the distillation of animal matters, especially hartshorn. Its chief ingredient is subcarbonate of ammonia. T.]

In large doses it is an active poison; in small quantities it is said to be stimulant and antispasmodic. It is seldom used at present.

INTERNALLY. Gutt. v—xx, in sugar and water.

COD LIVER OIL.

Stimulant and antispasmodic. Employed in Germany in gout, rheumatism, scrofula, &c.

INTERNALLY. One to three table-spoonsful twice a day. A cup of coffee, tea, or some aromatic infusion should be taken after it.

[This medicine is extremely disagreeable. It is much used at Manchester. T.]

EXTERNALLY. In frictions.

[Volatile Oil of Black Mustard. (Magendie.)

To obtain this oil, take 10 kilograms of good black mustard, add 50 or 55 of water, and introduce into an alembic. Distil and condense with water.

This oil is employed in frictions, is an excellent rubefacient, and acts almost instantaneously. "It is preferable to ammoniacal preparations. It possesses a strong, disagreeable odour." (*Magendie's Formulary*, Seventh edition. Paris, March, 1835).

I insert the following new remedy in this place, as it was announced after the preceding part of this Formulary was printed. T.]

[Lactic Acid. (Magendie.)

This is a solvent of aliments in the stomach, and is used by Magendie in dyspepsia and indigestion.

Lactic Lemonade.

R_x. Acidi lactici, 3 i—iv;
Aquæ fontis, Oj;
Syrupi simpl. 3 ij.

To be made into lozenges of half a drachm each, which are kept in closely stopped phials.

The lactic acid rapidly dissolves calculi of the phosphate of lime, which are white.

The lactates of soda, potass, &c., have not as yet been tried by M. Magendie; but he

recommends them to practitioners. (*Op. cit.* March, 1835).]

ORANGE LEAVES

Tonics, stimulants, and antispasmodics. In small quantities they are used in nervous affections, such as convulsive coughs, hysteria, &c. In large doses they are recommended in epilepsy. [Seldom used in this country. T.]

INTERNALLY. *Powder.* As an antiepileptic. \mathfrak{D} i— \mathfrak{z} i progressively, in boluses, or in the form of an electuary, with honey.

Infusion. As an antispasmodic. No. iv—x to Oij of water.

Decoction. No. xxx—xxxvi to Oij of water.

Infusion of Orange Leaves. Hot. D. and de la Ch.

R_x. Foliorum aurantii, \mathfrak{z} ij;
Aque ferventis, Oij;
Macerata et cola.

Dosis, cyathus ter quaterve indiæ.

ORANGE FLOWERS.

Slightly stimulating: much employed as antispasmodics.

INTERNALLY. *Infusion.* Pinc. i—ij in Oij of boiling water.

Distilled Water. P. \mathfrak{z} i—iv.

Sirop. P. \mathfrak{z} i ad ij.

Oil. P. Gutt. ij ad vj.

Confection. P. q. v.

MARSH-MALLOWS (FLOWERS).

Antispasmodic and slightly diaphoretic. They are in daily use in a great number of diseases, and especially in nervous affections.

[They are seldom employed in the British dominions. T.]

INTERNALLY. *Infusion.* Pinc. i—ij in Oij of boiling water.

The *Infusion of Marsh-mallows* of the H. de Paris contain \mathfrak{z} ij of marsh-mallows to Oij of water.

Distilled Water. P. \mathfrak{z} ij—iv, as an ordinary vehicle for antispasmodic and other potions.

Infusion of Marsh-mallows and of Orange Flowers. H. de la Mat.

R_x. Infusi althææ, Oij;
Aq. destil. flor. aurant. \mathfrak{z} ij;
Etheris sulphurici, \mathfrak{z} ij.

Misce.

Taken in small cupsful when hot.

The **ROOTS OF PRONY** were formerly considered as antispasmodics: they were administered in powder, in doses of \mathfrak{z} ss to j. At the present day they are not used. There is a *Distilled Water*, from the leaves of this plant, in the *Codex*, which is frequently used as a vehicle for sedative potions.

CAJUPUT OIL.

A stimulant and energetic diaphoretic, acting also as an antispasmodic. It is employed in neurosis of the stomach, hysteria

and other nervous disorders, chronic rheumatism, &c. It is used externally in frictions, to ease the pains in gout and rheumatism.

[It was used in the blue cholera, without success. T.]

INTERNALLY. Gutt. iv—viij, and even more, in sugar, or dissolved in alcohol, in a potion.

Stimulant Drops. H. of Germ.

R_x. Olei cajuputi, \mathfrak{z} ss;
—cornu cervi, \mathfrak{z} j.

Misce.

Guttæ v—xv ex cyatho aquæ sumantur.

Stimulant Emulsion. (Swediaur.)

R_x. Olei cajuputi, \mathfrak{z} j;
Mucilaginis acaciæ, \mathfrak{z} iij;
Aque, \mathfrak{z} iv.

Fiat emulsio, cujus sumatur cochl. min. pro dosi.

EXTERNALLY. In frictions, q. q. mixed with an equal quantity of olive oil.

YELLOW AMBER.

An excitant. It is said that it possesses antispasmodic properties. It is not much used at the present day.

INTERNALLY. *Tincture.* P. Gutt. x— \mathfrak{D} i, in a potion.

Essential Oil. P. Gutt. iv—vi.

EXTERNALLY. *Essential Oil.* P. In frictions on parts affected with rheumatism.

SUCCINIC ACID was formerly used as an antispasmodic: it is not much employed at present.

Sirop de Karabe. P., which is added to antispasmodic potions, in doses of \mathfrak{z} ij— \mathfrak{z} i.

HARTSHORN.

In large doses it is an active poison; in smaller ones it is a stimulant and antispasmodic. It is not much used at present.

[It is frequently employed in this kingdom in syncöpe, hysteria, and other spasmodic disorders.

INTERNALLY. Gutt. v—xv, in sugar, or in a potion.

CHAPTER XI.

MEDICINES EMPLOYED AS SEDATIVES OF THE NERVOUS SYSTEM, NARCOTICS, &c.

OPIUM.

IN small doses it diminishes sensibility and produces a state of calmness, which brings on sleep; in larger ones it acts as a stimulant, and exhilarates the intellectual faculties, but afterwards brings on general weakness and a disturbed sleep; in fine, in large doses it is a very violent poison, which acts principally on the brain. It is very frequently used to allay acute pain, to cause sleep, and to diminish sensibility in a number of cases, and especially in chronic dis-

eases. It is employed with advantage in diarrhoea and cholera maligna, neuralgia, &c.

[This medicine has been long employed to allay pain in chronic diseases, and is contra-indicated when there is cerebral affection or constipation. It is only of late years that its chemical composition was fully ascertained, and that its sedative and stimulant properties were explained. This substance and its sedative preparations are perhaps more generally employed than any other medicine in the materia medica. T.]

Subst. incomp. Ammonia, the carbonates of soda and potass, the oxymuriate of mercury, the nitrate of silver, the acetate of lead, the sulphates of copper, iron and zinc, the infusion of galls and of yellow cinchona bark.

INTERNALLY. *Opium purif.* or *Laudanum.* P. Gr. $\frac{1}{4}$ —ij.

Aqueous Extract. P. The same doses.

Extract prepared by Fermentation. P. The same doses.

Dover's Powder. P. Gr. v—x, and even more. (Gr. 10 contain gr. 1 of opium, and the same quantity of ipecacuanha).

Pilules de Cynoglosse. P. Gr. ij—vi, and more. (Gr. 9 contain gr. 1 of opium).

Theriac. P. Gr. xij—3ss. (3j contains a little less than gr. $\frac{1}{2}$ of opium).

Diascordium. P. 3ss—i. (3j contains gr. 6-7ths of opium).

Teinture. P. Gutt. vi—xx, in a potion. (24 gutt. weighing gr. 12, contain gr. 1 of opium).

Laudanum Liquide de Sydenham. P. Gutt. x—xx, in a potion. (20 drops weigh about gr. xv, and contain gr. 1 of opium).

Laudanum de Rousseau. P. Gutt. ij—viij. (Gutt. 7 contain gr. j of opium).

Sirup. 3ij—iv, in a potion. (3j contains gr. 2 of opium).

Compound Powder of Chalk with Opium.
H. of England.

Rx. Cretæ preparatæ, 3ij;
Cinnamomi corticis, 3j;
Tortmentillæ radicis,
Acaciæ gummi, ā ā 3vi;
Piperis longi fructus, 3i.

Separatim in pulvèrem subtilissimum tere dein adjice,

Pulveris opii, gr. xxxiv.

Dosis, gr. xij—3i.

In diarrhoea. Much used to stop purging dependent on dentition of children. (3i contains gr. $\frac{1}{2}$ of opium).

Sedative Powder. H. of Germ.

Rx. Opii pulveris, gr. i;
Potassæ nitratis, gr. xij;
Sacchari purif. 3ij.

Divide in chartulas vi, quarum sumat unam secundà quâque horâ.

Pills of Soap and Opium. H. of England.

Rx. Opii contriti, 3iv;
Saponis duri, 3ij.

Gr. v contain gr. i of opium.

VOL VII.

Thebaic Pills. H. of Edinb.

Rx. Opii pulveris, 3i;
Pimentæ baccæ, 3ij;
Extr. glycyrrhizæ, 3vij.

Soften the opium and the extract of liquorice with a little diluted alcohol, then mix and add the Jamaica pepper pulverized. The dose is from v to x grs. (10 grs. contain 1 gr. of opium).

Pills of Opium and Ipecacuanha. H. of England.

Rx. Pulveris opii,
—— ipecacuanhæ, ā ā gr. i;
Confectionis rosæ caninæ, q. s.

Fiant pilulæ ij.

Pills of Opium and Antimony. H. of England.

Rx. Opii pulveris, gr. ij;
Antimonii tartarizat., gr. i;
Theraciæ, q. s.

Fiant pilulæ iv, quarum sumat unam vel duas quotidie.

Sedative Pills. Hot. D.

Rx. Extracti opii,
Antimonii sulph., ā ā gr. ij;
Potassæ nitratis, gr. iv.

Fiat massa, in pilulas viij distribuenda quarum capiat ij ad iv in die.

Employed in certain rheumatic affections.

Anodyne Pills. Hot. D.

Rx. Extracti opii, gr. iij;
Camphoræ, gr. vi;
Syrupi simplicis, q. s.

Fiant pilulæ vi, de quibus sumat unam ad tres quotidie.

In certain cases in which there is insomnolence.

Confection of Opium. H. of England.

Rx. Opii duri, 3jss;
Piperis longi, 3ij;
Zingiberis, 3iv;
Carui seminum, 3vi;
Syrupi simplicis, 3iv.

Fiat confectio, cujus sumat gr. xij, ad 3ss pro dosi. (Gr. xxxv contain gr. i of opium).

[The formula of the Lond. Pharm. directs four times the quantity of the ingredients. T.]

Black Drop. H. of England.

Rx. Opii pulveris, 3ij;
Omphacii, 3xij;
Nucis moschatæ, 3iij;
Crocii, 3ss.

Coque et adde,

Sacchari, 3ij;
Spumæ cerevisiæ, cochl. min. ij.

Let these ferment for seven or eight days; filter and keep it in phials well corked.

The dose is from gut. ij to vj, in a potion. (Six drops are equivalent to 1 gr. of opium).

[The preceding formula is extremely inaccurate, as will appear by the following, which is the genuine prescription for the Black Drop, by the original inventor Edward onstall, a medical practitioner at Bishop's

Aukland. It was given by a relative of the family to the late Dr. Armstrong, of London, when he resided at Sunderland, and published by him in his work on Typhus, 1816.

"Take half a pound of opium sliced; three pints of good verjuice; one and a half ounce of nutmegs; half an ounce of saffron. Boil them to a proper thickness, then add a quarter of a pound of sugar and two spoonfuls of yeast. Set the whole in a warm place near the fire for six or eight weeks, then place it in the open air, until it become a syrup; lastly, decant, filter and bottle it up, adding a little sugar to each bottle." Though this remedy has been extensively employed by physicians for nearly a century and a quarter, (for it was introduced about the year 1716) and is still a favourite medicine, it never obtained a place in the London, Dublin, or Edinburgh Pharmacopœia. An attempt has been made by Mr. Battley to supersede it, by the liquor opii sedativus; and next by the Dublin College of Physicians in their pharmacopœia, 1826, (Acetous solution of opium); but I have never observed such uniform and beneficial effects from either of the proposed substitutes, as from that which both were intended to supersede. T.]

Sedative Looch. H. des Ven.

Rx. Laudani liquid. Sydenham. gut. xv—xxx;

Mucilag. acaciæ, ʒ v;

Aq. flor. aurantii, ʒ ij.

The dose is a table spoonful in the evening, and repeated until the desired effect is produced.

Potion of Opium. H. of England.

Rx. Tincturæ opii, gut. xx;

Aquæ menthæ piperitæ, ʒ v;

Aquæ, ʒ iij.

Fiat haustus, cujus sumat cochl. mag. singulis horis.

The mixture with opium of the English Hospitals, is composed of ʒ iij of water, ʒ i of the tincture of opium, and ʒ vj of peppermint water. The dose is ʒ ss—jss, twice or thrice a day.

Potion of Gum with Opium. H. de la Ch.

Rx. Mucilag. acaciæ, ʒ iv;

Syrupi opii, ʒ ss;

Misce, dosis cochl. mag. singulis horis.

Emeto-anodyne Mixture. M. de Santé.

Rx. Laudani Sydenham,

Etheris sulphurici, ā ā ʒj;

Antimonii sulphuret. gr. ij;

Syrupi simplicis, ʒ j;

Aquæ fontanæ, ʒ iv;

Dosis, cochl. mag. singulis horis.

As a sedative and expectorant.

Compound Looch. Hôt. Dieu.

Rx. Extracti opii, gr. j;

———— cinchonæ, gr. iv;

Camphoræ, gr. vi;

Emulsion, amygdalæ ʒ iv.

Sit mistura, de qua capiat cochl. ampl. urgenti tusse.

In catarrh, accompanied by violent or troublesome cough.

Theriac Medicine. M. de Santé.

Rx. Theriacæ, ʒjss;

Gummi acacæ. ʒ i;

Syrupi simplicis, ʒ j;

Aquæ fontanæ, ʒ vj.

Fiat mistura, cujus sumat cochl. mag. pro dosi.

Employed as a tonic and sedative.

EXTERNALLY. Gr. vi ad xij, and even more, dissolved in water, to be added to fomentations or to cataplasms.

Liquor Opii (Sydenham). P. In friction, and with water in fomentations, lotions, collyria, &c.

Collyre Opiacé. P. q. v.

Liniment with soap and opium. P. q. v.

(T. opii ʒ j, sap. amygdal. ʒ ss, ol. olivæ, ʒ ij).

Anodyne Collyrium. H. of Germ.

Rx. Extracti opii, gr. j;

Camphoræ sol. in ol. gr. ij;

Mucilag. mali cydoniæ, ʒ j;

Aquæ rosæ, ʒ ij.

Fiat collyrium.

Employed in painful ophthalmia.

Collyrium with Opium. H. des Enf.

Rx. Liquoris opii (Sydenham),

Croci, ā ā ʒ j;

Decocti lini ferventis, ʒ iv.

Macera et cola.

Used in the same cases as the preceding.

Another of the same Hospital.

Rx. Extracti opii, ʒ ss;

Aquæ, Oj.

Misce.

Employed in cases of ophthalmia, accompanied with great increase of sensibility.

The Collyrium with opium of the H. de la Ch. contains only gr. ij of the extract.

[The vinum opii of the former Lond. Pharm. was a valuable remedy in chronic ophthalmia, but the London College have substituted spirit for wine, and designate the preparation as formerly!! T.]

Sedative Gargle. (Swediaur).

Rx. Extracti opii, ʒ j;

Aquæ ferventis, Oj.

Misce et adjice,

Spiritus rectificati, ʒ j.

Fiat gargarisma.

Employed with advantage in painful ulcerations of the throat and tongue.

Collutoire Opiacé. H. Militaires.

Rx. Tincturæ opii, ʒ j;

Syrupi mellis, ʒ iijss.

Misce.

Employed in the same cases as the preceding.

Sedative Liniment. (Ryan).

Rx. Liniment camph. c. ʒ ij—iv;

Tincturæ opii, ʒ ij—iv.

Misce.

[I have used this liniment in frictions on the cheeks, nape of the neck, dorsal spine, and chest, in whooping cough, with great success; and also on the cheek during dentition and facial neuralgia from toothache in adults. It will be found beneficial in rheumatismal and neuralgic pains in different parts of the body. T.]

Narcotic Fomentation. Hôt. D.

Rx. Opii, 3 ij;

Aquæ, ℥j.

Fiat lotus.

Anodyne Cataplasm. Hôt. D.

Rx. Liqueoris opii (Sydenham), 3 j;

Cataplasmatis lini, ℥j.

Misce in usum.

Employed in cases of phlegmasia accompanied with acute pains.

Anodyne Liniment. H. de la Ch.

Rx. Extracti opii, 3 iij;

Unguenti althææ, 3 j;

Balsami tranquilli,

Olei amygdalar., ā ā 3 ij.

Fiat linimentum.

Used in frictions on painful parts.

Sedative Liniment. H. de la Ch.

Rx. Tincturæ opii, 3 iv;

Camphoræ, 3 ij;

Olei amygdal. dulcis, 3 ij.

Misce.

The *Liniment opiacé* of the same hospital contains 3 ij of laudanum and 3 iv of the acetate of lead, with the same quantity of the oil of sweet almonds.

Narcotic Liniment. Hôt. D.

Rx. Liqueoris opii (Sydenham), 3 j;

Balsami Fioravanti, 3 ss;

——— tranquilli, 3 j.

Misce.

Another narcotic liniment of the same hospital is composed of 3 ss of laudanum to 3 iv.

Liniment Opiacé. Hôt. D.

Rx. Liqueoris opii, 3 j—ij;

Olei olivæ, 3 iv;

Saponis medicinalis, 3 ss.

Misce.

The *Liniment opiacé* of the H. des Ven. does not contain the soap, but a double quantity of laudanum.

The *Liniment opiacé* of the H. des Enf. differs only from that of the Hôt. D. by the absence of the soap.

In the *Liniment opiacé* of the H. St. Ant. the laudanum is replaced by the same quantity of opium.

Pommade employed in Neuralgia of the Face.
H. de la Ch.

Rx. Opii, 3 j;

Plumbi subcarbonatis, 3 j;

Adipis, 3 ss;

Balsami tranquilli, q. s.

Fiat unguentum.

Frictions should be made with this pommade on the affected parts.

Pommade Opiacé. H. des Ven.

Rx. Pulveris opii, 3 j—ij;

Cerati simplicis, 3 iv.

Fiat unguentum.

Employed to dress painful wounds or ulcers, or as an unction upon certain pustules and venereal tumours.

The *Cerat opiacé* of the H. des Enf. contains 3 j of laudanum to ℥j of simple cerat.

Sedative Suppository. H. of America.

Rx. Opii, gr. ij;

Saponis duri, 3 j.

Misce.

POPPY CAPSULES.

Narcotics, possessing the same virtues as opium, but in a far less degree. They are employed in the same cases as that medicine.

INTERNALLY. *Decoction.* No. j or ij to Oij of water.

Extract of Poppies. P. ʒj—3 j, in pills.

Syrup of Poppies. P. 3 ij—3 jss, in a potion; 3 j is equivalent to gr. i of opium.

Calmant Potion. Hôt. D.

Rx. Syrupi papaveris, 3 j;

Aquæ flor. aurantii, 3 ij;

Mucilag. acaciæ,

Infusi pectoralis, ā ā 3 j;

——— tilisæ, 3 ij;

Syrupi simplicis, 3 ss.

Dosis cochl. mag. sæpe in die.

Much used in cases of violent pain in any part, convulsions, &c.

Anodyne Potion. Hôt. D.

Rx. Aquæ aurantii, 3 j;

——— melissæ, 3 iij;

Syrupi simplicis, 3 j;

——— papaveris, 3 ss—j.

Dosis cochl. mag.

The *Potion Calmante* of the H. des Enf. is similar to the above mixture.

EXTERNALLY. *Decoction.* No. ij—iv to Oij of water, in lotions, fomentations, local baths, &c.

Sedative Gargle. H. des Ven.

Rx. Papaveris capsularum, No. ij;

Seminum lini, 3 j;

Aquæ ferventis, 3 vj;

Syrupi mellis, 3 ij.

Fiat gargarisma.

Employed to calm pains which are present in certain cases of syphilitic angina, &c.

Sedative Gargle. M. de Santé.

Rx. Syrupi papaveris, 3 j;

Decocti amyli, 3 viij.

Employed in painful angina.

(To be continued.)

Résumé.

Traité des Hémorrhagies Internes De l'Uterus, &c. Par A. C. Baudelocque, M.D., &c. Bruxelles, 1832. *Treatise on Internal Uterine Hæmorrhages.* By A. C. Baudelocque, M.D., &c. Brussels, 1832.

(Concluded.)

HAVING given, some numbers back, a pretty full analysis of the first chapter of this valuable and practical work, we shall only have room to notice so much of the remainder as relates to points of particular importance or difficulty. In the last section of the third chapter we find some interesting remarks on the diagnosis of *utero-peritoneal hæmorrhage*—a case not of frequent occurrence, but of difficult detection when it does occur. When this accident happens during gestation, it is indicated by the symptoms attendant on large loss of blood, with violent pain in the abdomen, which at first is usually confined to a particular spot, but soon extends, and is accompanied with fainting, intermittent, and sometimes extremely rapid pulse, vomiting, pallor and coldness of the surface, speedily followed by death—previous to which the pain generally ceases. When the extravasation proceeds slowly, and there is time for inflammation to extend over the surface of the peritoneum, the diagnosis becomes very obscure from the union of symptoms of peritoneal inflammation with those arising from loss of blood.

An interesting case of this kind has been recorded in the memoir of M. Breschet.

— Fonchaux, a servant, aged 34 years, of fine stature, well made, and of a sanguineo-nervous temperament, was admitted into the Hôtel Dieu on the 21st of July, 1825. M. Dance, at that time a house-pupil, supposed from the appearance of the patient that she laboured under acute peritonitis. She stated that she had been married at the age of 18, and had borne three children before the age of 24. Her labours had been easy, and she had always enjoyed good health. For about three months the menses had been suppressed, but she was convinced that this was unconnected with pregnancy. At the menstrual periods she had experienced pain in the lumbar region, and uneasy sensations in the hypogastrium,

but her general health was not impaired. On the 20th of July she went about her ordinary avocations without any feeling of indisposition. Being sent on an errand at one o'clock, P.M., she was suddenly seized, on her way home, with pain resembling colic, succeeded by syncope, which continued for an hour. She was carried to a neighbouring house, where she recovered from the state of fainting, but remained pale and exhausted, with increasing pain in the abdomen. During the night she suffered great anguish, and was restless, but with occasional intervals of sleep. She had some vomiting, which, however, soon ceased, and did not recur. The bowels were confined, and the urinary secretion suppressed. There was a small discharge of blood *per vaginam*. A physician who was sent for merely prescribed a quieting draught.

M. Dance first saw her on the 21st of July, about two in the afternoon, at which time her physiognomy was that of abdominal disease. The face was pale, the surface cold, the eyes dull and sunk, lips livid, voice feeble, intellectual functions unimpaired; the abdomen was tumid and tender over its whole surface, particularly in the iliac regions; the pulse threadlike; tongue pale, and whitish in the centre; much thirst; no vomiting. In this case the tumid and painful state of the abdomen indicated acute peritonitis, but the sudden accession of such alarming symptoms in a young person previously in good health was not easily accounted for. Was the peritonitis secondary on a sudden perforation of the stomach or intestines, and effusion of their contents? No symptoms of disease in these organs had previously existed. Was the case one of abortion, which the patient desired to conceal? The suspicion that this might be the fact induced M. Dance to examine. The result was that he was convinced she was pregnant, but he observed that there was no blood on the end of the finger when it was withdrawn. He intended to empty the bladder, in order to examine the state of the uterus more accurately; but deferring this till his evening visit, he prescribed leeches and emollient fomentations. He had only just left the room when the patient expired.

On inspecting the body twenty-four hours

after death, the cavity of the abdomen, and especially of the pelvis, was found full of clotted blood: about five or six pounds of blood appeared to have been effused. Blood was also infiltrated between the layers of the mesentery and under the peritoneum. The details of an interstitial conception which was found to have occurred, are omitted by the author, as foreign to the immediate illustration of the subject.

The fifth and last chapter is on the treatment of which the prophylactic part constitutes the most important subject of consideration. Internal uterine hemorrhage sometimes occurs without apparent cause, or supervenes so immediately upon the cause, that art is of little avail in its prevention; but when symptoms of uterine congestion merely are present, active practice will often prevent further mischief. The following case occurred to Delamotte:—

A large window-shutter fell on the abdomen of a woman three months' gone with child, and occasioned violent pain, which was followed by a slight hemorrhage. It is singular that the patient found she lost more blood in the recumbent posture than when sitting or standing. She was therefore desired to avoid the recumbent position, but to keep perfectly quiet, and she was twice bled from the arm. The bad symptoms disappeared, she reached her full time, and was delivered of a healthy boy.

M. Baudelocque considers blood-letting particularly applicable in cases of internal hemorrhage occasioned by violence. The following is a case illustrative of its application.

Madame C——, 21 years of age, of a nervous and lymphatic temperament, was used to experience colic and renal pains at the periods of menstruation, which usually lasted five days. She miscarried twice during the first year after her marriage, in both instances at the twelfth menstrual term. Three months after the second abortion, conception again took place, between the 17th and 20th Nov. 1814. She immediately abstained from carriage exercise, sexual intercourse, and stimulating articles of diet. On the 9th Dec. she looked pale and hollow-eyed, her pulse was feeble and there was tension of the hypogastrium. These symptoms gradually disappeared af-

ter continuing five or six days. On the 7th Jan. she experienced some pain in the loins on the 8th, the whole surface of the body was discoloured, and the roots of the nails of a violet hue; the eyes were sunk, the extremities cold, the hypogastrium tumid and tense, and the pulse extremely small; the colic pains continued at intervals. M. Deneux ordered four ounces of blood to be drawn from the arm. The pulse rose, the temperature of the body became more equal, the pains and tension of the hypogastrium diminished and had disappeared by the following day. A repetition of the same symptoms took place on the 5th of Feb. Bleeding was again prescribed, but deferred at the instance of the patient's friends. On the 7th, she had, in addition to the former symptoms, a sense of weight about the rectum, pain in passing the urine, pain in the hypogastrium and oozing of blood from the vagina. The colic and lumbar pains increased, the os uteri was tumid and painful to the touch, and the parietes of the vagina were swelled, tender, and hot.

M. Deneux abstracted a small quantity of blood and prescribed entire repose, chicken-tea, infusion of linden-flowers, and emollient enemata. In consequence of this treatment she passed a good night, and next day was nearly as well as usual.

The same symptoms occurring in a minor degree were again obviated by venesection, and on the 1st July (being the eighth menstrual period) blood was again drawn for a pulmonary congestion. This lady was safely delivered at the full time, and has since borne two children without being bled during her pregnancy. Our author observes that too much blood should not be drawn at once, since he has seen many instances in which too copious venesection was fatal to the child—this result sometimes follows if syncope be induced, hence it is prudent to bleed pregnant women in a recumbent posture, to diminish the likelihood of fainting.

We regret that we cannot further extend our review of this very excellent work; the practitioner will find it to contain a great number of interesting cases in obstetrics, connected by highly judicious and practical observations.

The Surgeon's Practical Guide in Dressing and in the Methodic Application of Bandages. Illustrated by numerous Engravings. By Thomas Cutler, M.D., late Staff-Surgeon in the Belgian Army. 12mo. pp. 195. London: J. Taylor.

Few students or practical surgeons pay proper attention to the methodic application of bandages, though of great value in practice. The fault, however, lies with the professors of surgery, who scarcely ever notice the minor operations or mechanical means of their art. They seem to suppose that students are to learn the performance of the minor operations by intuition; while they forget the great responsibility incurred by the future surgeon in setting a broken limb badly, and incurring the infliction of heavy damages for such malpractice. The omissions of public teachers are at length being supplied by many experienced contemporaries of equal talent, though of less celebrity. We have now manuals on different branches of medicine, which contain as much, and indeed often more, than systematic works. The work before us is of this description. The author has collected his materials from the best surgical works, and from personal observation in the British and Continental hospitals. He has illustrated the proper application of bandages according to the regions of the body, and given wood-cuts of those of the head, neck, trunk, upper and lower extremities. There are 100 wood-cuts and four lithographic plates, illustrative of bandages, pullics, &c.

Dr. Cutler has accomplished his object in a very satisfactory manner. The work is a very valuable pocket manual to the student, the general practitioner, to the army, navy, and hospital surgeon. Moreover it is published at one-third of the price of the only other British work on the subject.

—o—

The Constitution of Man, considered in relation to External Objects. By George Combe. Henderson Edition. Price 2s. 6d. 12mo. pp. 446. Edinburgh: J. Anderson. 1835.

We give the price of this admirable work, as it is so moderate that every individual may possess it. It appears that a Mr. Henderson, a sincere phrenologist, left a certain sum "for the advancement and diffusion of the science of phrenology, and the practi-

cal application thereof," and recommended his trustees to publish a cheap edition of the work before us, "so as to be easily purchased by the more intelligent individuals of the poorer classes, and mechanic institutions. And I think it proper here to declare, that I dispose of the residue of my property in the above manner, not from my being carried away by a fit of enthusiasm, but from a deliberate, calm, and deep-rooted conviction, that nothing whatever hitherto known can operate so powerfully to the improvement and happiness of mankind, as the knowledge and practical adoption of the principles disclosed by phrenology, and particularly of those which are developed in the *Essay on the Constitution of Man* above mentioned." The trustees have accordingly assigned a sum for the publication of the present work in a cheap form, and faithfully fulfilled the intention of the testator. The ordinary selling price of this volume would be about six shillings, and it is now offered for half-a-crown. It is called the Henderson edition, to distinguish it from a separate, finer, and more expensive impression intended for sale to the general public; and those who desire to obtain the cheap edition are directed to order it by this appellation.

The author acknowledges that he lays no claim to originality, and that his materials have been employed again and again, by writers on morals, from Socrates down to the present day. The following extract places his claims before our readers.

"The only novelty in this *Essay* respects the relations which acknowledged truths hold to each other. Physical laws of nature, affecting our physical condition, as well as regulating the whole material system of the universe, are universally acknowledged, and constitute the elements of natural philosophy and chemical science. Physiologists, medical practitioners, and all who take medical aid, admit the existence of *organic laws*; and the sciences of government, legislation, education, indeed our whole train of conduct through life, proceed upon the admission of laws in morals. Accordingly, the laws of nature have formed an interesting subject of inquiry to philosophers of all ages; but, so far as I am aware, no author has hitherto attempted to point out, in a combined and systematic form, the relations between these laws and the constitution of man; which must, nevertheless, be done before our knowledge of them can be bene

ficially applied: nor has any preceding author unfolded the independent operation of the several natural laws, and the practical consequences which follow from this fact. The great object of the following Essay is to exhibit these relations and consequences with a view to the improvement of education, and the regulation of individual and national conduct.

"But although my purpose is practical, a theory of mind forms an essential element in the execution of the plan. Without it, no comparison can be made between the natural constitution of man and external objects. Phrenology appears to me to be the clearest, most complete, and best supported system of human nature, which has hitherto been taught; and I have assumed it as the basis of this Essay. But the practical value of the views now to be unfolded does not depend entirely on phrenology. The latter, as a theory of mind, is itself valuable, only in so far as it is a *just exposition* of what previously existed in human nature. We are physical, organic, and moral beings, acting under the sanction of general laws, whether the connection of different mental qualities with particular portions of the brain, as taught by phrenology, be admitted or denied. Individuals, under the impulse of passion, or by the direction of intellect, will hope, fear, wonder, perceive, and act, whether the degree in which they habitually do so be ascertainable by the means which it points out or not. In so far, therefore, as this Essay treats of the known qualities of man, it may be instructive even to those who condemn phrenology as unfounded; while it can prove useful to none, if the doctrines which it unfolds shall be found not to be in accordance with the principles of human nature, by whatever system these may be expounded."

The distinguished author has wisely avoided all religious controversy. He has imitated the brilliant examples of Dugald Stewart, Dr. Hutcheson, Dr. Adam Smith, Dr. Reid and Dr. Thomas Brown; and pursued their plans "with the new lights afforded by phrenology." He also desires it to be understood, that his observations are exclusively confined to man, as he exists in the present world. His work does not embrace "the interests of eternity." "These belong to the department of theology, and demand a different line of investigation. I confine myself exclusively to moral philosophy." It would be well if other phrenologists so limited their views, and not confounded mind and soul as they have done. Mr. Combe goes on to shew that his conclusions are those inculcated in the university of Cambridge.

"In 'A Discourse on the Studies of the University, by Adam Sedgwick, M.A. &c.' of which a third edition was published at Cambridge in 1834, the author remarks, that 'we are justified in saying, that, in the moral as in the physical world, God seems to govern by general laws.' 'I am not now,' says he, 'contending for the doctrine of moral necessity; but I do affirm, that the moral government of God is by general laws, and that it is our bounden duty to study these laws, and, as far as we can, to turn them to account.' 'If there be a superintending Providence, and if His will be manifested by general laws operating both on the physical and moral world, then must a violation of these laws be a violation of His will, and be pregnant with inevitable misery.' 'Nothing can, in the end, be expedient for man, except it be subordinate to those laws the Author of Nature has thought fit to impress on his moral and physical creation.' 'In the end, high principle and sound policy will be found in the strictest harmony with each other.'

"These are precisely the views which it is the object of the present work to enforce; and it is gratifying to me to see them so ably and eloquently recommended to the attention of the students of the University of Cambridge."

We have only room for the insertion of the contents of this delightful volume. These are—general view of the constitution of human nature and its relations, to external objects—on natural laws—on the constitution of man and its relations to external objects—on the sources of human happiness, and the conditions requisite for maintaining it—application of the natural laws to the practical arrangements of life—to what extent are the miseries of mankind referable to infringements of the laws of nature—on punishment—on the combined operation of the natural laws—influence of the natural laws on the happiness of individuals—on the relation between science and scripture—conclusion—appendix—natural laws—organic laws—hereditary transmission of qualities—laws relative to marriage and education in Germany—death—infringement of the moral laws. Here are subjects for meditation and reflection, which interest every rational individual. Moral philosophy is a science of deep interest to our profession, as well as to the public; and we strongly advise our junior as well as our senior friends, to study it in this comprehensive and splendid little work. Every member of the profession ought to possess it, phrenologists and anti-phrenologists.

The Pathology and Diagnosis of Diseases of the Chest. Illustrated especially by a rational Exposition of the Physical Signs, with new Researches on the Sounds of the Heart. By Charles J. B. Williams, M.D., &c. &c. Third Edition, much enlarged. Plates. 8vo. pp. 209. London: J. Churchill. 1835.

THE excellence of this work has secured it a large circulation. The author has arranged all that is known of auscultation in relation to diseases of the chest and heart, in a concise and perspicuous manner; and enabled the student and practitioner to acquire a perfect knowledge of these subjects with ease and pleasure. This work contains every conclusion and fact on the diagnosis of the diseases of the chest and heart in the last edition of Laennec; and published at nearly a third of the expense. The gratifying manner in which the former editions were received, has induced the author to revise the whole with the greatest care. He has also given a new version of the auscultation of the heart, and of the causes of the different sounds afforded by the chest. This work is in our opinion, the best on the subject in our language. It comprises many important facts discovered since the decease of the great Laennec; and should be a source of reference to every medical practitioner. We would, however, suggest to the able author, the necessity of including the auscultation of the abdomen as in pregnancy, of urinary calculus, &c., in his next edition.

—o—

Anatomical Description of the Parts concerned in Inguinal and Femoral Hernia, translated from the French of M. Jules Cloquet, with Lithographic Plates and a few additional Explanatory Notes. By Andrew Melville M'Whinnie, Assistant Teacher of Practical Anatomy at St. Bartholomew's Hospital. 8vo. pp. 48. Plates. London: Highley. 1835.

Few subjects are more important to the surgeon than the anatomy of the parts concerned in hernia, and we cannot be surprised at the great number of distinguished writers who have illustrated it. It is scarcely necessary to remind the reader that Mr. Guthrie has recently published new views of the anatomy of herniæ; and we know that Dr. Alexander

Thomson has been engaged for some years in the hospitals and anatomical theatres of Paris in preparing materials for a full history of this branch of surgical anatomy, to be illustrated by numerous engravings, which have received the highest praise from our Gallic contemporaries, and many of our countrymen. The essay before us is one of value, and should be placed by the side of Mr. Guthrie's recent work in the surgical library. It is well translated, and enriched by many instructive notes by Mr. M'Whinnie.

—o—

The London Medical

AND

Surgical Journal.

Saturday, April 18th, 1835.

INCOMPREHENSIBLE STATE OF THE PROFESSION.

OUR contemporary the *Lancet*, in last week's number, animadverts with much justice on the ignorance exhibited by the non-medical press of everything connected with the organization of the medical profession*, and attributes it to its true cause, the perplexing multiplicity of colleges and corporations, whose edicts, neutralising, confounding, and stultifying each other, form a mass of contradiction and absurdity equally embarrassing to the profession and unintelligible to the public.

We never could, even by the most laborious exposition, make any one of our lay friends comprehend either the subdivisions of the profession, or the constitution of those august bodies which legislate ostensibly *for*, and actually *against* it. Some things the public cannot be brought to understand, and others they refuse to believe. When, for instance, a man hears of fellows—candidates—ceptor candidates—licentiates—independents—pure surgeons—surgeons impure—surgeon apothecaries

* Some part of the *Lancet's* remarks have special reference to a particular journal, which ours have not.

—pure apothecaries; he at once gives up the natural history of doctors as a department of zoology too deep for persons of ordinary capacity.

Again, when we tell a non-professional man that the institution facetiously called the College of Surgeons consists merely of a council of twenty-two, which is self-perpetuating, and that many thousand persons who have past examinations, and paid heavy fees, to become *members* of this college, have no more to do with the college or its concerns than the Shah of Persia, he thinks we are making rhetorical flourishes, and will not believe that a thing at once so exceedingly comical and violently wicked can possibly exist in this or any other country.

A blessed state of things truly, in which folly is concealed by its complexity, and vice becomes incredible from its enormity!

But all this odious mummery, this vile compound of farce and iniquity, must and will fade away before the rapid progress of morals and intelligence. Everything now points to a consummation long anticipated by the clear-sighted, still derided by such as “ne’er look farther forward than their nose;” and most sincerely deprecated by those who derive emolument and importance from the perpetuation of an obsolete and corrupt system.

That consummation is the establishment of one Faculty of Medicine.

So desirable an event will not, however, immediately come to pass. The corporations are at present too much benighted to think of doing anything of the kind of their own accord, and compulsion, we conceive, is altogether out of the question; it would be no more compatible with law or justice to force them to coalesce, than it would be to marry two persons against their will: but the reforms which law, justice, and common sense imperatively demand, and which must soon be either voluntarily adopted, or unceremoniously

enforced, in the separate corporations, will so alter their spirit, that in a few years their coalescence will be their own spontaneous act. The Rhubarb affair at Blackfriars may be put out of consideration; it is, in effect, already null and void, it was sent into the air by a volcanic burst of laughter on the first rumour of a parliamentary inquiry. With respect to the colleges it may be observed, that *surgeon*-physicians are about to be admitted at Pall Mall; and, in spite of the half bullying, half skulking policy of the twenty-two in Lincoln’s Inn, *physician*-surgeons, that is, general practitioners, will ere long be obtruded, albeit as unwelcome coadjutors, into the counsels of the College of Surgeons.

Now, these changes being once effected, the coalescence of the colleges into one medical faculty cannot be delayed for many years. The foundations of the monkish system of medicine will be undermined; physicians will cease to be old women, and surgeons to be mechanics, and the science will rise on the ruins of the trade. The despicable collusions which now go under the name of “a good understanding among the different branches of the profession,” will cease to delude and injure the public; and young practitioners, who are now too often obliged to purchase success by the sacrifice of honour and independence, will find at least an open, if not a fertile field before them—the maxim will be, start fair and the devil take the hindmost: rather a selfish principle it must be allowed, but, nevertheless, the most equitable and the best that can be adopted in matters of public competition.

DR. HANCOCK ON THE PLANT CALLED
KOONUPARN.

*Abstract of a Paper read at a Meeting of the
Medico-Botanical Society, March 10, 1835.*

By the Secretary, Dr. Sigmond.

THE koonuparn is an elegant perennial shrub, indigenous to the interior parts of Guiana. The stem is jointed, and appears like that of cassader. It is usually planted in the provision grounds of the Indians, as they fancy it has a beneficial influence, and hence they often term it, *cassave mamu*. They employ it occasionally to catch fish; for, by bruising and throwing it into the water, the fish are stupified, presently float on the surface, and are taken by hand. It grows to about eight feet in height, and two inches diameter. The stem is jointed, extremely frondose or branchy. It flowers at all seasons of the year, and is constantly covered with leaves—yet it cannot be called an evergreen—for it has constantly a purple colour, or a mixture of green and purple. The foliation is peculiar. Its heart-shaped leaves are tern, or ranged in a most accurate, geometrical series in whorls; so placed, that each whorl, successively forms on the stem, a cord of sixty degrees with that next below; and below, the stems are marked with the vestigia of the fallen leaves.

Its white flowers stand in racemes at the summit of the branches. I have seen only the male plant, for this only has been brought from the interior, and planted by slips in the gardens on the coast. But I have been told by the natives that the fruit has the same form as that of the ricinus, or castor-oil bush. They affirm that one single seed operates as a powerful cathartic, carrying off amazing quantities of water, and thus they speedily cure great swellings, meaning dropsical tumours.

In the male flower.—The calyx is a cup, five-parted.

Corolla.—None.

Nectaries.—A nail or fleshy gland on the divisions of the calyx.

Stamina.—About forty in number; in five bundles, not connate, unequal, involved in a feathery or downy substance, which grows among the stamina.

Anthers.—Twin on each filament, round, red.

Pistillum.—Rudiments of the germ, three-sided.

Style.—Very short.

Stigma.—Six, divided.

The koonuparn or purple bush, seems much allied to the hynanche toxicodendron of Willdenow, but comes nearer, perhaps, to the Hecatea of Persoon. Indeed, I should think it a true species of this genus, although that eminent botanist, Dr. Hooker, has considered it identical with the euphorbia cotinifolia, and given it an accurate figure in his va-

luable work, the "Flora Exotica;" and if it be so, Willdenow's description is worse than useless. Indeed, the disparity is great, for I have compared it with the latter growing at Kew, the colour of which is pale green, and the other purple*. With all deference, however, to the learned professor's skill, I am fully persuaded they are distinct in species if not in genus.

This plant, in respect to its growth, and its sensible or physical properties, is one of the most remarkable, perhaps, of all the natural family of tricocca or euphorbiaceæ. The entire plant is replete with a lactescent fluid, of a pure white, and near the consistence of cream; and so copious is the juice as to trickle down in a small stream when an incision is made, or a branch broken. The fluid has a powerful acrimony, and when tasted, affects the mouth and fauces with a sense of burning, and the flavour of capsicum. Notwithstanding this acrimony, or rather, perhaps, in consequence of it, a tincture prepared from the dried and powdered leaves, forms the most efficacious medicine that I have ever met with. Four drachms of the powdered leaves are infused in six of proof spirit. Of this tincture from five to ten drops are given to the dose, and repeated every four or six hours.

Its sensible operation in a large dose, as twenty or thirty drops, will cause a great horriborismus, or rumbling of the bowels, which is soon followed by a rash or efflorescence like an *essera*, or rather diffused patches, with a slight but sensible elevation of the skin, first about the middle, then extending, more or less, over the whole surface of the body, at the same time attended with an itching or irritating sensation and sweat, and the internal inflammation in the meantime proportionately subsides.

From these facts this medicine evidently appears to act by producing revulsion, or by counter-irritation; giving the humours a tendency to distant parts to the whole surface of the body, and thus it appears to disburden the internal parts, suffering under excessive congestion and inflammation. In fact, a sort of temporary fever of a different kind is induced by this medicine, by which the internal irritation is transferred to the surface, and the vital parts are thus relieved.

But whatever may be regarded as the theory or *modus operandi*, I know of no re-

* I brought home the growing plant and deposited it in the Chelsea Botanic Garden, under the care of that skilful botanist, Mr. Anderson; where, I believe it is now in a thriving condition. The deep purple dye of its foliation was found to remain constant throughout the summer and winter, as Mr. A. informed me. I then presented a dried specimen of this plant to the Medico-Botanical Society.

medy possessing such powers against inflammations as this, and especially when employed in conjunction with moderate bleeding and the vapour bath. This I have seen proved on the coast of Essiquebo, and especially on the estate, Devonshire Castle, when a violent epidemic pneumonia prevailed, when patients in the last stage of the disease, and past all hope, were saved by this medicine, as will be remembered by the manager, Mr. E. Bunbury*.

Hospital Reports.

—
ST. GEORGE'S HOSPITAL.
—

Operations.—Extirpation of a large Tumour of the Mammary Gland.

APRIL 9th. A female, past the middle of life, was brought into the theatre, in order to have a large tumour removed from the left breast, the nature of which was doubtful. The tumour appeared to have commenced in the upper and outer angle of the gland, or that nearest to the axilla; it had reached the size of a child's head or more; its surface was of a regular smoothness throughout, and it was highly elastic on pressure; the skin covering it was of a delicate tenuity and very glabrous; through it could be seen numerous large veins, ramifying on the surface of the tumour.

Mr. Keate, who operated, commenced by making the two usual semicircular incisions over the tumour, so as to enclose an elliptical portion of skin on its surface; he then rapidly, with a scalpel, dissected out the tumour from the surrounding gland and adipose tissue, of which latter there was in this situation a rather abundant quantity. In effecting this, many of the nutritious vessels of the tumour, which were of sufficient size to bleed freely, were divided. Eight ligatures were applied, and the edges of the wound brought together with adhesive straps, in the ordinary manner. Compresses of folded linen were superimposed, and the whole secured, by means of a bandage encircling the waist and shoulder.

Upon a section of the tumour, it was found to be of a rather heterogeneous nature, containing a large proportion of adipose tissue, a serous cyst or two, whilst the greater part of it consisted of a tissue, apparently malignant, which alternated with the fatty portion of it. This ponderating element of the tumour was of a grey colour, and pulpy consistence, and was thought to be a modification of the medullary sarcoma of Mr. Abernethy, although it did not agree in every particular, either with that, or any other variety of malignant growths, included in that gentleman's classification.

* Dr. Wallace, the physician, who attended the estate, afterwards candidly told the manager, that these people were most unequivocally saved by this medicine.

Medullary Sarcoma of the Testicle—Castration,

Sir B. Brodie afterwards performed the operation of castration upon a man, who, scarcely more than a year since, had the other testicle removed, we believe at the Brighton Hospital, for a similar disease.

The tumour was of a regular ovoid shape, and about the size of a small cocoa nut; its surface was uniformly smooth, and had a very elastic feel on pressure; on its left side was a linear cicatrix, which indicated the seat of the previous operation. In order to confirm the diagnosis, Sir B. B. has on more than one occasion made a few exploring punctures, which gave issue to nothing but a few drops of blood.

A longitudinal incision was made over the tumour, which was then rapidly separated from its enveloping skin. The epididymis, which was quite healthy, was then divided just as it emerges from the external abdominal ring, Mr. Hawkins holding it, in order to prevent its retraction within the canal. The tumour having been, in this way, removed, the vessels of the cord were in the next place secured with ligatures, as were also a few bleeding vessels on the inner surface of the skin of the scrotum. The edges of the skin, none of which was removed, were brought together, a piece of lint having been previously interposed, and were kept in apposition by adhesive straps. A compress of folded linen was laid over the wound, which was kept in sit by means of a roller applied round the abdomen and thighs.

Upon making a section of the diseased testicle, it was found to consist of a tolerably homogeneous tissue, differing somewhat, as Sir B. Brodie observed, from the ordinary appearance of the medullary sarcoma, and indeed having a rather close affinity to the corresponding tissue in the diseased mamma previously removed by Mr. Keate.

Sir B. Brodie made a few observations upon the constitutional nature of the affections of which these growths are but the external and visible signs, and said, that according to his experience, in five at least, out of every six such cases, the disease reappeared in some other part of the body; very frequently, taking the course of the absorbents, it attacked the lumbar lymphatic ganglia; whilst in other cases the patient was cut off by its development in the tissue of the lungs.

—
Congenital Malposition of the Anus—Rectum opening into the Vagina—Operation.

A female child, scarcely more than a year old, was next brought into the theatre, having that form of congenital malformation, in which the rectum, instead of terminating by an external opening, or anus, in the perineum, opens on the posterior wall of the vagina, by which the fæces all constantly

passed; thus making a close approach to the permanent and normal condition of those vertebrate animals, which possess a cloaca, a general cavity into which the grand emunctories of the system severally discharge their contents.

The opening in the vagina was stated by the operator, Sir B. Brodie, to be of just sufficient size to admit the point of the little finger.

The operation to be performed, was to give the child an anus in the natural situation, and the following was done with this view. This will be found to be identical with the operation proposed by Chambon, as stated by Dr. Ryan, in his lectures on the Physical Education of Children, reported in his Journal (Vide No. for Jan. 16th). A curved director was passed by the vagina, through the opening of the rectum, into that gut, and was made to project in the perineum, in the normal situation of the anus. Sir B. Brodie, then cut down carefully upon the point of the director until he made it protrude through the skin; and he afterwards enlarged the opening thus made into the rectum, by cutting cautiously with a probe-pointed bistoury, to a little extent, at each of the four cardinal points. A piece of elastic gum catheter was then passed through this opening into the rectum, and retained there by means of tapes, which were connected to a bandage encircling the loins and thighs of the little patient.

Sir B. Brodie, in making a few observations upon the case after the operation, stated, that it was the only thing that could be done with any prospect of advantage, and that though he felt somewhat doubtful as to its successful result, yet that it was right to let the child have the chance of it. One reason which led him to doubt whether the operation would be of any avail, was, the uncertainty of the existence of any sphincter ani, and should this be absent, of course incontinence of fæces would be the result. In the event of its succeeding, it would be for a future operation, to close the opening into the vagina; but that, of course, must be deferred until the patient has attained such an age, as will, by the proper development of the parts, permit of the requisite manipulations; at which period, the operation by suture, for recto-vaginal fistula must be performed.

NORTH LONDON HOSPITAL.

Acute Inflammatory Dropsy.

SAMUEL NAGLE, labourer, aged 40, of intemperate habits, was admitted, March 9, under the care of Dr. Elliotson. Four years ago, he had swelling of different parts of the body, without any immediate previous illness. About eleven weeks since, he was seized with a violent pain in the back part of the head; and general œdema of the body took place.

The face was also much swelled; it is a singular circumstance that in acute inflammatory dropsies, the œdema begins in the upper extremities; whilst in those cases arising from weakness or obstructions, the swelling generally begins in the ankles, and extends upwards; the cause of this is owing to the difficulty the blood experiences in returning to the heart. The face swells in acute inflammatory dropsy, from its being exposed to heat and cold. He complained of cramps in the limbs, which is a common symptom, and attributes his illness to working in wet clothes; he has a short dry cough, with a slight expectoration of viscid mucus; you will generally find in acute inflammatory dropsy, that there is either pain in the head, or an affection of some of the cavities of the body. He has micturated scantily for four or five weeks; his urine has a violet odour, but its colour is natural; in general, patients do not make less water in this disease than when in health, and its colour is usually natural and without sediment; sometimes more water is made than the person is accustomed to. On examining the chest, we found the respiratory murmur very faint on the right side, and not very distinct in the course of the spinal column. There was not inflammation sufficient in any part affected, to warrant the necessity of blood-letting, but as there seemed a general tendency to inflammation, I ordered him to be bled to five or eight ounces, and gave him,

Rx. Potass. supertart. 3 ss;
Pulv. jalapæ, gr. x.

Statim.

And ordered him low diet.

With regard to the medicine, the supertartrate of potash does not act well alone, but is very efficacious, combined with a small quantity of jalap; a bitter aromatic is also beneficial, as it relieves the flatulence, which is often so troublesome in this complaint. The blood was slightly buffed, and the serum milky, his bowels freely opened by the powder. He has had a little giddiness, and his memory is slightly impaired; this is often a common symptom of giddiness.

19th.—He has been going on very well, having had two or three motions a day.

21st.—His body has increased in size—his urine is more scanty, there is a crepitous rattle distinctly heard in the left lung, and respiration is indistinct—there is also a slight crepitus on the other side. I ordered him to be again bled to 3 iv, and to take 3 i of the supertartrate of potash. I did not think it necessary to alter the method of treatment, but to increase the dose of the medicine.

25th.—He is much reduced in size, and appears to be going on very well. We shall soon be able to ascertain if there be chronic disease of any organ. Had this man lived formerly, it is most likely he would have

been ordered good living, and steel would have been given him, from the theory of the cause of dropsy then being, that it arose from debility. Now, we know that in general, it is dependent on increased action, instead of a debilitated one. In this disease there is generally great uncertainty with respect to the operation of diuretics, and this often arises from the kidneys being in a state of irritation, and when this is the case on the administration of these medicines, blood is often discharged. You will find venesection is sometimes the best diuretic, purging too is useful; or indeed anything tending to lower the system; or if it be a case attended with great weakness, two or three ounces of blood abstracted from the neighbourhood of the kidneys would be attended with benefit. We all know that stimulants and tonics do great injury in cases of very irritable stomachs, and so it is with regard to the kidneys if irritable, and diuretics are given; we may also instance too in fever stimulating diaphoretics do not increase the action of the skin.

In this case the chief circumstance to be noted is the simplicity of the treatment; in medicine as in surgery, the simpler the means we employ to relieve the patient, the better. It is said that in cases requiring the lancet, the urine will contain ablumen; but this is not the fact, there will often be a large quantity of ablumen present, and yet bleeding would be injurious. We have a case of general anasarca now in the hospital, where there is a great quantity of ablumen in the urine, and yet venesection would be improper.

—
Monomania.—Sedative Treatment, with Remarks by Dr. Elliotson.

Richard Carter, aged forty-six, was admitted under the care of Dr. Elliotson, a short time since. He had been deranged for some time; he has had syphilitic pains in the bones, which might have been the predisposing cause; he was despondent, and exceedingly apprehensive; he thought he was injured and ruined by others, that his constitution was destroyed by medical men, and he had great fears with respect to a future state; it was evidently a case of partial insanity.

Usually in cases of this description where there is no heat or tendency to inflammation in the part affected, the treatment is moral; to cheer the spirits of the patient has been considered the proper plan of proceeding. In this case there is no doubt that a particular portion of the brain was affected, though there was no pain; no flush of the face, but on the contrary a pallor, his pulse was low, no indication existing for bleeding, purgatives, or any species of antiphlogistic treatment. It has been found in cases of this description, that narcotics which do not irritate, have been highly beneficial; Dr. Seymour read a paper before the Royal Medico-chirur-

gical Society a short time since, in which he stated a great number of cases, which he had treated successfully by sedatives, in an establishment with which he is connected in Bethnal Green. This man was ordered half a grain of the muriate of morphia twice a day, it did him considerable good, and in a few days the deranged notions entirely left him. All the cases Dr. Seymour treated, were of partial insanity or monomania.

Opium, it is said, frequently stimulates, and is therefore unsafe for general use; but chemists have now so modified its different preparations that we can place great dependence on them. Whatever part of the brain is affected, the treatment will be the same.

—o—

WESTMINSTER HOSPITAL.

Eczema Impetiginoides.

SUSANNAH WEBB, aged 44, was received March 18th, into Percy Ward under the care of Mr. W. B. Lynn, having an extensive eruption of the right hand and arm extending above the elbow, and also affecting the left hand. She states that she had a similar affection six years ago, after her confinement, which was about seven weeks in being cured. Her last pregnancy was about four years since. The catamenia have been regular until about Christmas last, since which period their appearance has been irregular and their quantity diminished; they appeared twice in the same three weeks, and once within the last fortnight; indeed she appears to have attained to the climacteric period.

The eruption appeared on the ring finger of the right hand, about three weeks ago, in the form of vesicles, about the size of "small peas;" which contained a transparent fluid, and were attended with great heat, itching and redness of the integument. The vesicles at an early period broke and discharged an acrid and irritating fluid, leaving the surface of the corium denuded of cuticle; and suppuration was established from this surface. Poultices had been applied before her admission into the hospital, which might have some effect in modifying the character of the eruption. The whole of the right hand and arm as far as the elbow, to which the previous description alone applies, is highly tumefied and inflamed, being of a deep red colour, and very dry and rough from the partially present cuticle having a tendency to exfoliate in many parts of the surface, giving it the character of psoriasis. An ichorous pus is still secreted in many of the intermediate parts.

The eruption on the left hand, which did not appear until several days subsequent to that on the right, appears to have commenced in the form of psudaceous pustules, which have since increased in size and assumed irregular shapes. It would appear probable that the pustular form of the erup-

tion on the left hand has been occasioned by the stimulant application used since her admission into the hospital. It is, however, much less generally diffused than on the opposite limb, but in the form of patches more or less confluent; it extends up to the elbow. There is none of the tumefaction and redness, indicative of subcutaneous affection, as in the opposite limb.

The general health of the patient is very good, and there is no adequate cause to ascribe the disease to, except the derangement of the uterine functions. She has not been employed as a laundress, nor has she been exposed to the heat of the sun; neither have the digestive functions been in any respect impaired or disturbed.

The treatment has consisted in keeping the arm covered with flour, and in the occasional application of a lotion consisting of the following:—

Rx. Mellis anglic, ℥ iss;
Spirit vini rectif. ℥ ij;
Aque puræ, ℥ v. M. ft.

lotio.

She is also directed to have the warm bath every other night.

16th. She has had the warm bath once since last report, which she says has afforded her great relief. The heat and itching are both much diminished, as well as the secretion of glary pus. The application of the lotion she states to cause considerable pain at the moment. The pustular form of eruption on the left hand appears to be cut short by the treatment, and is now dying away. She has had a dose or two of the house physic. The flour is directed to be discontinued.

19th. The redness, tumefaction, pain, and other inflammatory symptoms are all rapidly subsiding in the right arm, the cuticle of which is undergoing a speedy desquamation, and only a trifling extent of secretion taking place in some situations. The eruption on the left hand has almost entirely disappeared, the pustules of which it is composed having dried and shrunk up. The lotion and bath are both continued, the first having the effect of increasing the pain, which, however, is materially alleviated by the latter. The general health continues very good, the bowels merely requiring to be regulated by the occasional exhibition of an aperient powder.

21st. A patch of eruption situate over the left elbow has passed into a rather active state of inflammation, there being redness and tumefaction, and also a secretion of an ichorous fluid. The right arm is rapidly approaching a complete state of cure.

25th. The catamenia have reappeared during the last few days in about as abundant quantity as usual. On this account the use of the bath is for the present suspended. The left elbow and the rest of the surface have continued to improve.

28th. The cuticle has now become almost

entirely removed by desquamation; and though a little roughness of the skin remains, yet the improvement is very marked. She has had two warm baths since last report.

April 8th. She is now so nearly well that she expects to leave the hospital in a few days.

—o—

Impenetrable Stricture, with Urinary Fistula. Operation.

Samuel Huie, æt. thirty. Eight years ago, while engaged as a planter in Jamaica, he fell across a beam, and injured his perineum: the accident was followed by retention of urine and extravasation. A small catheter was introduced thirty-six hours after the fall, and was kept in the bladder two days; the integuments and urethra had then sloughed, and laid open the passage several inches. It remained so twelve months, when the edges of the wound were pared, and ligatures applied. He wore a catheter till this had healed, which was in about two months. When it was withdrawn, the urethra became strictured at the same point, and at length almost impervious; only admitting the stilette of an elastic catheter. From this time he frequently suffered from retention of urine, and relieved himself by the introduction of the wire. About twelve months since, a small abscess formed in the perineum, behind the stricture, which burst, and the urine has been passed in part by the opening up to the present time. He was taken into the hospital, October 8th. No instrument could be passed through the stricture, except the small stilette, which he introduced with considerable dexterity. The urethra, at the termination of the bulb, was very hard and irregular, and behind it was a small opening in the perineum, which would scarcely admit the smallest probe. Micturition was attended with great pain; the urine passing guttatim from the fistulous opening, and in a minute stream, about the size of a horsehair, from the penis.

After he had been in the house some weeks, Mr. Key, finding it impossible to cure the stricture by dilation, proposed an operation, similar to the one which had before been performed, viz. that of opening the urethra with a knife, and allowing it to heal over a catheter. This was done on the 10th of November. The quilled suture was used, but removed three days afterwards, in consequence of a small slough appearing between the edges of the wound. A week after the operation the catheter was withdrawn, cleaned, and returned without difficulty. On the 10th of December, the opening was very small: Mr. Key introduced a smaller catheter, and ordered the Ung. Hyd. Nit. Ox. to be introduced on lint, with a probe.

On January 1st, the wound in the perineum was closed, except a very minute opening. The catheter was withdrawn, and ordered to

be introduced, when the patient wished to pass urine. The wound healed on the 12th; he introduced the catheter himself with facility, and was recommended to do so for some time, when he found it requisite. He left the hospital on the 17th.—*The Medical Quarterly Rev.*—April.

Case of Puberty and Pregnancy in a Girl of Ten Years of Age.—The following remarkable instance of this is related by Dr. D. Rowlett, of Kentucky, in our cotemporary, the *Transylvania Journal of Medicine* for October, 1834.

"Sally Deweese, daughter of John Deweese, was born in Butler county, Kentucky, on the 7th of April, 1824. She was of the ordinary size, but her hips and breasts began to grow rapidly in a few weeks after she was born, and at twelve months of age she began to menstruate, and her hips and breasts had become so large as to be the objects of common remark; and as she took no pains to conceal her condition, her menstruating so young became a fact of public notoriety, which continued regular till some time in the year 1833, when she became pregnant, and on the 20th day of April, 1834, she was delivered of a healthy female child, weighing seven and three-fourth pounds. Thus, at the age of ten years and thirteen days, she became the mother of a child of ordinary size; which, however, refused to suck her, and has been so far raised by the bottle. It is as healthy as is usual for children to be when raised from the bottle, and at the time of taking these notes it weighed eight and three-fourth pounds, and its mother weighed one hundred pounds. She was four feet seven inches high, and had the countenance of a girl not exceeding her in years, but is as intelligent as girls generally are at her age.

"She was the fifteenth child her mother had given birth to, and was born when her mother was forty-five years of age. There had been no previous case of early puberty, or premature old age in either the family of the father or mother.

"Her father lived in Butler county until she was two years old, and then removed to the place on which he now lives, in Hickman county, one mile south of Mayfield's Creek, and ten miles east of the Mississippi river, in latitude 36 deg. 59 min. N.; but I presume that latitude nor atmosphere has had any influence in this truly, (to me), astonishing case. I think it is an over-match for the case of the Swiss girl spoken of by Haller."—*American Journal of the Medical Sciences.*

Ointment to Allay the Irritation of Hemorrhoidal Tumours.—The following ointment is recommended by Dr. Geddings in our esteemed cotemporary, the *North American Archives of Medical and Surgical Sciences*, No. 1, as affording great relief to the irritation of hemorrhoidal tumours:—*Rx.* Pulv. carb.

plumbi. $\frac{3}{4}$ ss.; sulph. morph. gr. xv.; ung. stramon. $\frac{5}{8}$ j.; ol. olivar. q. s. Ft. ung. part. applicand.

Powdered opium to the amount of a drachm may be substituted for the morphia, and if the dry white lead is not at hand, that which is ground in oil for the use of painters may be advantageously substituted. Sometimes a drachm of powdered galls may be added.—*American Journal of the Medical Sciences.*

Extract from Resolutions of the Court of Assistants of the Society of Apothecaries.

RESOLVED, that the Society's garden at Chelsea be open every Monday and Friday from the middle of April to the middle of August, from nine o'clock in the morning until twelve at noon, and that admission be given to all such medical students as are pupils to the established professors and lecturers in the metropolis, whether upon medicine, chemistry, materia medica, or botany, and also to the apprentices of the several members of the society.

That during each season there be delivered, at the garden, lectures, and demonstrations upon one or more of the following subjects, so as to form a regular course of botanic study, namely:—

1. The different systems of botany, both natural and artificial.
2. The structure and growth of plants.
3. The different parts of plants, with their descriptions and uses in the process of vegetation.
4. The natural and chymical analysis of vegetable matter.
5. The medical uses of the most important articles in the materia medica, with observations on the best modes of preparing them.

That the conducting these demonstrations and lectures be committed to the society's professor of botany.

That in order to give encouragement to diligence and talent, there be an annual examination of such students as may think proper to become candidates for the prizes intended to be given on these occasions. The examinations to be upon some or all of the subjects stated in the foregoing series of lectures, as well as upon their skill in the nomenclature of plants. No person to be admitted a candidate who has not attended these lectures and demonstrations at least eighteen days in one summer, or thirty days in two succeeding summers, nor shall any prize be awarded unless this examination be performed to the complete satisfaction of the examiner or examiners for the time being.

To prevent partiality or undue preference, no public professor or lecturer, whose pupils are admitted to the garden, can be appointed an examiner.

The apprentices to members of the society,

having an annual opportunity of being candidates for prizes upon the ancient establishment, cannot be admitted candidates on these occasions, either during the period of their apprenticeship, or subsequently to the conclusion of it.

That two medals, the one being gold, of ten guineas value, and the other of silver or bronze, be annually awarded to the two candidates, who shall have passed the best and second best examination in manner hereinbefore mentioned, but no medal is to be given unless in the opinion of the examiner or examiners the candidates shall be deemed deserving of it.

The beadle, or some proper person, is to attend at the garden, on each day of admission, to receive the visitors, and to enter or cause their names and the names of their tutors to be entered regularly, in a book to be provided for that purpose, and also to note therein any misconduct or breach of established regulations which may come to his knowledge during such attendance, giving information thereof to the master and wardens.

That the following be the regulations for the admission of students:—

"It is intended that admission shall be given to all such medical students as are pupils to the established professors and lecturers in the metropolis, whether upon medicine, chemistry, materia medica, or botany; such students to apply at least three days prior at the beadle's office, in Apothecaries' Hall, for tickets of admission for that purpose, which the master and wardens will grant to such persons as they may think proper.

"In order that the master and wardens may be enabled to exercise suitable discretion in granting such tickets, each student must leave with the beadle a letter of recommendation from his tutor, stating that such student has been attentive to his studies, and is, in his opinion, desirous of improving himself in the science of medical botany.

"That a ticket be given to each student, and that such ticket be renewed annually."

By order,

ROBERT B. UPTON,
APOTHECARIES' HALL. CLERK.

The Medical Reform Bill.

A PARAGRAPH has gone the round of the newspapers stating that the magna charta of the medical profession is to restrain general practitioners from supplying medicines, and in lieu of which, they are to receive from five to ten shillings a visit. There is no truth in this rumour, and we speak advisedly when we state, that no report of the evidence given before parliament is yet complete; and consequently that no draft of a bill could be prepared until the report was presented to the house. Our brethren need not be alarmed at the intended enactment, for they may rest assured, that there is not one member of the

legislature, be he whom he may, so competent to manage the medical reform bill as Mr. Warburton, or to frame one more for the protection of the profession and the public.

Who is to operate for Cataract on His Royal Highness the Duke of Sussex?

Suum cuique.

THE *Portsmouth Cholera Gazette*, alias the new periodical, which assumes the title of this journal, has answered the above question thus—"Miscellany of facts. We understand that Mr. Alexander will not operate on His Royal Highness the Duke of Sussex; but that the eminent surgeon and oculist, Mr. Guthrie, has been engaged for that purpose." This is what Cullen called a false fact. We have it on the best authority that Mr. Alexander is to operate, and that Mr. Guthrie has not been consulted about the royal patient. It would be well if veracious periodicals misnaming themselves medical, should attend a little more to truth, and not one day kill a number of convicts at Portsmouth with cholera, when the disease was absent, and another deprive an eminent surgeon of the highest honour he possesses, by awarding that to another, who, though among the ablest, has yet to attain it.

Liability of Hospitals and Dispensaries to Poor's Rates.

A DECISION was given some time since by the magistrates of Hatton Garden police office against St. John's hospital and a rival institution in the same parish—the British St. John's hospital, for poor's rate. The parties gave notice of appeal to the sessions, and having neglected to carry their intention into effect, the magistrates ordered them to pay within fourteen days.

The hydra of taxation will not even exempt public charities or medical societies from its iron grasp, while it is lenient towards the halls and palaces of the aristocracy and the great ones. The time however rapidly approaches when such monstrosities will be exterminated.

LECTURES
ON
MEDICAL JURISPRUDENCE,
DELIVERED BY PROFESSOR A. T. THOMSON,
F. L. S.,
At the University of London; Session 1834-35.
LECTURE XXVI.

Sudden Death.

GENTLEMEN—That man is born to die, is a truth which every hour's experience impresses upon the minds of mortals. But, when death approaches the sick bed; when he lays his freezing hand upon the heart of the aged, or arrests the course of mortality, in any of the thousand ways in which he usually secures his victim, the attention and interest of those not closely connected by ties of blood or friendship with the sufferer, are scarcely roused; the event recurs and passes unheeded and unregarded. On the other hand, when the power of death is displayed, without any evidence of the manner of his approach; when a dead body is found in the street, or on the highway; when a person, who was in good health at night, is discovered as a corpse in the morning; or when the debt of mortality is paid in any sudden or unexpected manner, then immediately curiosity and interest are awakened, and every circumstance is investigated that can tend to throw the faintest gleam of light upon the event. In most civilized countries, however, this inquiry is not left to chance, but devolves upon an officer legally appointed, whose duty it is to examine every circumstance connected with all cases of sudden or suspicious death. In England this officer is denominated Coroner, *Coroner*, from his duty in pleas of the crown; the mode of electing a coroner, and his duties; the power and authority which he possesses of calling together a jury, and summoning before him professional men. When their evidence is required, or when the least uncertainty exists respecting the cause of death, a dissection is necessary. The evidence which the coroner receives is upon oath, and upon the decision in his court the

VOL. VII.

cause of death is recorded, and, if murder be suspected, those upon whom the suspicion falls are immediately arrested, and at a proper time put to the bar on trial for felony. The evidence, therefore, which a medical man is called upon to deliver before a coroner's jury, is not to be lightly considered.

Let us suppose a case of sudden death to occur, and that any one of you be called upon to examine into the causes of it:—a question arises, in what manner are you to conduct yourselves on such an occasion? In the first place, if the corpse be found in the field, in the highway, or in the street, you must divest your minds of every idea of murder, or suicide, or any unfair means having been the cause of death, until it be made so obvious as to admit of no doubt. You must examine, before the body is touched, if it have not been already moved, the position in which it lies, whether that indicate a fall from sudden insensibility or vertigo, or whether it lead to suspicion that the person had been beaten or knocked down. If any instrument be in the hand, or lying near the body, its nature and the position in which it is found lying, in reference to the body, must be noted down, as the presence of an instrument of death near a dead body, affords no evidence that that weapon had been employed as the cause of death, either by the person himself found dead, or by the hand of another. The state of the ground must, also, be carefully examined, whether blood be spilt upon it, and if so, whether it lie in a pool near the body, or can be traced from a distance; whether the ground bear the mark of a struggle having taken place, or only display the impression of the fall of the person. In fact, every particular relating both to situation of the place where the body is discovered, as well as the condition in which it is found, are properly expected to be noted down by the medical witness, both, because he is more able to make observations than the common crowd which usually collects on such occasions; and, also, because he is called upon to determine respecting the death of the person and must necessarily be a witness, in whatever court the cause of the death may become a subject of in-

C

quiry; and, also, because he is supposed from his superior knowledge and education to proceed to the inquiry with a mind freer from prejudice than the less instructed. After having made these observations, the body must be removed into a house, stripped, and carefully examined, to ascertain the presence of wounds or bruises. If any be found, its length, breadth, and depth, must be noted, as well as its condition, with regard to hæmorrhage, inflammation or gangrene; whether it be recent, whether a bullet or any other foreign body be present in it, and with what description of instrument it has been inflicted; whether a cutting or stabbing weapon, or such as can only injure by a blow. The extent of the wound must be traced, in the manner I lately described to you, and what nerves, blood-vessels, or viscera, have been penetrated. The dissection, under every circumstance which may have contributed to death, must be conducted with the utmost care and precision in the manner I pointed out to you, when treating of wounds; and I would further refer you for information on this subject to the third volume of Fodéré's valuable work on Legal Medicine, and Deare's Remarks on Medical Jurisprudence.

If the sudden death take place in a house, or a room, in the presence of others, the extent of inquiry becomes more limited; but if no person have witnessed the death, the same inquiries are requisite as if the body were found in the fields. It is felonious to bury a body which has died suddenly, before an inquest be taken. (Russell, p. 416.)

Before proceeding to notice in detail the causes of sudden death, whether arising from internal causes, or external causes, whether accidental or intentional, in which I comprehend both murder and suicide, it may be proper to remind you that persons may appear dead who are actually not so, and consequently, that in every case of supposed sudden death, the first object is to ascertain that the person is really dead.

There are various states into which the body may fall, which closely simulate death:—syncope, and that singular disease to which I have already had occasion to allude under the name of catalepsy, eclampsia, concussion, strangulation, suffocation, drowning, cold, intoxication, and mephitism: all of which may terminate in actual death. I shall notice each of these in detail; but let us first inquire what are the signs of death.

There can be no doubt that in warm climates, in Ireland and some other countries in which early interment is customary, and in periods of epidemic and infectious diseases, persons have been prematurely committed to the grave, in whom although there was apparent death, yet life still remained. In this country, therefore, and in many others, the rites of sepulture are deferred until putrefaction, the unequivocal test of the total cessation of every function of life,

begins to display itself. Numerous well authenticated cases of apparent death might be mentioned; but not to occupy your time unnecessarily, I will mention a few only. Diemerbroeck, in his work, *Tractatus de Peste* (lib. iv. sect. 85), states that a peasant who had apparently died of the plague, and had discovered no signs of respiration after three days, on being carried to the grave recovered and lived many years afterwards. Howard the philanthropist, in his work on Prisons, mentions that he has known instances where persons supposed to be dead of the gaol fever, and brought out for burial, on being washed with cold water, have shewn signs of life, and soon afterwards recovered. One of the most heart-rendering accounts of premature interment that I know, refers to one of the family of Clopton, of Clopton Hall, near Stratford on Avon. A contagious fever was carried into the family and attacked one of the daughters and a son. This young lady apparently died, and was deposited in the family vault, at Stratford, on a bier, as was the custom of the period in the time of Elizabeth, in great families who had vaults. About a week or ten days afterwards, her brother actually died; and, on opening the vault, to prepare for his interment, the unfortunate lady was found sitting on the steps of the vault, having risen from her bier and died, if not of the horror which her situation must have excited, of starvation. Perhaps some of you know the anecdote in the History of Vesalius, the celebrated anatomist, regarding the dissection of a Spanish gentleman, in whom on opening the thorax, the heart was found still pulsating. The unfortunate philosopher was brought before the inquisition, and but for the intercession of Phillip the Second, to whom he was physician, would have been condemned to death. He expiated his unintentional offence by a journey to the Holy Land; and in returning, was shipwrecked on the island of Zante, where he died of hunger. M. Bruskier, a French physician in the seventeenth century, relates a case, on the authority M. l'Abbé Menca of a young woman who was restored from apparent death by the first incision of the anatomist's scalpel, and lived many years afterwards. Enough has been detailed to shew the necessity of not pronouncing hastily on the presence of death, until the last unequivocal sign presents itself. At this juncture, the state of collapse which occurs in cholera, bears in many instances the closest similitude of death; and in a less enlightened age, might add many instances to those already too numerous tales of horror, of hasty and inconsiderate entombment of the living. Those who are desirous of perusing extraordinary relations of this kind, may be amply satisfied in the article *Premature Interment*, in the *Encyclopædia Britannica*; in the works of Diemerbroeck and Hildanus; and in the "*Dissertation sur l'Incertitude des*

Signes de la Mort et l'abus des Intermens, et Enbaumemens precipite, of John Bruhier, published in 1742. Many of the accounts of this description are, undoubtedly, fabulous; but it is impossible to deny that such instances have occurred.

The first of the signs of death is the suspension of respiration, and of pulsation in the heart and arteries. The suspension of respiration is the most certain of these, and it cannot be continued many minutes without actual death supervening: whereas the action of the heart and arteries may be suspended for a considerable time, if respiration be still carried on, however obscurely, and yet these organs be again awakened to activity. But when respiration ceases, nothing can again rouse the function of these organs, the irritability of the heart depending solely on the due oxidizement, or change of the vital fluid from venous to arterial blood; so true is the Scriptural phrase, that "life is in the breath." The first object, therefore, in supposed death, whether occurring suddenly or from lingering disease, is to ascertain whether respiration still continues. This can, in many instances, be perceived by baring the thorax and abdomen; for it is impossible for breathing to be carried on many seconds without the influence of the respiratory muscles, the effect of the action of which is to elevate the ribs and depress the diaphragm, so as to push forward the sternum and cause a momentary swelling of the abdomen. It is of great importance to the young practitioner to accustom his eye to judge accurately of these movements, as the ordinary methods of applying a mirror to the mouth, or a downy feather near it, are both liable to error. If the mirror be warmer than the expired breath, no sign can be obtained by it, because the breath is not condensed upon it; or the insensible perspiration from the hand of him who holds it, may sully its surface; whilst "the light and weightless down," if confided in, will delude more than the prince who is thus described as having been deceived by it, when carrying off the crown from the pillow of his royal father—

———"by his gates of breath

There lies a downy feather, which stirs not,
Did he suspire, that light and weightless
down

Perchance must move."

Another symptom, the opacity and want of lustre in the eye, is equally fallacious; even the thin alimy membrane which covers the cornea in the eye of the dead, which breaks in pieces when touched, and is easily removed from the cornea by wiping, sometimes is found many hours before death occurs; and I have seen it in cases which, after all hope had ceased, recovered. In several instances, also, this appearance does not present itself, even after death; as, for

instance, in cases of poisoning by hydrocyanic acid; in which the eye retains all its lustre for hours after death, and the iris even contracts when approached by a bright light. This sign, therefore, when taken alone, is of no value, although, in conjunction with others, it tends to confirm the suspicion that death has already gained his triumph. The state of collapse, which is one of the symptoms of the cholera asphyxia, now so disgracefully a bone of contention in the medical world, has demonstrated how little is the value of coldness of the body as a sign of death. In this singular disease, the coldness which accompanies the state of collapse is that of ice, and during it no pulsation can be perceived even at the heart, yet the person lives and breathes, and frequently recovers. Drowned persons, also, in whom animation is only suspended, and who may be recalled to life, are always cold; whereas in some diseases, apoplexy for example, a certain degree of warmth is perceived for many hours after death. I have noticed it in some bodies on the day after that on which the person died; and yet no doubt whatever existed that death had actually taken place. A beggar went to bed drunk, and died suddenly during the night. On the next evening he was carried to the anatomical hall in Padua, and on the *third* day after his death he was dissected. Morgagni, who operated, found the body still warm. Paleness and lividity of countenance always accompanies such a state of collapse as I have mentioned; the body even becomes blue; this sign, therefore, which is usually put down as one indicating death, is of less value than any of the others. Cases, on the other hand, have occurred in which the countenance has remained unchanged a considerable time after death; and, in some instances, as Dr. Paris has remarked, "its colour and complexion have not only been preserved, but even heightened," as if the spirit, scorning the blow which severed it from mortality, had left the smile it raised upon the moveless features—or, as Shakspeare would express it—

———"smiling, as some fly had tickled
slumber,

Not as death's dart, being laugh'd at."

Next to putrefaction, the rigidity of the limbs is one of the most certain signs of death. It is true, that stiffness of the limbs may proceed from several causes, but the rigidity thus produced is not difficult to distinguish from that of death. In some cases of syncope, and in catalepsy, there is considerable stiffness; but, in such cases, it is accompanied with warmth, and takes place, as Orfila has remarked, immediately after the commencement of the disease, whereas the stiffness of death does not commence until some time after death, when the animal heat is not longer perceptible to the senses.

The stiffness which occurs in some convulsive affections is, also, as readily distinguished from the rigidity of death, by the fact, that although there is great difficulty in changing the position of the rigid limbs, yet, when left, they immediately resume their former position; in the stiffness of death, the direction of the limb which has been changed does not return to its former position. Orfila has supposed that it is possible to mistake the stiffness of a person who has been frozen, but is not dead, with that which is the inevitable result of death; but, in the former case, the stiffness is uniform, the skin, mammae and belly, are as rigid as the muscles, a circumstance not present in the stiffness of death, in which the muscles alone display any degree of resistance. When the skin, also, of a frozen person is depressed by forcibly pressing the finger upon it, the hollow thus produced is a long time in disappearing. He adds, when the position of a frozen limb is changed, a little noise is heard, caused by the rupture of the particles of ice contained in the displaced part. It must, however, be remarked that this degree of freezing can only occur when the body has remained for some time after death exposed to extreme cold. I shall recur to this subject, in mentioning the signs which indicate that death has been the consequence of exposure to cold.

From all that has been said, it is evident that there are no certain signs that a person is truly dead, except the total cessation of respiration, and the commencing putridity of the body. The question then presents itself—By what means are we made aware of the existence of putrefaction? It is suspected in its earliest stage, when the body becomes soft, and begins to exhale an offensive odour, and the fleshy parts to assume a dark colour. When it is no longer doubtful, the odour is strongly ammoniacal, the parts seem as if dissolving, their colour is constantly altering, and they separate into a kind of gelatinous mass. In such states of the body there can be no doubt that death is actually present; but, if we wish to investigate its causes by dissection, no certain judgment can be formed on the state of the soft parts after the first stage of putrefaction, or rather a tendency to it has passed over. But dissection, even in the last stage, long after interment has taken place, if the object be to ascertain fractures or injuries to bones, and also in some cases of poisoning, where the substances are of a character not very susceptible of decomposition. Fodéré relates a case of a dead body having been found in a field, in the arrondissement of Trevoux, during the month of May, 1811. It was in a state of putridity, and the surgeon who was ordered to examine it, not liking the task, reported generally that he had discovered no marks of violence. But, on interring the body, it was remarked, on the dropping of a handkerchief which co-

vered the head, that the bones of the cranium separated, and the brain issued out. A special examination of the head was ordered, and it was found that this person had received three blows from a cutting instrument, which separated the parietal bones from the rest of the skull. The bones had been replaced, and secured with the handkerchief. The murderers were afterwards discovered and punished. No rules can be laid down as to the time after death which may be allowed to intervene, before putrefaction is likely to take place. If the person has died suddenly, it is likely to be retarded or accelerated only by the state of the weather; it is accelerated by heat and humidity, retarded by a cold and dry state of the atmosphere.

In the dissection of a body to ascertain the cause of sudden death, it is of importance to determine, as I shall have frequent occasion to notice, the distinction between violence done to the body during life and after death.

Hæmorrhage is usually supposed to indicate the existence of the circulation when the injury was inflicted, and, consequently, that the person was alive; but this is to be taken with some reservation. In those who die of malignant diseases, blood often flows from the mouth, nose, or ears; in which case, however, it is *thinner* and of a *black* colour than usual. Hæmorrhage, therefore, of itself is no proof that any wound had been inflicted during life, so as to destroy it; for when this really occurs, when death follows wounds capable of causing much hæmorrhage, the large vessels are generally found empty, and the blood is of a red or florid colour. Much care must also be taken not to confound ecchymosis and sugillations with contusions from violent blows. Ecchymosis is an effusion or spreading of blood into the cellular tissue, and may result from a violent blow rupturing one or more blood-vessels; but spots resembling ecchymosis appear soon after death, in debilitated habits especially, from the mere gravitation of the blood to the most depending part, or that on which the body rests. Zacchias says that these spots may be readily distinguished from ecchymosis arising from blows or bruises, from the blood in the part being fluid; whereas the discoloration or true ecchymosis from external violence, is characterized by a congestion of thick coagulated blood in the part.

Sugillations are, also, effusions of blood into the cellular tissue; but proceeding from internal causes such, for example as the commencement of the putrefactive process, such as sometimes occurs during life, for instance, in malignant and petechial fevers. But sugillation coming on after death is always confined to a dependent part, which is not necessarily the case when they are the result of blows or strangulation. The discoloured spots in dead bodies, if they arise

from blows, often bear the impression of the instrument with which the blow has been inflicted. In a trial which took place at the Lent Assizes, in 1765, at Kingston, in Surry, the prisoner, John Stringer, was condemned on the evidence of a young surgeon, that some marks on the corpse had somewhat of the appearance of mortification caused by bruises. Mr. Cassan, an eminent surgeon, who had previously examined the body, from mere curiosity, on hearing of Stringer's conviction, applied to the Archbishop of Canterbury, who obtained a respite from Baron Smyth, who tried the cause, and afterwards a pardon from the King, on the conviction that the marks on the body were not the consequence of blows or any injury.

Sudden death may be caused by ruptures of vessels in the brain, or the viscera of the thorax or abdomen; as in apoplexy and other diseases. It is of importance to distinguish these from effusions, the consequence of blows and wounds.

Having settled these general preliminaries, let us now examine the various causes of sudden death, and the manner of determining, from the inspection of the body, to which of these the death of a person found dead is to be attributed.

Syncope is that state in which the action of the heart and arteries cease, whilst there is yet some action of the respiratory organs. In ordinary fainting, some feeble action of the heart is still going on, although not sufficient to render any pulsation evident in the arteries, at much distance from the heart. If respiration have ceased, and the heart no longer pulsates, there is little probability that life can be restored; but the action of the heart may be arrested from many causes and be again roused to renewed action, if too long a period do not supervene before means are resorted to for effecting this. I once witnessed a very alarming case of syncope, which would in all probability have proved fatal if immediate aid had not been procured, or if any previous state of disease of the heart had been present. It arose from tight lacing. (The lecturer related the case).

In this instance, if this young lady had not left her dressing-room, and no assistance had been near, and she had died, nothing would have been more difficult than to have given any correct notion of the cause of death. In instances where, as I have said, the heart, or its vessels, has been previously labouring under some organic affection, the syncope induced by violent passions of the mind, or by sudden shocks, may terminate fatally from rupture of the heart. In the case of the celebrated John Hunter, who died from a fit of passion, the valves of the heart had long been in a state of disease. A case related by Dr. Valentine Mott, in the Transactions of the Physico-Medical Society of New York, is illustrative also of this fact. A ro-

bust, plethoric female of 22, addicted to intemperate habits, was deserted by the man to whom she was engaged to be married; in consequence of which, her mind became deeply affected. She supped on the preceding night, retired to rest as usual, and was found dead, next morning in bed. She lay in a bent incumbent position, as if in a profound sleep, with neither countenance nor limbs in the least distorted. On dissection a breach was found at the aortic ventricle, from which much effused blood which gorged the pericardium, had issued. The parietes of the ventricle around the ruptured part were much thicker than in the natural state, and on close examination a very sensible fluctuation was perceived, to the extent of an inch on one side of it, from which flocculi of a cheese-like substance were discharged on pressure; the pericardium, also, presented traces of inflammation. This disease would not, most probably, have terminated so suddenly, but for the affection of the mind.

A very interesting paper on a peculiar variety of asphyxia, which M. Chevalier, the author, termed *idiopathica*, contained in the first volume of the *Medico-Chirurg. Transactions* has much connection with this subject. It has even been contended by many able pathologists that it may happen in a sound state of the organ. A most excellent illustration of this is given by Dr. Fischer.

See translation from *Journal Pratischen Heilkunde*, Dec. 1817, in the *Medical Repository*, vol. xi, p. 422.

In dissection, therefore, of cases of sudden death, from rupture of the heart, it is of the first importance to ascertain the previous state of the organ; and this is of the utmost moment in many questions connected with life insurance; for in the event of previous disease being detected in the aorta, an objection may be raised by the office on the score of a false certificate of warranty of health; for it cannot be denied that such a state of the heart or large vessels tends greatly to shorten life; and it is only upon the truth of the warranty that the validity of the contract depends. Again, it is of equal importance in cases of supposed homicide. Thus two men quarrel, and during the scuffle the one hits the other a blow on the chest, after which, he immediately falls down and dies. On dissection the heart is found ruptured. It becomes then an important question—in what state was the organ previously to the quarrel taking place; because, if it were in such a state that any strong mental emotion would endanger life, the condemnation of the accused person would be an act of flagrant injustice; but, in what manner can this be determined unless by careful dissection? What are we to look for? The reply is, disease either in the substance of the heart, or in the coats of the large arterial trunks, or in the valves.

A person, in a fit of passion, is pushed down, and dies suddenly; on opening the body, no blood is found effused in the pericardium, but there is an unusual enlargement and thickening in the muscular substance of the heart; and much blood is found effused in the brain. This might, erroneously, be ascribed to the fall; whereas it is more likely to have arisen from the impetus impressed on the blood by such a state of the heart, during the excitement of anger, being greater than the resistance of the vessels of the brain can sustain. In such a case, the arterial system may be said to be overloaded on every occasional excitement affecting the heart; the venous system cannot return the blood in an equal ratio, thence the arteries become gradually weakened, and at length, on a sudden excitement some one or other of them gives way. In such a case, the person who caused the fall, which preceded death, must be held guiltless. Instances of sudden death have occurred from no other obvious cause than the heart being overloaded with fat. Bonnet ascribes the sudden death of a very fat man to this cause; it causes suffocation. Thence this state of the heart must not be overlooked.

The sero-fibrous parts of the heart may be ossified by earthy matter deposited in the fibrous tissue, a fact which can be known only by removing the internal membrane of the organ; or the earthy matter may be

deposited in a kind of irregular crystallizations, forming unequal surfaces, covered also by the internal membrane of the heart. Indurations and ossifications of the whitish bands surrounding the ventriculo-auricular apertures, are also to be sought for, as well as cartilaginous and ossified states of both the mitral and semilunar valves, preventing the due transmission of blood from the cavities, and thence favouring rupture on its sudden accumulation in them, as is often the case in the early stage of these changes in the valves, when paroxysms of passion are instantly fatal.

Sudden death may also take place in aneurisms of the aorta, either from internal hæmorrhage, from bursting of the aneurismal sac; or from apoplexy, owing to compression of the aneurismal tumour, diminishing the area of the vena cava superior, when the aorta, in the superior part of the chest, is the seat of the disease.

Scarcely any age, except infancy, and no sex, is exempt from these affections of the heart; and the evil progresses, too often, in so imperceptible a manner, that it is not known until the fatal event display itself. When this involves a medico-legal inquiry, nothing is more justly disgraceful to a medical man than ignorance as to the nature of the appearances which dissection is calculated to display, and a consequent erroneous decision respecting the real cause of death.

LECTURES

ON THE

INSTITUTIONS OF MEDICINE,

DELIVERED BY JOHN FLETCHER, M.D., F.R.C.S.E., AT THE ARGYLE SQUARE SCHOOL OF MEDICINE, EDINBURGH; SESSION 1834-35.

LECTURE XVIII.

Evidences that the Ganglionic System of Nerves is the Seat of Irritability—(continued).

IN the last lecture it has been stated that it was very usual to describe the nervous cords that pass between the cerebro-spinal system of nerves and the ganglions of the great sympathetic as the roots or origins of the latter, and those only which pass between the ganglions and other organs as their branches. Reasons were advanced to shew that, even admitting this description of the origin of the ganglions to be true, no objection to the doctrine which ascribes the sources of irritability to them, could be maintained. But what right have we, except the gratuitous assumption that the cerebro-spinal system is the only source of nervous influence, to presume that the nervous cords which extend between this system and the ganglions are always branches from the former to the latter; nay, have we not a greater right—considering the priority of development of the latter system—to presume directly the reverse, and to consider them rather as branches from the ganglionic system to the cerebro-spinal? Thus are we equally, if not more justified *à priori* in regarding the twigs which extend between the motor oculi and the ophthalmic branch of the trigeminus, on the one hand—the reputed origins of the ophthalmic ganglions—and this ganglion, on the other, as proceeding from the latter to the two former, as in the opposite direction

those extending between the upper maxillary branch of the trigeminus and the abductor nerve, on the one hand—the alleged origin, in like manner, of the great sympathetic nerve—and the cavernous ganglion, on the other, as branches from this ganglion to the cerebro-spinal nerves in question as the reverse; and those lastly which extend between the several cervical, dorsal, lumbar, and sacral nerves—the so-called origins of the spinal ganglions—and the corresponding ganglions, as offsets backwards from the ganglions as forwards from the spinal nerves? Nor are there wanting many and strong arguments *à posteriori* in favour of the former opinion. The twig, for example, extending between the abductor nerve and the cavernous ganglion—to say nothing of the retrograde angle, at which, if we presume that it proceeds from the former to the latter, it is sent off (*a*)—partakes much more of the physical characters of a ganglionic than of a motiferous nerve, being much softer and less uniformly white and opaque than the abductor (*b*), and quite destitute of the fibrous structure, and proper tubular neurilema which characterize all the motiferous nerves (*c*): further, the abductor nerve is not smaller and weaker beyond the point where this union takes place, but larger and stronger (*d*), appearing clearly to indicate that it has gained a filament instead of losing one. Comparative anatomy moreover is decidedly hostile to the common opinion respecting the origin of the great sympathetic nerve from the abductor; since, in the majority of the lower animals, the filaments extending from the upper cervical ganglion into the carotid canal have no connexion with this nerve whatever (*e*). And similar remarks may be made with respect to the twigs which extend between the several spinal nerves and the corresponding ganglions of the great sympathetic—that they approach much more nearly in their physical characters to ganglionic than to cerebro-spinal nerves, and that there is frequently no manner of correspondence between the size of the respective ganglions and the size or number of these twigs from which they are so confidently described as arising; nor can it be said that this may depend upon the reinforcements which the ganglions receive from above and from below, from the trunk of the great sympathetic, itself derived from the cerebro-spinal system, when it is considered, first, that this origin of the great sympathetic is one of the chief points at issue, and secondly, that the want of proportion in the size of the ganglions is as remarkable when compared with their perpendicular, as with their lateral filaments—nay, that the great sympathetic nerve is not unfrequently entirely discontinuous without making any considerable difference in this respect (*f*). Now, if it be conceded that these and other filaments extending between the cerebro-spinal and ganglionic systems and nerves are branches from the latter to the former, or even that, wherever such a union takes place, there is a mutual interchange of filaments—which is perhaps the most rational opinion (*g*)—it will follow that to whatever organ of the body any cerebro-spinal nerve proceeds, there a ganglionic filament may be presumed to accompany it; since there is no such nerve, to whatever department of the cerebro-spinal system it may belong—with the exception of the three nerves of specific sensibility, the olfactory, optic and auditory, which proceed each to organs already abundantly supplied with nerves from other sources—with which the ganglionic system is more or less directly connected (*h*). Thus, of the respiratory nerves, the pathetic is connected with the ophthalmic ganglion; the facial with the sphenopalatine and sub-maxillary; the glosso-pharyngeal with the upper cervical; the pneumogastric with all the ganglions of the spine, as well as with the cardiac and coeliac; and the accessory, phrenic, and external respiratory again with the cervical. Of the motiferous

(*a*) Winslow.

(*c*) Soemmering.

(*d*) Petit, Soemmering, &c.

(*e*) Swan, on the Nerves, 1835. "No doubt," says Mr. Swan, "can be maintained that the branches proceed from the sympathetic to the sixth."

(*f*) Haller, Bichât, &c.

(*g*) In these instances "we have reason to believe," says Dr. Wilson Philip, "a double communication takes place, the spinal nerves conveying to the sympathetic the influence of the spinal marrow, and the sympathetic with them, to the parts to which they are distributed, filaments conveying the influence of the ganglionic system."

(On the Vital Functions, 1826). How inconsistent is this—in all probability the true statement of the case—with the principle, only two pages before inculcated, that "we cannot hesitate to regard the sympathetic nerve as arising from the spinal marrow!" If all the properties or powers which this nerve possesses be derived from the source in question, what "influence" can it possibly communicate to the spinal cord, which that organ had not before?

(*h*) The nerves of the human body may be conveniently classified under the two great heads of ganglionic and cerebro-spinal, the latter being subsequently distributed into the four sub-divisions of respiratory, motiferous, sensiferous, and regular, the last

nerves, the motor oculi is connected with the ophthalmic ganglion; the motiferous filament of the lower maxillary branch of the trigeminus with the sub-maxillary; the abductor with the cavernous, and the hypo-glossal with the upper cervical. Of the nerves of general sensibility, the ophthalmic branch of the trigeminus is connected with the ophthalmic ganglion; the upper maxillary branch of the trigeminus with the spheno-palatine and cavernous ganglions; and the sensiferous filament of the lower maxillary branch of the trigeminus again with the sub-maxillary—to say nothing of the connection which each of these branches may be presumed to have with the upper cervical ganglion, filaments of which are copiously distributed upon the gasserian ganglion through which they pass. Lastly, of the regular nerves, the sub-occipital is connected with the upper cervical ganglion; and all the cervical, dorsal, lumbar, and sacral nerves, not only directly with all the corresponding ganglions throughout the whole course of the spine, but also indirectly with the cardiac and coeliac ganglions. We seem to be fully warranted therefore in concluding, not only that wherever is a blood-vessel, there are ganglionic nerves as a part of that blood-vessel, but also that wherever is a nerve, to whatever department of the cerebro-spinal system it may belong, there some filaments from the ganglionic accompany it; and consequently that, so far from this system being confined to the several viscera, it is so universally distributed over the body, as to be abundantly competent, as far as this condition is concerned, to impart irritability to every muscle, whether ministering to the organic or animal functions.

11.—With respect to the continuance in action of the ganglionic system of nerves under circumstances in which that of the cerebro-spinal system is suspended or lost, the fact that it does so has been acknowledged even by those who are the strongest advocates for its dependence upon the cerebro-spinal system; and it was to reconcile this fact with their general hypothesis, that they invented the doctrine that the ganglions served as receptacles of animal spirits, which were derived primarily from the brain, but which might be so doled out by the ganglions, as to carry on the organic functions for some time without the agency of the former. But why, it may be asked, should the animal spirits, as doled out by the ganglions to the several viscera, differ so materially in their character from the same spirits as proceeding directly from the brain; and why should they, as conveyed to a limb

including those which communicate both the faculty of sensibility and the stimulus of volition. Adopting this general arrange-

ment, the following are the individual nerves "after their kind":—

GANGLIONIC.

CEREBRO-SPINAL.

Those immediately connected respectively with the *Ophthalmic*, the *Cavernous*, the *Otic*, the *Spheno-palatine*, the *Sub-maxillary*, the three *Cervical*, the *Cardiac*, the twelve *Dorsal*, the *Coeliac*, the five *Lumbar*, the five *Sacral*, and the *Coccygeal* ganglions.

<i>Respiratory.</i>	<i>Motiferous.</i>	<i>Sensiferous.</i>	<i>Regular.</i>
The Pathetic, The Facial, The Glosso-pharyngeal, The Pneumogastric, The Accessory, The Phrenic, The External Respiratory.	The Motor Oculi, A part of the lower maxillary branch of the Trigeminus, The Abductor, The Hypo-glossal.	The Olfactory, The Optic, The Ophthalmic branch of the Trigeminus, The upper maxillary branch of the Trigeminus, A part of the lower maxillary branch of the Trigeminus, The Auditory.	The Sub-occipital, The seven Cervical, The twelve Dorsal, The five Lumbar, The five Sacral.

Of these ganglions the cervical, dorsal, lumbar, and sacral were known to Galen. The coeliac was discovered by Willis, in 1664, the spheno-palatine and sub-maxillary by Meckel, in 1719, the ophthalmic by Zinn, in 1755, and the cardiac by Wurberg, in 1780; and comparatively recently the cavernous by Bock or Lermontier, and the otic by Arnold. The naso-palatine ganglion, the reputed discovery of Cloquet, has been omitted, as its existence is somewhat questionable; and the gasserian ganglion belongs to the cerebro-spinal, and not to

the proper ganglionic system. With respect to the cerebro-spinal nerves and their arrangement, it is proper to observe that there is hardly one of those above enumerated, the origin and functions of which have not been more or less questioned; and perhaps few or none of them, owing to the frequent union of most, if not all of them, with nerves of other systems, are exclusively what they are represented to be in the foregoing schedule. The present however is not the place for discussing their pretensions to the positions which they severally occupy.

by the ganglionic nerves, minister only to nutrition, secretion, and absorption, whereas, as conveyed to the same limb by the cerebro-spinal nerves, they minister to sensation and voluntary motion? It is an obvious inference from the fact that all those functions, whether of the viscera, or of the rest of the body, which require only irritability for their exercise continue unimpaired during sleep, in comatose diseases, and even for some time after apparent death, and from the acknowledgment that the ganglionic system continues in action under these circumstances, that this system is, not a mere reservoir of properties and powers which it never imparts, but a primary source of a property which, during the suspended action of the brain, is alone in requisition; and it is a strong corroboration, as already remarked, of the principle which would trace ganglionic nerves to every point of the body, that, so long as the functions of organs which minister exclusively to the organic functions, and which are supplied almost exclusively from this system, continue to be performed, many of the functions even of organs which minister more particularly to the animal functions, and which are supplied more remarkably from the cerebro-spinal system, remain unimpaired.

III.—It is a distinguishing feature in the character of the ganglionic system of nerves, that its filaments are every where small, and in many parts so minute as to be altogether invisible; and hence not only was the system in general comparatively very late in being discovered, and much later in being generally admitted by physiologists, but the existence of some parts of it has been, in recent times, denied, as already stated, even in organs in which the filaments are much less obscure than in many others (*a*). It is easy to conceive then that certain stimuli, by which muscles have been excited to contraction, may have been really applied to such filaments, when, to all appearance, they were applied directly to the muscular fibres; and thus that the latter may have appeared to possess inherently a quality which in fact they derived from the former.

IV.—If filaments from the ganglionic system of nerves everywhere accompany the blood-vessels, as well as, in all probability, are associated with all the cerebro-spinal nerves, it is evident that cutting the latter in their course to any organ, or even removing the brain, needs not materially interfere with the irritability of this organ, since a sufficient supply may still be furnished from the former source. But it is probable that no impediment whatever is offered to the function of a ganglionic nerve by such a division as entirely paralyses the cerebro-spinal. Such is the case with the latter only because the white matter of the nerve being dependent for its energy upon the grey matter of the central parts of this system, becomes of course inert when separated from it; but no such line of demarcation exists in the ganglionic system, every point of every nerve of which contains white and grey matter intimately interwoven together, and may be considered therefore as a centre of nervous energy to itself (*b*), and it is in this way only that it can be explained that the total removal of a muscle from the rest of the body, which implies a division, as well of its blood-vessels as of its nerves, is not, for some time, effectual in destroying its irritability. It has indeed long been known that dividing the large blood-vessels going to a muscular part has, after an interval, a much greater effect in impairing its contractility, than dividing its principal nerves (*c*), a fact which has been supposed to show—as will be in future insisted upon at greater length—that, while the capability of obeying a stimulus is inherent in the muscular fibre, it is by a certain influx of blood into it that its contraction is immediately effected; but it is not perhaps either from preventing this supposed influx, or from intercepting the influence of the ganglionic nerves which accompany these blood-vessels, that this effect results, but from, sooner or later, impeding the functions of the parenchyma of the part, the office of which is to renew ganglionic nervous matter, as well as every other tissue, in proportion as it is consumed. At all events, no conclusion prejudicial to the doctrine that the ganglionic nervous system is the immediate seat of irritability, can be fairly drawn from the results of any experiments of this nature.

V.—Again, that this system of nerves would be competent to renew the property of irritability in a part, the principal nerves of which had been divided, and so much of its immediate stock of irritability afterwards suddenly exhausted as to disqualify the larger muscles for any further contraction, might almost be inferred from the contents of the preceding paragraph. If irritability be the attribute of the tissue in question, it can be destroyed only in proportion to the destruction of this tissue; and were this destruction entire, it is obvious that any renewal of it must be impossible, since the failure would extend, not only to the larger muscular fibres, but to the parenchyma also, on the actions of which is one only reliance for the renewal of the ganglionic nervous matter, and with it— independent, as it is, of any common centre—of its characteristic property. But we must remember that in all cases of a general failure of irritability from natural causes, that of the capillary vessels long survives that of the larger muscles; and if the same thing hap-

(*a*) Soemmering and Behrend.

(*b*) Bichat.

(*c*) Stenon, Cowper, Boerhaave, &c.

pen when it is withdrawn artificially, it is easy to understand how a degree of exhaustion of it which shall entirely incapacitate, for a time, the larger muscles for any further contraction, should be quite compatible with a subsequent restoration of these organs to their natural susceptibility.

VI.—With respect to the earlier appearance, as we rise in the scale of animals, of the ganglionic than of the cerebro-spinal system of nerves, this argument, in favour of regarding the former as the immediate seat of irritability, is probably well founded, if it signify merely that we are to look upon the minute nervous nodules which first display themselves in animals forming, as it were, a connecting link between those which present no traces whatever of nervous matter, and those which have a regular nervous apparatus, as appertaining rather to the ganglionic than to the cerebro-spinal system of the superior tribes; but not if it compel us to regard—as some physiologists have done—the more or less concentrated nervous systems of all the invertebrate animals as corresponding merely to the ganglionic system of the vertebrate (a). Wherever a distinct nervous apparatus exists at all, whether in an invertebrate or vertebrate animal, that apparatus seems to correspond to both a ganglionic and cerebro-spinal, and not exclusively to either; and the only difference between such an apparatus as found in the invertebrate, and as found in the vertebrate animals, appears to be that the main portions of the two systems of which it consists are not, in the former, separated from each other by a distinct spinal column and skull, but directly amalgamated together, whereas, in the latter, they are so separated, and are connected with each other by reciprocal filaments interposed at certain intervals. The only means—short of any positive evidence of its correspondence with one or other of these systems—of determining the character of the apparently simple nervous apparatus of the invertebrate animals appears to be by observing, 1st, the general aspect and relative size of this apparatus; 2ndly, the situation of its principal departments; 3dly, the func-

(a) So long as the cerebro-spinal system of nerves was alone generally recognised in the higher tribes of animals, it would of course follow that such nerves as could be detected in the lower tribes, were considered to appertain to this, and such was at first the almost universal impression with respect to the nature of the nervous apparatus of the invertebrate animals in general; nor did the general recognition of the ganglionic system of nerves for some time make any difference in this respect, since they were for a long time regarded as merely an appendage to the cerebro-spinal. The subsequent establishment, however, of the independence of the former, coupled with the observation that the functions to which it seemed to be subservient in the higher tribes of animals were of more essential importance to their life and well-being than those to which the cerebro-spinal system was appropriated, soon led to the conclusion that in the invertebrate animals, which appeared to have only one of these systems, it was analogous, not to the cerebro-spinal, as had been supposed, but to the ganglionic system of the vertebrate. This was the opinion of Reil, and having been embraced by Bichat, it soon became, like most of the doctrines which he advocated, to a certain degree popular, and has been explicitly supported by Ackermann, Virey, Parker of Birmingham, and many others. Virey, indeed, has ventured to arrange animals, with reference to their nervous apparatus, into three classes, the first consisting of those which manifest nothing but nervous granules, more or less isolated, including only some of the lowest tribes of invertebrate animals; the second those which possess a distinct ganglionic, but no cerebro-spinal system, including all the

rest of the invertebrate tribes; and the last those which possess both, including all the vertebrate animals. It is probable, however, that—whatever we may think of the nervous granules here spoken of as corresponding exclusively to the ganglionic system—there is no instance of a *distinct* nervous apparatus at all which does not include both the ganglionic and cerebro-spinal systems, and consequently that Virey's supposed second class of animals has no existence. It is strange that the advocates of the doctrine which ascribes only a ganglionic system of nerves to any of the invertebrate animals should have neglected to notice that many of them manifest the most unequivocal marks of sensation and voluntary motion; so that it would have been equally reasonable to conclude *a priori* that their supposed simple system was cerebro-spinal as that it was ganglionic—nay, it would have been even more reasonable to come to this conclusion, since most of the other functions which they perform they exercise only in common with plants and quite the lowest tribes of animals, which have no obvious nervous system at all, whereas in sensation and voluntary motion they approach the highest tribes of the latter, which are never destitute of such a system. It was from taking this view of the matter that the old opinion has been, in recent times, maintained by Blumenbach, Cuvier, Gall, Rudolphi, Bell, and others, who look upon the apparently simple nervous apparatus of the invertebrate animals as corresponding, not so much to the ganglionic as to the cerebro-spinal system of the superior tribes—true to the maxim that “*in vitium ducit culpæ frega*,” as having failed to perceive that it corresponds equally to both.

tions of the organs on which it is distributed; and lastly the effects of direct experiment upon it. With respect, then, to its general aspect, the usually knotted and disjointed appearance of the nervous system of the invertebrate animals seems, at first sight, to favour the opinion that it corresponds exclusively to the ganglionic system of the vertebrate; but it must be remembered that, although, in the higher tribes of the latter, the ganglionic system has this appearance, while the cerebro-spinal is more or less cylindrical and continuous, the reverse is the case in the lower, such as fishes, in which, with very few exceptions, the sympathetic system is without knots and filaments, while the spinal cord and brain have often a somewhat knotted and unconnected appearance, and it is only as we rise through reptiles and the other intervening tribes that the two systems of nerves acquire gradually the appearance by which they are at length characterised. Now it is with fishes, as the next in rank to themselves, that the invertebrate animals should be compared in this respect; and the comparison necessarily leads to the conclusion that the bulk of their nervous apparatus is analogous to the cerebro-spinal system of the former, some minute filaments only corresponding to the sympathetic—the more especially, as the transition from the large nervous apparatus of many of the invertebrate tribes to the ample spinal cord and brain of fishes is progressive and easy, while to the slender sympathetic system it is retrograde and violent. We know, moreover, that in the metamorphoses of many insects, as the Moth (*a*), (*Sphinx*, 20), and the Hornet-Fly (*b*), (*Asilus*, 23), from the state of larva to that of pupa, and from the state of pupa again to that of imago, several of their large nervous knots coalesce into a kind of knotted cords, making a very near approach, both in appearance and in relative size, to the spinal cord and brain of the lower vertebrate tribes, but altogether dissimilar, in both these respects, to their sympathetic system. The situation, again, of the principal departments of the nervous apparatus of the invertebrate animals—as far as this is of any importance—is favourable to the opinion that it corresponds at least as much to a cerebro-spinal as to a ganglionic system. The first rudiments of a nervous system visible in these animals, and the part of it which is most constantly met with, is a knot on the dorsal aspect of the part corresponding to a neck, sending a kind of collar round the gullet; and it is from some part of this that a chain of knots in general proceeds along the body. Now, this rudimental part of the nervous system, is in some invertebrate animals, as the Cuttle (*Sepia*, 10), contained in a kind of rudimental skull, and may be therefore fairly presumed to correspond to a brain; while the chain of knots along the body, contained, as it is in some, as the Cray-Fish (*c*) (*Cancer*, 16), in a partial horny canal formed by the shell, and in others, as some species of Grass-hopper (*Gryllus*, 25), in a similar canal formed by the segments of their sheath, may be with equal reason presumed to be analogous to a spinal cord, the latter indeed has, distinct from the main chain of knots in question, two smaller cords which seem to correspond with a sympathetic system. It is true this main chain of knots, in many invertebrate animals, as the Leech (*d*) (*Hirudo*, 13), the Earth-Worm (*e*) (*Lumbricus*, 13), the Sea-Mouse (*f*) (*Aphrodita*, 14), the Cray-Fish (*g*) (*Cancer*, 16), and insects in general, runs along their abdominal rather than along their dorsal aspect, but in others on the contrary, as the membranous Ascidia (*h*) (*Ascidia*, 6), the Mussel (*i*) (*Mya*, 7), the Sea-Hare (*k*) (*Aplysia*, 8), and the Garden Snail (*l*) (*Helix*, 9), it holds its course along their back, so that no weight can be assigned to this circumstance in regarding it as corresponding rather to the ganglionic, than to the cerebro-spinal system. In some insects indeed, as the Grass-hopper (*Gryllus*, 25), just mentioned, while the portion of the nervous system which corresponds to a spinal cord, runs along their abdominal, that corresponding to a sympathetic system runs along their dorsal aspect; but we know that the situation of parts is in general a consideration of very little importance in tracing structural analogies. If we attend also, to the functions of the organs on which the chief nerves of the invertebrate tribes are distributed we shall not hesitate to believe that they are analogous, at least equally, to the cerebro-spinal system as to the ganglionic. The nervous collar just alluded to, as the first visible trace in animals of a distinct nervous system, ministers directly to the motion of the jaws, or corresponding organ, and to taste, and thus corresponds distinctly to the lower maxillary branch of the trigeminus nerve—in its motiferous and sensiferous filaments—of the higher classes of animals; round the pharynx and gullet of which in fact, a similar collar is formed by the nerve in question, although, from the comparative complexity of the parts, it is less immediately obvious. The first visible nerve then is a branch of the cerebro-spinal system. It is certain likewise that most invertebrate animals send nerves directly to other organs

of voluntary motion and sensation besides the jaws and tongue—the Star-Fish (*a*) (*Asterias*, 5), for example, to the tentacula, the Garden-Snail (*b*) (*Helix*, 9), to the muscles of the neck and of locomotion, as well as to the eyes and feelers, the Cuttle (*c*) (*Sepia*, 10), to the tentacula, eyes and ears, the Sea-Mouse (*d*) (*Aphrodita*, 14), to the tentacula, the Cray-Fish (*e*) (*Cancer*, 16), to the antennæ, legs and tail, the nostrils, eyes and ears, the Silk Worm (*f*) (*Phalæna*, 20), to the muscles of the head, the feet, wings, and eyes, the Bee (*g*) (*Apis*, 23), to the feet, wings and eyes, and so forth; and such nerves must accordingly be presumed to correspond, not to the ganglionic, but to the cerebro-spinal system of the superior tribes. On the other hand it must not be forgotten that it is not only to the organs of voluntary motion and of sensation, that nerves proceed from the apparently simple nervous apparatus of the invertebrate animals, but also to those of respiration, circulation, digestion and generation, as is sufficiently manifest among those just mentioned in the Garden-Snail (*Helix*, 9), the Cuttle (*Sepia*, 10), the Cray-Fish, (*Cancer* 16), the Silk-Worm (*Phalæna*, 20), the Bee (*Apis*, 23), and numerous others; and such nerves we are compelled to believe correspond, not to the cerebro-spinal system, but to the ganglionic. Lastly it has been found that the removal of the central parts of the nervous apparatus of the invertebrate animals is attended with fatal consequences (*h*); which in all probability would not have happened, had it corresponded exclusively to the ganglionic system, and not also to the cerebro-spinal. This assertion appears, at first sight, somewhat opposed to the presumption, hitherto constantly insisted on, that the former furnishes a property much more immediately essential to life than the latter; but it must be kept in mind that every point of the ganglionic system being a centre of nervous influence to itself, the system collectively is quite independent on any common centres, and accordingly, not only may all communication with such common centres be cut off—as has been already stated—but the latter may be altogether withdrawn—as will be stated more fully in future—without destroying, or even sensibly impairing the function of the nerves connected with them. Such is not the case, however, with the cerebro-spinal system; which, although it ministers to functions less immediately essential to life than those to which the ganglionic system is subservient, cannot be supposed to be thus violently destroyed, without, sooner or later involving the system in general in its destruction.

A NEW PRACTICAL FORMULARY

OF HOSPITALS, OR A

Collection of Formulæ of the Civil and Military Hospitals of France, Germany, Italy, Great Britain and Ireland, &c., containing the Indication of the Doses in which simple Substances, magistral and officinal Preparations of the Codex are administered, the use of New Medicines, and general receipts on the art of prescribing. By M. EDWARDS, M. D., and P. VAVASSEUR, M. D., of the Hospitals of Paris—1834. Translated and augmented by M. RYAN, M. D. &c. &c.

(Continued from p. 371.)

Narcotic Decoction. M. de Santé.

Rx. Papaveris capsularum. No. ij;
Florum sic. belladonnæ, ʒj;
Aquæ, Oj.

Coque et cola.

Employed in local baths, fomentations, injections, &c.

An Emollient and Anodyne Injection.

Rx. Decocti papaveris, Oj;
Emulsionis arabicæ, ʒv;
Albuminis ovi, ʒj.

Fiat injectio.

Employed in acute urethritis.

Anodyne Enema. H. de la Mat.

Rx. Papaveris capsul. No. j;
Decocti lini, Oij.

Decoque et cola.

Anodyne Enema. H. St. Ant.

Rx. Papaveris capsular. ʒss;
Aquæ, Oj.

Coque tum cola.

The Enema of Poppies of the H. des Enf. contains only ʒij of poppies to the same quantity of water.

Antidiarrhæal Enema.

Rx. Syrupi papaveris, ʒij—iv;
Decocti amyli, ʒviij.

Fiat enema.

Employed in colliquitive diarrhæa, and in purging of infants.

[Sedative enemata are efficient in dysentery, hæmorrhoids, abdominal inflammation, &c. The starch and opium enema is an old and valuable remedy. The dose of the latter is ʒss—j. T.]

RED POPPIES.

Emollient and slightly narcotic. Employed in pulmonary catarrh, and other inflammatory affections &c.

INTERNALLY. Decoction, or infusion. Pinc., ij—iv to Oij of water.

Eau de Cuquelicots. P. ʒj—iv, as a vehicle for antispasmodic and sedative potions.

Sirop de Coquelicots. P. 3 iv—3 j, in a potion.

Infusion of Red Poppies. H. de la Ch.

Rx. *Florum rhœados*, 3 ij;

Aquæ ferventis, Oij.

Macera et cola.

The dose is a small cupful while hot.

Pectoral Infusion. H. de Lyon.

Rx. *Florum rhœados*, 3 ij;

Acidi sulphurici diluti, gut. xv;

Sacchari, 3 j.

Macera omnia in.

Decocti hordei, Oj.

Cola, sumat in die.

ACETATE OF MORPHIA.

A very energetic narcotic, possessing the same properties as opium. It is employed in the same cases as that medicine.

INTERNALLY. Gr. $\frac{1}{2}$ —ij in the twenty-four hours, in pills, or in a potion.

Solution of the Acetate of Morphia. F. de M. (*Acetate of morphia*, gr. xvj; distilled water, 3 j; acetic acid, gut. iv; alcohol, 3 j). Gut. vi—xxiv, in a potion. 3 ss of this solution contains about gr. 1 of the acetate of morphia.

Sirop of Morphia. F. de M. (*Acetate of morphia*, gr. iv; common syrup, ℥ij). Cochl. min. j, every two or three hours, or 3 j in a potion. 3 j contains $\frac{1}{4}$ of a grain of the acetate. This syrup replaces with advantage the syrup of poppies.

Sedative Potion. H. of Italy.

Rx. *Solutionis morphine acetatis*, gut. xx;

Extracti lactuce virosæ, gr. x;

Syrupi althææ, 3 j;

Infusi anthemidis, 3 v.

Misce.

Dosis cochl. mag.

Sedative Emulsion. H. of Italy.

Rx. *Syrupi morphine acetatis*, 3 j;

Mucilaginis acaciæ, 3 viij.

Dosis cochl. mag.

Sedative Pills.

Rx. *Morphine acetatis*, gr. j;

Confectionis aurantii, gr. xvj.

Divide in pilulas viij, sumat unam vel duas sextâ quaque horâ.

In neuralgia, cancerous affections, &c.

Boluses used in Catarrh. H. de Mont.

Rx. *Morphine acetatis*, gr. ij;

Extracti hyoscyami albi, gr. vj;

Balsami sulphuris,

Extract glycyrrhizæ, ā ā gr. xvij;

Croci,

Gummi tragacanthæ, ā ā 3 jss;

Butyri cacao, 3 j.

Fiant boli xxxv ex quibus capiat unum secundâ vel tertiâ quaque horâ.

In cases of catarrh accompanied with great irritation.

Each bolus contains gr. 1-18th of the acetate, and gr. 1-6th of hyoscyamus.

EXTERNALLY. Gr. $\frac{1}{4}$ to j. applied to a blistered surface, according to the endermic method, in the same cases as it is employed internally when it is feared it would cause too much irritation of the stomach.

[It may be mixed with lard or simple cerate, in liniments and ointments. T.]

SULPHATE OF MORPHIA.

Its action is the same as that of the acetate, [and it is administered in like doses, sulphuric being substituted for acetic acid. T.]

INTERNALLY. Gr. $\frac{1}{4}$ —j, in pills.

Syrup of the Sulphate of Morphia. F. de M. (*Sulphate of morphia*, gr. iv; common syrup, ℥ij). Cochl. min. j, every hour or every three hours, or 3 ss—j in a potion. 3 j contains gr. $\frac{1}{4}$ of the sulphate.

Sedative Pills. H. of Italy.

Rx. *Sulphatis morphine*, gr. j;

Olei olivæ, q. s.

Liqua sulphatem et adjice.

Ipecacuanhæ, gr. iij;

Nucis vomicæ, gr. ij;

Miccæ panis,

Mellis, ā ā q. s.

Divide in pilulas vi, ex quibus sumat unam tertiâ quaque horâ.

CITRATE OF MORPHIA.

It acts in the same manner as the other salts of morphia, and is used in the same cases.

[It irritates the stomach less than the other preparations, and is the most active according to some writers. It is not much used in this country. T.]

INTERNALLY.

Solution of the Citrate of Morphia. F. de M. (*Morphia pure*, gr. xvj; crystallized citric acid, gr. viij; distilled water, 3 j; tincture of cochineal, 3 ij). Gut. vj—xx in the 24 hours, in a potion.

HYDROCHLORATE OF MORPHIA.

This preparation of morphia enjoys the same properties as the preceding. It is preferred as an hypnotic.

INTERNALLY.

Solution of the Hydrochlorate of Morphia. H. of England.

Rx. *Hydrochloratis morphine*, gr. x;

Aquæ destillatæ, 3 xiv.

Liqua.

The dose is gut. xv—xxv, in a potion, or in a little water sweetened with sugar. (100 drops contain gr. 1 of the hydrochlorate or muriate of morphia).

[This preparation is recently preferred by British physicians. T.]

NARCEINE—MECONINE—CODEINE.

Three substances have been recently discovered in opium—*narceine*, *meconine*, and *codeine*.

Narceine was discovered in 1832, by M. Pelletier; and *meconine* the same year by M. Couerbe. Both are obtained by evaporating the ammoniacal solution in which morphine is precipitated to the consistence of syrup during some weeks, when a crystallous mass is deposited. This is submitted to pressure, heated with boiling alcohol, 40° Rem.; the alcohol is distilled, when a yel.

low crystallised residue is obtained, which is redissolved in alcohol and filtered through animal carbon. The mass which remains is composed of narceine and meconine; it is heated with boiling water to separate a small portion of narcotine which it sometimes contains; and then ether is added to dissolve the meconine without affecting the narceine. These substances have not as yet been used medicinally.

Codeine was discovered in 1832, by M. Roubiquet. He obtained it by decomposing the double muriate of morphine and codeine, which is the hydrochlorate of morphine of Gregory, of Edinburgh, by ammonia, which precipitates the greatest portion of the morphine. The solution is evaporated until signs of crystallization appear, the liquor is left at rest, and the double salt of morphine and codeine is crystallized. This is dissolved in water, and strained through animal charcoal; a solution of caustic potash is added in slight excess, which holds the morphine in solution and precipitates the codeine alone, and this is purified by alcohol or ether.

M. Barbier states that codeine has a remarkable effect, a special action on the ganglionic nerves, especially in the epigastric region. (*Gazette Medicale*, April, 1834).

M. Magendie has administered it to several of his patients at the Hotel Dieu, in the dose of half a grain, increased to a grain; it produced a tranquil sleep, which was not followed next day by somnolence or heaviness in the head, a frequent consequence of morphine; one grain is equal to half a grain of morphine. He gives one, two, or three grains in a mucilaginous emulsion, and also in pills—one grain in each. He has used the hydrochlorate of codeine in facial and sciatic neuralgia, which resisted all other means, with an effect as if caused by enchantment. He has also used the nitrate of codeine. The salts of this substance are more energetic than their base, and should be used in smaller doses. Many diseases which withstood the preparations of morphia have yielded to this.

The double muriate of morphine and codeine of Gregory may be used in the same doses and diseases as the preparations of codeine. *Formulary*, 1835.

Extract of opium, deprived of morphine, is much weaker than the water extract—gr. iv equal $\frac{1}{2}$ of morphia.

Extract, deprived of narcotine, same as watery extract.

Narcotine, 3j, administered in twenty-four hours, produced no effect. (Magendie). It is not used by British physicians. T.]

PRUSSIC OR HYDROCYANIC ACID.

The most violent poison at present known, diluted with water and in small doses, it acts principally on the nervous system, diminishes muscular sensibility and contractility, and occasions great prostra-

tion of strength. It is employed internally as a sedative in nervous and convulsive coughs, in the access of asthma, whooping cough; in cases of cancers, attended with severe pain, &c. Externally it is used as a topical anodyne, in certain chronic and painful cutaneous affections, or accompanied with itching, and in cases of cancerous ulcers.

[It is also used in pyrosis, obstinate vomiting, painter's colic, irritable uterus, pneumonia, diseases of the heart, phthisis, cerebral fever, &c.]

It is greatly to be regretted that there are the greatest variations in the strength of the medicinal prussic acid of this country. Mr. Everett stated in a lecture delivered before the Medical Botanical Society of London, in Jan. 1835, that he had examined various samples of Scheele's acid, which is usually prescribed in this country, and that the frightful difference of strength had induced him to make the results known, with a view of directing the attention of the medical profession to the evil. Thus the sample of Allen and Co. yielded 5.8 per cent. that of Apothecaries' Hall, London, procured at different times 2.1., and 2.6, and that from several other shops 1.4 per cent. This is a remarkable fact, as each sample was said to have been prepared according to Scheele's formula. Mr. Laming had previously represented the difference from 2.5. to 5 per cent. "Now it is true, says Mr. E., we have no fixed standard, and there ore it is impossible to say, whether Allen & Co's. is too strong, or the others too weak; but thus much is certain, that if a medical man were pushing the exhibition of hydrocyanic acid gradually to a maximum dose, the prescription being carried to a shop where the acid had only 1.4 per cent, and then by some accident or other cause, taken to where Allen's acid was used, a sudden, and I fear, a fatal increase would be the result, for more than a quadruple quantity would be taken. For the possibility of a fatal accident, I need only refer to the case of seven individuals near Paris, being killed by a slightly increased dose, recorded in all the medical periodicals a few years since (*London and Edinburgh Philosophical Magazine*, Feb. 1835). To remedy this evil, Dr. Clarke, Professor of Chemistry, in the University of Aberdeen, proposed in 1831, a process since adopted by Mr. Laming, of decomposing pure cyanuret of potassium with tartaric acid in a common phial, "and the result is," continues Mr. L. "a medicinal prussic acid of extreme purity, necessarily uniform in strength, and the only preparation which will retain its strength unimpaired for any length of time." Mr. Everett, however, contends before the Society that the acid thus prepared was not perfectly pure, and proposed another formula for its substitute. It is this, to dilute hydrochloric acid to the exact

sp. gr. 1.129, and to decompose cyanuret of silver with it. *Op. cit.* Mr. Laming comments on the preceding statements, and contends that his method is as good, and much cheaper (*Lancet*, March 28, 1835). The difference of strength of this acid accounts for the sudden death caused by it in the usual dose, and also the escape after a large quantity has been taken. T.]

Subst. Incomp. Mineral acids, the salts of iron, the sulphates, the chloride, and the nitrate of silver, the oxides of mercury, &c.

[It is doubtful whether the neutral salts decompose it, as nitrate of potass, tartarized antimony, &c., for when combined with these it has poisoned animals. T.]

INTERNALLY. Medicinal Prussic Acid. L. de M. (Prussic acid of Gay-Lussac, 1 part, distilled water $8\frac{1}{2}$ parts). Gr. vi—xv, in a potion. The phial in which this medicine is kept, should be covered with black paper, and should be well shaken before used.

[The phial should also be inverted and kept in a cellar. T.]

The same precaution should be observed with all the preparations of prussic acid.

[The acid rapidly evaporates on opening the phial, and the fluid which remains in an ounce bottle, after having been frequently opened, becomes useless. No more than 3j should be kept in the surgery for use. T.]

Alcoholized Prussic Acid. F. de M. (Prussic acid, 1 part; alcohol, 6 parts). In the same doses as the preceding. This preparation decomposes less easily than the former.

Sirop Cyanique F. de M. (Medicinal prussic acid, 3j; common sirop. ℞j); 3ss—j, in a pectoral potion. Each ounce contains gr. $4\frac{1}{2}$ of the medicinal prussic acid.

The *Hydrocyanic Acid Syrup* of the codex is a dangerous preparation, and ought never to be employed.

Pectoral Mixture. Magendie.

℞. Acidi hydrocyanici medicinalis, 3j;
Aque destillatæ, Oj;
Sacchari, 3jss.

Misce, cochleare modicum mane nocteque.

The dose may be gradually increased to 6 or 8 spoons ul daily; each spoonful, weighing 5 drachms, contains about gr. $2\frac{1}{2}$ of medicinal prussic acid.

Pectoral Potion. Magendie.

℞. Acidi hydrocyan. medicinal, m.
xv;
Infusi hederæ terrestris, 3ij;
Syrupi althææ, 3j.

Misce, sumatur cochleare modicum tertiâ quâque horâ.

Each spoonful contains about $3\frac{1}{2}$ gut. of the acid.

Bols Contro-stimulants. H. of Italy.

℞. Acidi hydrocyan. medicinal, m.
xxx;
Miccæ panis,
Mellis,
Pulveris glycyrrhiæ, â â q. s.

Fiant boli xv, ex quibus capiat, unam secundâ vel tertiâ quâque horâ.

[I frequently order this acid for infants, See *Ipecacuanha*. T.]

EXTERNALLY.

Lotion of Prussic Acid. Magendie.

℞. Acidi hyrocyanici med. 3j ad ij;
Aque lactucæ sativiæ, 3j—ij.

The dose of the acid may be carried to 3iv.

[Dr. A. T. Thomson was the first in this country who used it externally. T.]

The *Anodyne Lotions* of the H. de la Salp. do not differ materially from the above mixture. They are employed in lotions, in cases of tetters and cancerous ulcers, and in injections in cancerous affections of the uterus.

[HYDROCYANIC ETHER.]

This medicine was employed by Magendie in the same diseases as prussic acid; but it excited such insurmountable disgust, that he soon abandoned it. The dose should not exceed six drops. T.]

CYANURET OF POTASS.

It acts in the same manner as hydrocyanic acid, and has the advantage over that medicine of not evaporating or changing its properties. It is employed in the same cases and recently in neuralgic and nervous affections of the heart and lungs.

INTERNALLY. Gr. $\frac{1}{2}$ —j, in pills, or in a potion.

Solution de Cyanure de Potassium or *Hydrocyan de Potasse Médicinal.* F. de M. (Cyanuret of potass. 1 part; distilled water, 8 parts). Gut ij—vj two or three times a day, in a potion.

Sirop d'Hydrocyante de potasse. F. de M. Hydrocyanate of potass, 3j; common syrup, ℞l, ($\frac{1}{3}$ ss to j. in a potion; each ounce contains gr. $4\frac{1}{2}$ of the hydrocyanate).

[This solution should be prepared extemporaneously, as it speedily decomposes. T.]

Pectoral Mixture. Magendie.

℞. Hydrocyanureti potassæ, 3j;
Aque destillatæ, Oj;
Sacchari, 3jss.

Misce.

Dosis cochleare modicum mane nocteque.

Pectoral Potion. Magendie.

℞. Hydrocyanureti potassæ, gut.
xv;
Infusi hederæ terrestris, 3ij;
Syrupi althææ, 3i.

Misce.

Sumat æger cochleare minimum, tertiâ quâque horâ.

Potion of the Cyanuret of Potass. Magendie.

℞. Aque, lactucæ sativiæ, 3ij;
Cyanureti potassæ. gr. ss. ad ij;
Syrupi althææ, 3j.

Misce.

Dosis, cochleare modicum secundâ quâque horâ.

Pills of Cyanuret of Potass. H. de la Pitié.

Rx. Cyanureti potassæ;
Amyli, ā ā gr. iv;
Syrupi simplicis, q. s.

Divide in pilulas viij, ex quibus capiat unam mane nocteque.

Employed in certain cases of convulsions, dyspnœa, &c.

CYANURET OF ZINC.

This preparation acts in the same manner as the cyanuret of potass. It is administered in the same cases. Some practitioners use it also as an anthelmintic.

[It is preferred by the Germans to hydrocyanic acid. T.]

INTERNALLY. As a sedative, gr. $\frac{1}{4}$ —v progressively increased.

As an anthelmintic, gr. j mixed with a little jalop.

Powder of the Cyanuret of Zinc. H. of Germany.

Rx. Cyanureti zinci, 3 ss;
Magnesiæ calcinatæ, ʒj;
Cinnamomi pulveris, gr. xvij.

Divide in chartulas vi, quarum sumat seger unam, quartâ quâque horâ.

Employed with advantage in nervous affections of the stomach, &c.

[CYANURET OF IODINE.]

This substance is not as yet employed medicinally. T.]

CHERRY LAUREL.

Its action is the same as that of prussic acid but less energetic. It is employed in the same cases as that medicine.

INTERNALLY. Distilled water, P. Gut. vj—3 ss, in a potion.

Pectoral Potion. Hot. D.

Rx. Aquæ destil. lauro-cerasi 3 ss;
Jalapii pectoralis, ʒ iv.

Misce.

Dosis, cochleare modicum.

To calm a spasmodic troublesome cough and chronic catarrh.

Sedative Syrup. (Roux.)

Rx. Aquæ lauro-cerasi, 3 vj;
Mucilag. acaciæ, ʒ vj.

Sit mistura, cujus capiat coch. ampl., ter quaterve in die.

In nervous cough, asthma and palpitations.

EXTERNALLY

Anodyne Lotion. (Roux.)

Rx. Aquæ lauro-cerasi, 3 j;
— puræ, 3 iij;

Anodyne Mixture. (Roux.)

Rx. Aquæ lauro-cerasi, ʒ iv;
Etheris sulphur, ʒ j;
Extr. belladonnæ, 3 j.

Used in frictions, in nervous, rheumatic and arthritic pains.

Anodyne Cerate. (Roux.)

Rx. Aquæ lauro-cerasi, ʒ ss;
Cerati simplicis, ʒ j.

Applied to chronic and cancerous ulcers.

BITTER ALMONDS

Possesses the same property as prussic acid, is rarely used in France, but preferred to the acid in Germany.

Hydrocyanic Acid. (Schrader.)

Rx. Ol. ess. amygdal. amar. 3 j;
Alcoholis rectific.;
Aquæ destillatæ. ā ā 3 x.

Dosis, m. ij—iij ex paul aq. c. sacch. secundâ vel tertiâ horâ.

Potion of Distilled Water of Bitter Almonds. (Sundelin.)

Rx. Aq. destil. amygdal. amar, 3 ij;
Sodæ tartatris pulv. 3 ss;
Extracti cynoglossi, ʒ ij;
Aquæ destillatæ, ʒ iv.

Dosis, ʒ ss sæpe in die.

Pills of Bitter Almonds. (Kranischfeld.)

Rx. Amygd. amar. prepar, 3 j;
Sodæ sulphatis, 3 ss;
Ipecacuanhæ pulv. gr. ij;
Extract rubiæ tinctor, q. s.

Coge in massam, et in pilulas lx redige, quarum sumantur tres mane nocteque.

In obstinate cutaneous diseases.

Used in cancerous ulceration of the lips, &c.

DIGITALIS.

In large doses, digitalis very much irritates the gastro-intestinal surface and then acts on the nervous system. In small doses it sometimes augments the arterial pulsations, but in general it diminishes them in a progressive manner. Most authors attribute to it the power of diminishing the morbid secretions and of increasing absorption. It is principally administered as a sedative in nervous palpitations, hæmoptysis, asthma, nervous cough, and towards the end of pulmonary catarrh. It is used in anasarca and other dropsies on account of its diuretic property, and its action on the absorbents. The Italian practitioners regard it as a powerful contro-stimulant, and administer it in large doses in inflammatory diseases.

[Dr. Sanders of Edinburgh and Dr. Epps, are of opinion that digitalis accelerates the pulse, and acts at first as a stimulant. The latter published a valuable lecture in vol. vi, 1834, of my Journal on this remedy. T.]

Subst. Incomp. The sulphate of iron, the infusion of cinchona, and the acetate of lead.

INTERNALLY. *Powder.* Gr. ij—xij and gradually increased to ʒj—3 ss.

Infusion. 3 j—iij to Oj of boiling water.

Teinture. P. Gut. x—xx—xxx.

Teinture Éthérée. P. Gut. x—xx.

(To be continued.)

Foreign Medicine.

Extraordinary Suppression of Arterial Circulation.

M. VELPEAU communicated the following fact to the Société Médicale d'Emulation:—

A woman, sixty years old, was attacked with senile gangrene. The disease commenced in the leg, where it appeared to be stationary for some time. Subsequently it invaded the foot, and the whole lower portion of the leg became black and cold. No putrefaction supervened, and the epidermis remained sound. An inflammatory line of demarcation was formed between the gangrenous and sound portions, and a separation was expected. There were no general symptoms, and the digestive canal was in good order. Amputation was considered practicable, and would have been performed, when all at once delirium came on, the red line of demarcation disappeared, and the gangrene extended. For some days back no arterial pulsations are perceptible, even in the carotids, which, from the emaciation of the subject, may be easily felt, and which are hard and unyielding, as if filled with some coagulum. The mortified parts are cold, and their temperature lower than the surrounding atmosphere; the thermometer being at 15 deg. in the hospital ward, it was only at 2 deg. on the limb.

M. Velpeau asks, "How is it possible for this woman to exist without arterial circulation? Even the heart only beats with a dull and insensible trembling, as in the worst cases of cholera. Yet withal, the digestive and pulmonary organs perform their functions, the tongue is clean and moist, the mind clear. Yesterday, however, her expectoration was tinged with blood; probably the respiratory organs are becoming embarrassed, and the death will reveal the cause of a disease at present supposed to exist throughout the whole arterial system."—*Gazette des Hôpitaux*, April 7.

In the same periodical of the 11th of the month is an account of the post mortem examination of the above case.

During the three last days of her existence the patient expectorated black, sooty matter, resembling portions of darkened liver or spleen; to the last the digestive organs and the mind remained perfect.

In the brain, one of the basilar arteries was stopped up by a small concretion; the end of the nose was in a gangrenous state. The right lung was completely converted into spleen-like matter; there were also some old adhesions. The left lung was less changed, but still exhibited a similar kind of alteration.

The state of the vascular system did not give a satisfactory explanation of the phenomena observed in life. There were no lesions of the heart's orifices, except a small indura-

tion in one of the valves, which had no connection with gangrene. From the arch of the aorta to the lower extremities, the arteries were of a black-cherry redness throughout. M. V. remarks that this colour is not in this case a sign of inflammation, because the texture of the internal arterial membrane does not permit of its inflaming. This redness is caused by the mechanical application of the colouring matter of the blood to the internal vascular surface, and is the result of imbibition.

A large clot of blood was found in the lower part of the sphacelated limb. The venous tissue was somewhat thickened, but bore no marks of inflammation. From the preceding facts M. Velpeau concludes:—

1. That senile gangrene is not the consequence of inflammation of the arteries.
2. Nor does it depend on an affection of the blood, for in that case the viscera would also be smitten by it.
3. Nor on the stoppage of the arteries, for there was no such stoppage in this case. Neither can this gangrene be owing, as some have said, to food containing narcotico-acrid matters—ergot of rye, for instance.
4. That such matters have their own peculiar action on the system.
5. That there is no true division of the disease into gangrene of the rich, and gangrene of the poor.

On the whole, he is inclined to side with those who attribute this disease to the annihilation of the contractile function of the heart.

New Method of Effecting a Radical Cure of Hernia.

M. Gerdy proposes, 1. To push forward with the finger the skin, getting it over the finger like a glove, intruding it into the herniary aperture and canal.

2. To fix the extremity of this intruded sacciform process of skin to the anterior parietes of the herniary canal, by several stitches.

3. To inflame the cavity of this sac by ammonia, in order to establish adhesions between its surfaces, and thus obliterate the cavity.

4. To assure success by closing the external orifice by a few stitches.

This operation is but slightly painful, may be performed without making any incision, and closes the herniary orifice and canal with solid flesh. The adhesion was complete on the seventh or eighth day in a patient on whom M. Gerdy operated on the 12th of March, and who is now quite cured of the hernia. He operated in a similar manner on another patient on the 27th of March.

Reviews.

Hérissou on the Sphygmometer. Translated by Dr. E. S. Blundell, with an Improvement of the Instrument and Prefatory Remarks by the Translator. 8vo. pp. 62. London: 1835.

SMALL improvements in medicine are exceeding good when too much noise is not made about them; but we would advise ingenious men not to forget "*parturiunt montes.*" &c.

The sphygmometer, as invented by Dr. Hérissou, has already been sufficiently described in the medical journals of this country; we shall therefore only notice the modifications made in the instrument by the translator, Dr. E. S. Blundell, who thus mentions the defects in its original construction, and his own contrivances for obviating them.

"The first inconvenience which I have experienced when applying the instrument to the wrist of the patient, and which I consider of the utmost importance, is the difficulty of steadily keeping up and retaining with the hand an unvarying maximum of pressure, sufficient to make the mercury ascend to 25 deg.; to accomplish which, with the instrument as invented by Dr. Hérissou, requires more than ordinary tact, and it is to this circumstance, probably, that we are to attribute the discrepancy between the results of the minutes of the two observers, requested by the Commission of the Academy, to make their observations with the sphygmometer on the same patient*.

"The second inconvenience occurs, when the instrument is removed from the wrist of the patient, on account of the column of mercury not readily descending into the reservoir, but lingering for several minutes at the bottom part of the glass tube. This defect, which is probably owing to the quicksilver having acquired an increased temperature during its contact with the skin, obliges the operator to wait several minutes, until the mercury has returned to its former temperature, and sunk into its original station, before he can close the stop-cock, and thus shut out the communication between the reservoir and the glass tube; if this precaution be not attended to, a portion of the metal is liable to escape by the aperture at the top of the tube, and the accuracy of the instrument is thereby destroyed.

"To obviate the first of these inconveniences, I have succeeded, after repeated experiments and trials, in an invention, which

transfers the pressure to an apparatus, instead of confiding it to the hand, and by which the operator can increase or diminish the pressure, as the case may require.

"By the aid of the above improvement, another most important result is obtained, for, as the sphygmometer is firmly fixed in a vertical position over the artery, the hands of the practitioner are perfectly at liberty to note down any phenomena that may arise.

"The improvement which I have made in the construction of the sphygmometer, in order to avoid the second inconvenience, consists in placing the stop-cock nearly an inch higher, as close as possible to the insertion of the capillary glass tube into the stem, so that, the instant the instrument is removed from the pulse, the operator turns the stop-cock, and the mercury is secured."

Dr. Hérissou believes that the sphygmometer is of great utility in the diagnosis of organic diseases of the heart, especially at the early period, when remedial means can alone be effectual; and when, in his opinion, the ordinary methods of exploration entirely fail in detecting them. For the benefit of such of our readers as may be sphygmometrically inclined, we shall briefly note the signs of those organic lesions of the heart to whose detection the instrument is alleged to be applicable."

Contraction of the Right Auriculo-Ventricular Orifice.

"In the contraction of the right auriculo-ventricular orifice the sphygmometer presents this peculiar phenomenon: the column of mercury does not always descend to the point from whence it started, or it requires two intervals to reach that point; it is surprised near the middle by an incidental impulsion which divides it."

Right Ventriculo-Pulmonary Contraction.

"As the ventricle makes considerable efforts to overcome the obstacle opposed to the passage of the blood into the pulmonary artery, it produces in the heart all those movements which we are accustomed to denominate palpitations, which are extremely violent, and in no relation whatever with the action of the artery. Hence the pulse is feeble, trembling, agitated; it presents the same sphygmometric signs."

Left Auriculo-Ventricular Contraction.

"The movements of the heart are soft; the pulse is feeble, irregular, intermittent, unequal, but much more so than in contractions of the orifices on the right side; and I find a satisfactory reason for it, in the chemical difference of the blood which reaches the ventricle. Indeed, if the blood arrive slowly into the lungs, their action is diminished; if, on

* "Vide Athenæum, No. 373, Dec. 20, 1834, p. 922."

the contrary, the blood get there with facility, the action of the lungs is increased. In the first case, the blood being less oxygenated, and consequently less stimulating, imparts a moderate activity to the left cavities; in the second case, this activity, on the contrary, will be very great, for the blood will have regenerated itself in a more easy respiration, and the action which it exercises upon the left cavities will there produce very considerable activity, particularly if it experience any obstacle in its passage; the consequence as regards the pulse in that case is a greater irregularity; it also may happen that the left ventricle ceases to act until it has been able to admit a certain quantity of blood. Under both circumstances, the arteries are almost empty, and this state is clearly proved by their sinking under the sphygmometric column which descends below its level, in the proportion of one, two, and even three degrees, according to the volume of the explored artery, and the power of the obstacle which opposes the passage of the blood into the left ventricle."

Ventriculo-Aortic Contraction.

Here the same vacuity of the arteries is indicated by the same sphygmometric signs as in the preceding case.

Hypertrophy of the Heart without any Contraction of the Orifices.

"The pulse is regular, but unequal in its contractions; it presents this anomaly, that the column of mercury, after having been elevated to a certain number of degrees, we will say 3 or 4, ascends suddenly by intervals to 8, 10, and even 15 degrees. A simple hypertrophy of the left ventricle of the heart is constantly exhibiting this peculiar character of the pulse. The dilatation of the left ventricle and of its auricle, presents the same sphygmometric signs as those of the auriculo-ventricular and the ventriculo-aortic contractions. Auscultation, percussion, mensuration, and the examination of the other vital functions, will serve to distinguish advanced organic lesions from the contractions or vegetations which are beginning to develop themselves."

The sphygmometer used for the heart must, of course, be on an enlarged scale; in other respects it is similar to the small one used for the pulse.

A table is added, in which necroscopic researches are recorded, corroborative of the diagnosis afforded by the sphygmometer.

For our own part, we have very great confidence in our fingers for the exploration of the pulse, and no small faith in our ears, assisted by the symptoms, for that of the heart; nevertheless, we cannot see any rea-

son why our brethren should not, each and severally, provide themselves with sphygmometers, large and small, and proceed straightway to bring the merits of this ingenious instrument to the test of experience.

—o—

EXTRAORDINARY CASES OF POISONING
WITH ARSENIC.

We quote this case in full, though some of the details are rather too minute for many of our readers; but if we omitted them, the narrative would be imperfect. The cases are thus recorded in a French Journal:

A case of extraordinary depravity came on before the Court of Assizes of the Hesse-Hernane (Mayence), on the 22d March last, and occupied the court for the four following days consecutively. It was the trial of two women, each charged with having poisoned her husband, and one of them with having, in addition, poisoned her father, her mother, three of her children, and her paternal uncle. The judicial annals afford few instances of so shocking a series of crimes as that developed in the Court of Mayence in these five days.

Gregoire Toll, and his wife Regina Hof, working people at Abenheim, in the province of the Hesse-Rhenane, the *ci-devant* department of Mont-Tonnere, were entitled to some considerable property upon the death of Mathias Toll, the brother of Gregoire. They had both the reputation of honest and industrious people. They had two children; a son, as a conscript, entered the French service in the year 1811, and disappeared in the Russian campaign; and a daughter named Marguerite, one of the two prisoners, who, in the absence of her brother, conceived the idea of getting possession of the inheritance, to which she would be eventually entitled, by the most infamous means. Having naturally a taste for pleasure, and the advantages of a handsome face and beautiful person, Marguerite devoted herself to *fetes-champetre* and other light amusements, in the enjoyment of which she was encouraged by her parents, of whom she was the idol; and when, with all their economy, they could not supply the means, she contrived to procure them by clandestinely selling the fruit or other produce of the farm, the necessary concealment of which led to falsehoods, and from thence hypocrisy became the prevailing feature in her character.

At one of these *fetes-champetre* she became acquainted with Leonard Jaeger, a farm servant at Abenheim, whom she married in August, 1811, against the will of her parents. Of this marriage there were seven children. Her dissipation and aversion to industry brought trouble into her family, and frequently caused a quarrel between her and her husband.

Jaeger, despairing of her amendment,

himself up to debaucheries, to enable him to indulge in which he contracted usurious engagements with some Jews, and thus the patrimony of Marguerite was dissipated in the lifetime of her father and mother, whose reproaches only inflamed the rage of their son-in-law, and caused him frequently to treat his wife with great brutality. Once, when cracking his whip in a passion, he cut out one of his eyes, and shortly after, in a fit of intoxication, he broke a leg. The least contradiction made him mad, particularly if it related to domestic affairs.

Things went on in this state until the death of Mathias Toll, the brother of Gregoire, and uncle of Marguerite Regina Hof, the wife of Gregoire, after languishing for some time in consequence of the misconduct of her son-in-law, died in 1826, and Gregoire, the father, died 1830. The deaths of these persons, who were in years, appeared natural events, but the catastrophes which succeeded excited suspicion. Leonard Jaeger died in August, 1831, aged 37, and in the December following the grave opened for three of his daughters, aged three, five, and ten years, respectively. It was generally reported that symptoms of poisoning were discovered in the last of these deaths. The widow Jaeger conducted herself with unpardonable levity on the death of her husband, and several expressions used by her were related, which showed the little affection she felt for her children. The magistrate of Abenheim enjoined the Justice of Peace to investigate the case. The body of Catherine Jaeger was disinterred. It was inspected by professional men. The contents of the stomach and bowels were analysed by chemists, but no trace of poison was found, and the inquiry led to no further result.

These proceedings might have been a salutary warning to Marguerite Jaeger if her depravity had not led her to another crime. The annihilation of the little patrimony which she derived from her father and mother reduced her to the necessity of putting her two surviving children out to service, the two others having died in 1829.

Towards the end of July, 1833, she herself entered as servant into the family of Jean Philippe Renter, an innkeeper at Worms. He was a man of substance, with a wife and four children, but this family was also a prey to conjugal strife. Renter by degrees neglected his business, and gave himself up to intoxication. Quarrels with his wife frequently succeeded, which she bore with resignation, but there was no reason to presume that she meditated to relieve herself from her situation by an attempt on the life of her husband, whose health was visibly on the decline from the immoderate use of spirituous liquors. This horrible idea, as appeared in the sequel, was suggested to her by the widow Jaeger.

Renter fell suddenly sick on the 27th of August, 1833, and was carried off in two days. A few weeks afterwards the widow

Jaeger herself was conveyed to the Hospital of Worms. Her malady was considered very dangerous, and despairing of her recovery, she made a discovery to the physician of the hospital, which left no doubt that Renter had perished by poison. The Commissary of Police soon visited the widow Jaeger, and interrogated her, and received from her a fresh confession. Contrary to expectation she recovered, and repeated the same story. The investigation, commenced in the year 1831, after the suspected deaths of the three children, was resumed. This unnatural mother, wife, and daughter, explained in full detail the means employed for the destruction of her victims. Her method did not consist, like that of common poisoners, in throwing arsenic in powder into their food. She boiled a certain quantity of arsenic in a pint of water, strained the liquid when cold through a piece of linen, and mixed this water in a glass of wine, a cup of milk, or some broth, and the result was, the arsenic thus extremely divided could not be discovered in the intestines of the person to whom it was administered. Professional men to whom she explained her diabolical process made an experiment with it upon a calf and a pig. These animals died with astonishing rapidity, and their bowels on examination presented no trace of poison.

Being interrogated as to the manner in which she was initiated in such secrets, she pretended at first that a diplomatist, sent from a foreign power, and decorated with several orders, having lodged for some time at the inn of Renter, had communicated to her this convenient mode of getting rid of an enemy, and at the same time securing impunity for herself. More lately she said it was her own father who had imparted to her the secret; that burning with a desire to appropriate to himself the succession to the property enjoyed by his brother Mathias, he had taught her how to get rid of her uncle. That with this view he had studied the use of poisons, and discovered things which the ablest chemist considered impossible.

This woman, in her defence, displayed extraordinary presence of mind, and answered every objection; but she could not deny that she had taken the lives of her father, mother, and husband, although she employed the most singular artifice to palliate those horrible crimes. As to her children, she pretended they had been poisoned through mistake. She kept in reserve a decoction of this arsenic, prepared after a method which a person unknown, or her father himself, had shown her; and that her daughters, finding this bottle, had the curiosity to taste it, so that she had nothing to reproach herself with on account of their deaths. The life of the innkeeper of Worms she said she attempted only from compassion for the woman Renter, and after long entreaty.

The woman Renter was far from agreeing on this point with her accomplice. If

she was to be believed, she was ignorant that the fatal beverage contained arsenic. She thought it was only a drug to cure him of his passion for brandy.

The Jury found both prisoners Guilty—the former of having poisoned her father, mother, her paternal uncle, her husband, and her three daughters, and both as accomplices in the poisoning of Renter, and the Court passed upon them sentence of death.

[These cases are by no means clearly stated, nor satisfactory to medical jurists. They are within the range of possibility, though exceedingly improbable. The frequent administration of small quantities of arsenic mixed with food might induce gastro-enteritis, but that very small quantities could cause a death in two days, as in the case of Renter, is contrary to the observation of the most experienced physicians and toxicologists. We have stated in our translation of the Practical Formulary of Hospitals, that Fowler's solution administered freely in agues often destroys life; but not so suddenly as in one of the cases above related. These cases remind us of the slow poisoning in former ages, if we except the case of Renter.—ED.]

On the Employment of Nux Vomica and its Preparations in Dysentery.

THE able editor of our contemporary, the *N. A. Archives of Medical and Surgical Science* states, that having been particularly embarrassed and disappointed in the management of dysentery during the two last autumns, in the Baltimore Infirmary, he has been within a short time induced to make trial of the nux vomica in some cases of this disease. "We have as yet only had an opportunity of using it in a few cases," he observes, "and those not of the worst character, yet so difficult to manage, that some of them had previously resisted all our remedies. The cases selected were those which were not attended with much febrile excitement, but which were characterized by frequent calls to stool, considerable griping and bearing down, and an inability to pass any thing but mucus, or that material streaked with blood. In some of the cases, the remedy, though certainly beneficial, was not competent alone to accomplish a cure; in others, its good effects were so striking, as to inspire considerable confidence in its virtues, and to induce us to make this notice, and with the view of inciting others to give it a fair trial under similar circumstances. We do not wish to recommend it to the exclusion of other means, or to inspire a hope that it will be found capable of itself of curing the disease in a large number of cases. But from what we have seen of its effects, we feel assured that it will be found a useful adjuvant, and that in some cases at least it will afford relief when other remedies fail.

"We recommend at first to administer the nux vomica in powder, in doses of seven grains, three times a-day, as recommended by Vaux of Ipswich, England. In one individual, to whom the article was administered in this form, the good effects were prompt. The griping, tenesmus, and frequent calls to stool were speedily checked; the discharges became natural, and the patient, who had suffered much, and had failed to obtain relief from the treatment previously prescribed, expressed himself delighted with the remedy. It was also beneficial in other cases, as were the alcoholic extract of Pelletier, administered in doses of two grains, three times a day, and the strychnia, given in the form of an acetate, in doses of 1-12th to 1-6th of a grain, formed by dissolving the strychnia in acetic acid. Our comparative trials of the different preparations of the article have as yet been too limited to enable us to decide which deserves the preference; but we are inclined to prefer the powder, and next to that the extract. It will perhaps be beneficial to combine with whatever form is employed, a small quantity of opium or some of its preparations."

The good effects of nux vomica in several of the affections of the mucous membrane of the digestive organs, have long been known, but it is highly probable that the remedy has not been so generally employed as it deserves. Hagström, a Swedish physician, was, we believe, the first who recommended it in dysentery, and his testimony in its favour was of the most flattering character. The celebrated Hufeland states that he derived great benefit from it in the treatment of epidemic dysentery; and Thomann remarks, that he has seen it effectual in allaying the tormina, and abating the inclination to go to stool. Richter observes, in reference to the efficacy of this remedy in dysentery, that the extract, like opium, tends directly to allay the irritation of the alimentary canal, and subjoins, that combined with the article just mentioned, it proves beneficial where opium alone fails to do so. The following is the form in which he administers it:—*Rx. Extract. nucis vomic. ℥ss; Mucilag. gum mimos. ʒi; Aquæ font. ʒvi; Syrup. althæi, ʒi. M. S. Two table-spoonful every two hours.*

"By Most, a recent writer, this article is especially recommended in what he denominates *pituitous dysentery*, and he remarks, that when the disease is protracted, the article may be administered in the following form for several days in succession, with great advantage:—*Rx. Nuc. vomic. ʒi; Infunde in aqua ferv. q.s. Digere per ½ hor ut reman. ʒvi; Col. adde Tinct. opii simp. ʒss. M. S. A table-spoonful every two hours.*

"We find the following very flattering account of the efficacy of nux vomica in dysentery, in Armstrong's Lectures, recent-

ly published:—‘A friend of mine, Mr. George Vaux, of Ipswich, has tried a remedy for sixteen years, in about two hundred cases (*i. e.* in dysentery), and the result has been so successful, and so remarkably uniform, that I feel it my duty to mention the treatment here. This gentleman gives in dysentery, or inflammation of the mucous membrane about the colon, seven grains of *nux vomica* thrice daily. It neither purges nor constipates, but removes the inflammation, and healthy evacuations follow. Mr. Vaux, who resides in London, bears similar testimony to the value of this remedy, and I strongly recommend it to your notice. I shall certainly try it in the next case I meet with. It seems to operate as a kind of specific.’

“By Mr. Frisch, a German physician of celebrity, the remedy is highly recommended. He remarks, that in those forms of diarrhoea dependent upon a subacute inflammation of the mucous membrane of the intestines, which are attended with frequent discharges of tenacious mucus, and much griping and tenesmus, no remedy is so effectual as *nux vomica*. Its efficacy in diarrhoea has also been testified by others. In a case of chronic diarrhoea, in an individual of a nervous temperament, Professor Récamier administered the alcoholic extract of *nux vomica*, in doses of $\frac{1}{4}$ th of a grain, with complete success, after various remedies had been resorted to ineffectually.

“From these remarks it will be seen that the remedy is at least deserving further trial. To expect it to perform the part of a specific would be an absurdity, nor would it be reasonable to expect much from it in the acute stage of dysentery. But after suitable depletion, and especially when the disease is verging upon a chronic form, we doubt not it will be found useful. Our own experience with it, as yet, has been limited; but we propose to it a fair trial, and in the mean time, as truth is our only object, we shall be glad if these observations should serve to induce some of our professional brethren to test its efficacy. Should any of them do so, we should be pleased to receive the results of their experience.”—*American Journal of the Medical Sciences*, Feb. 1835.

—o—

Singular Condition of the Knee-joint of a New-born Infant.

DR. D. W. BARD, of Troy, Vermont, has communicated to our contemporary, the *Boston Medical and Surgical Journal* (Nov. 26, 1834), a remarkable case, in a new-born infant, in which “the leg turned up forward on the thigh, the bottom of the foot presenting directly forward, the toes turned toward the face of the child, and the heel from it.” The attendants were not aware of any injury being sustained during the delivery, which had been natural, and accomplished

by the unaided efforts of nature. Dr. B. found that on drawing the leg gradually and gently towards himself, it immediately assumed its natural position and shape; but when left to itself, it began directly to move upward; the knee flattened upon the top; swelled out a little beneath, but none on either side. When the leg had arrived at about a right angle with the thigh, its motion became more rapid, till it was checked by the clothes, or the integuments of the lower part of the thigh and upper part of the leg. It was easily drawn back; and when the leg had arrived at nearly a right angle with the thigh, the amount of force required to carry on the motion was still less, and continued to diminish until the limb became straight. Flexion of the leg upon the thigh was performed with the usual ease. No motion of the limb appeared to give the child pain. The limb was confined in a proper position by bandages, for a short time, and the leg did not afterwards show any inclination to return to its unnatural situation. The child did well, and when it began to use its legs no difference could be discovered between them.”—*Op. cit.*

THE HONEY OF TREBIZOND.

—

IN a letter from Keith Abbott, Esq., to the Secretary of the Zoological Society, is an account of this famous honey, spoken of by Xenophon as having produced the effects of temporary madness, or rather drunkenness, on the whole army who ate of it, without causing any serious consequences. “It is supposed to be,” he observes, “from the flower of *azalea pontica*, that the bees extract this honey, that plant growing in abundance in this part of the country, and its blossoms emitting the most exquisite odour. The effect which it has on those who eat it, is, as I have myself witnessed, precisely that which Xenophon describes. When taken in a small quantity, it causes violent headache and vomiting, and the unhappy individual who swallows it, resembles as much as possible a tipsy man; and a large dose will completely deprive him of all his senses.”

ROYAL HUMANE SOCIETY.

FROM the report of this Society, it appears that 25,000 persons have been rewarded for risking their lives to preserve others; and more than 60,000 persons rescued from apparent death.
